De Palma Wins Twin City 150-Mile Race

His Mercedes Averages 90.8 M.P.H. for the Distance—Aitken Second—Christiaens Third —Poor Gate Almost Causes Postponement

MINNEAPOLIS, Minn., July 4 — *Special Telegram*—Ralph De Palma at the wheel of his cream-colored Mercedes was the bright particular star to-day of the sadly curtailed Mid-Continent races at the Twin City speedway. The veteran driver tooled his German-built American mount into first place early in the 150-mile event and held that position for a win. His time was 1:38:49.20, an average of 90.8 m.p.h. Aitken in the Peugeot put up an exciting battle but finished second, 1 min. and 25 sec. behind De Palma. His time was 1:40:14.5. Christiaens, whose English Sunbeam led De Palma for the first 8 miles and again from the twentieth to the fortieth mile posts and menaced De Palma's supremacy for 65 miles, took third in 1:43:28.75. This was 2 min. behind Aitken and over 5 min. behind De Palma.

The remaining four cars of the seven to finish in the money were Milton, Duesenberg, fourth, time 1:44:11.95; O'Donnell, Haskens special, a Duesenberg machine, fifth, time 1:47:37.95; Sorenson, Marse, sixth, time 1:56:14.45; Muller in Dans L'Argent, a special job with a Hudson motor, seventh, time 2:1:18.20. The last car to finish just barely lived up to its name Dans L'Argent, or "in the money."

Race Nearly Called Off

Until almost 4 o'clock prospects of any race at all were dubious indeed, not that there were not starters enough, for fourteen cars were ready for the signal, not that the track was any worse than normal, for, while there were clouds and showers in the morning the sky was clear and the sun shining by 11 o'clock, but because the promised $20,000 supposed to be hung up as prize money for the four events of the day was not forthcoming. The program scheduled four races, 150 miles, 50 miles, 20 miles and 10 miles, respectively, with the big event of 150 miles to start at 2 o'clock, but at that hour the grandstands and parking spaces were disappointingly bare, the expected crowd having failed to materialize, due to the morning's rain and to lack of proper advertising of the races. The speedway management had counted on the gate receipts to provide the funds for the prize money, and seemingly the total of the advance sales and the gate receipts did not amount to much more than $8,000 of the $20,000 announced prizes. W. C. Barnes, A. A. A. representative, refused to permit the race to start until the prize money had been placed in his hands as required by the rules of the association. The sparsely-settled grandstands were becoming impatient by 3 o'clock when Barnes called a meeting of the drivers, who first offered to stage a 10-mile exhibition for no prize if the management would return their money to the ticketholders. This not being received with enthusiasm by the management, it was decided to run the 150-mile event only for the $8,000 cash and Manager Sperry's check for the balance secured by speedway stock, Starter A. C. Bennett then sent the fourteen cars away at 3:55, nearly 2 hr. late.

The afternoon events began by the review of the State troops by Governor Burnquist, and this also may add to the difficulties of the speedway management for the contract with the State that the exhibition of the militia calls for a payment of 10 per cent of the gross receipts to the soldiers' fund. Now the State threatens to bring suit.

(*Continued on page* 42)

Buick Adds a Four

NEW YORK CITY, July 1—The General Motors Co. has again entered the four-cylinder field with a four-cylinder runabout, known as D-4-34, and touring car, known as D-4-35, selling at $650 and $665, respectively, f.o.b. Flint. The company will concentrate on this model and its small six, having discontinued the large six.

The new four-cylinder model will be designed for an initial production of about 75,000. The motor is of the same overhead valve construction as the present six and is 3⅜ by 4¾, developing 35 brake hp. Other specifications include: 106-in. wheelbase, Delco ignition, Stewart vacuum fuel feed, 31 by 4-in. non-skid tires, three-quarters floating rear axle, semi-elliptic springs on both front and rear, the front being 30 by 2-in. and the rear 48 by 2. The car has three speeds forward and is geared 4 to 1 on high.

New York and Chicago Show Dates Jan. 6 and Jan. 27

NEW YORK CITY, June 30—The National Automobile Chamber of Commerce has announced the 1917 show dates. The New York show will open at the Grand Central Palace Jan. 6 to 13, inclusive, while the Chicago date is Jan. 27 to Feb. 3, inclusive.

Want Funds for Aeroplanes

Aero Club Appeals for Assistance in Sending Planes to Mexican Border

NEW YORK CITY, July 5—The Aero Club of America has sent out a strong appeal for funds to enable private enterprise to raise a fleet of military aircraft which can be presented to the government. In the letter the club states that it feels Congress should provide the money. The U. S. army to-day has but twelve aeroplanes and there are but fifteen army aviators, yet every aeroplane is worth 1000 soldiers in campaigns such as that which may still have to be fought along the Mexican frontier.

"Aeroplanes are necessary to protect the lives of the thousands of soldiers participating in the Mexican expedition. The Aero Club of America is mobilizing the licensed aviators available, equipping them with high-powered aeroplanes, and keeping them in readiness to await the call of the War Department, which will gladly avail itself of this reserve in case of need. It will cost between $400 and $750 to train each aviator, and between $8,000 and $10,000 each for the high-powered military aeroplanes."

Peterson Joins Alloy Steel Spring

JACKSON, MICH., July 1—F. J. Keiser, superintendent of the Alloy Steel Spring Co., has resigned, and is succeeded by Gustave Peterson, now with the Carnegie Steel Co. at Detroit.

Fergus Car for Next Year

NEW YORK CITY, July 3—In a large office at 80 Maiden Lane, this city, J. B. Ferguson is working on the drawings of the Fergus car which created such great interest at the last New York show, in order to get it into shape for manufacturing. Up to the present the exact location of the plant has not been chosen, but it is certain to be close to New York. Mr. Ferguson expects to have the first cars ready for the market in about 10 months and plans an output of well under 1000 for the first year. It has been necessary to raise certain portions of the chassis to suit American road conditions, but the car will be altered in no essential feature otherwise.

Loomis Resigns from Packard

DETROIT, MICH., June 28—Allen Loomis, for the past 10 years with the Packard Motor Car Co., this city, has resigned his position as research engineer to devote his attention to private engineering. An announcement regarding the details of his new work will be made after Mr. Loomis' return from his summer home at Higgins Lake. During his connection with the Packard company, thirty-nine patents were granted Loomis, many of which are embodied in the current Packard cars.

Earle and Boggs Leave Continental

DETROIT, MICH., June 29—L. H. Earle, sales manager and G. A. Boggs, assistant sales manager of the Continental Motors Co., this city, have resigned and will become actively engaged in business together in the East.

Elliott, Haynes Production Manager

GRAND RAPIDS, MICH., July 3—E. M. Elliott, formerly in charge of the production of the United Motor Truck Co., Grand Rapids, Mich., and since then in charge of sales of the Mais trucks, has been made production manager of the Haynes Automobile Co., Kokomo, Ind.

Night stop of record-breaking King eight for supplies. Time and duration of stop checked by A. A. A. observer

King Covers 10,850 Miles in 2 Weeks

Averages 32 M.P.H. — Parallels 2 Years in Owners' Normal Service

SHEEPSHEAD BAY, June 29—Just a little after noon to-day the King eight-cylinder car, which has been undergoing a non-engine-stop test for the last 2 weeks, rolled across the finishing line of the board track here having covered practically 10,850 miles without a falter in its power plant.

The object of the test, which started at noon on June 15, was to demonstrate the stability of the King eight-cylinder engine and to approach a condition of actual service by concentrating the running and operation of 2 years' car service into 2 weeks of test work. To accomplish this the car maintained an average of over 32 m.p.h., including the stops to take on gasoline, oil and other supplies. Excluding the stops the speed was 34.31 m.p.h. The engine ran 24 hr. a day and was not stopped from the moment the test started until it was switched off by F. E. Edwards, technical representative of the A. A. A., before the New York King salesroom late this afternoon.

The test was methodically arranged and carried out from start to finish. It was under direct sanction and supervision of A. A. A. officials, who worked in shifts of 8 hr., observing the running of the car and noting, on the score sheet, the time of each lap around the 2-mile track. The drivers worked in shifts of 5 hr., with a 10-hr. rest period and with the driver rode a mechanic giving a full passenger load in the front seat while in the rear a bag of sand weighing 500 lb. was carried to represent the full passenger load in the tonneau.

The entire 10,850 miles were run upon the speedway except 200 miles which were made upon the roads of Long Island between the speedway and the Motor Parkway and on the Motor Parkway itself up and down the 40-mile stretch from Jericho turnpike to Lake Ronkonkoma. No attempt was made to speed the car excessively but the average was held consistently throughout the run. The car probably made its fastest time when put on the Motor Parkway, as it traveled at times close to 50 m.p.h. over the rolling country traversed by the parkway. Even at this speed, however, due to interruptions to and from the parkway, the average speed while off the board track dropped to about 26 m.p.h., showing the impossibility of maintaining a high average over the open roads.

As a service test of the car, the King company makes the point that this shows

actual performance as well as it possibly can be shown in a test because the distance covered by the car is equal to about 2 years of normal driving and the speed is not very far in excess of that often demanded by the car owner. The King car which made the test was certified by the King company and by A. A. A. officials to be a strictly stock job throughout, even including the details of equipment. This is a Model E car with an eight-cylinder, 3 by 5-in. motor, having an S. A. E. rating of 28.8 hp. and a piston displacement of 282.7 cu. in. The motor is a product of the King plant and follows conventional eight-cylinder practice with the cylinders cast in blocks of four at 45 deg. The valves are on the inside of the V and are operated from a chain-driven camshaft. Cooling circulation is by thermo-syphon, lubrication is by pressure and ignition by single Atwater Kent battery system.

Gasoline is fed by the Carter system to a Ball carbureter. Starting and lighting is by Ward Leonard. The drive is taken through a plate clutch through a three-speed unit plant gearset through a floating American rear axle. The gear ratio used on the test car was a standard 4.25 to 1 and the tires 35 by 4 Firestone plain tread front and non-skid rear. The only fitting on the car which does not coincide with stock practice was an additional speedometer which was installed as a double check on distance. The official distance readings, however, were not taken from the speedometer but measured by the laps made on the speedway. While on the road during Saturday, June 24, while the speedway was occupied by the New York police in their field games, the distance was taken from the speedometers corrected by a coefficient determined from a comparison of the readings and the known distance traveled on the 2-mile track.

Total Stops 160

During the course of the run the car made 160 stops. On 69 of these changes of either driver or mechanic were made. Besides stops for supplies and changes of drivers the other causes for stops were as follows: Testing electrolyte of battery on several occasions, replacing bulbs, oiling universals, oiling speedometer drive, tightening grease cups, tightening fan belt, cleaning gas line, taping leak in gas pipe, tire changes, renewing motor oil, splicing horn wire terminal, steering gear adjustment, and at important distances, such as 10,000 miles, the car was stopped for photographs. Throughout the run no adjustments or mechanical work was done that could not be accomplished by the ordinary owner, this being one of the objects of the test. The weather conditions were very severe during many parts of the run, in one instance the fog being so thick that the driver could hardly stay on the track and m.p.h. There were several thunder storms during the course of the run, three or four of which amounted to practically cloudbursts and also two or three days of steady, misty rain. About half the time the weather was bright and fair.

One of the features of the run was the oil economy. The car averaged 1172.7 miles to a gallon of oil, in spite of the speed, which was considerably in excess of average driving, with the added factor that the motor did not stop running for an instant after the test was started.

Specifications of the King Model E Car

Price—$1,350.
Body—7 pass.
Color—
Make of engine—King.
No. of cylinders—8
Shape—V.
How cast—4.
Bore—3.005.
Stroke—5.00.
S.A.E. hp.—28.8.
Ignition—Atwater Kent.
Carbureter—Ball.
Gasoline feed—Carter.
Lighting system—Ward Leonard.
Clutch—Plate.
Gearset—Selective three-speed.
Wheelbase—120 in.
Tires—34 x 4.
Wheels—wood.
Speedometer—Stewart.
Make of axle—American.

—

Jordan Starts Manufacturing

CLEVELAND, OHIO, July 3—The new plant of the Jordan Motor Car Co., 1054 East 152d Street, has begun production of cars for the trade. The specifications of the new car include the following: Six-cylinder Continental motor; Timken bearings and axles; Bijur starting and lighting system; Stromberg carbureter; Bosch ignition; Brown-Lipe transmission and clutch; Parrish frame; Willard storage battery Stewart-Warner equipment; Gemmer steering gear and Firestone tires.

Repair Plant for U. S. Army Trucks

7000 Machines to Be Kept in Proper Condition at Fort Bliss

EL PASO, TEX., July 1—Seven thousand trucks belonging to the United States Government will be taken care of in an immense repair shop located at Fort Bliss, if the plans of the United States Army are carried through.

There are now, or will be within the next few days, a total of 1050 trucks and about 125 touring cars and roadsters in army service along the border. Repairs at present are made at the camp at Columbus or in private plants.

Two thousand trucks and their tenders were asked for early in the week for immediate delivery. Another lot of 4000 was ordered last Thursday.

There will be fifty-two big lathes in the shops at Fort Bliss. Mechanics will be paid approximately $100 a month, but will be required to enlist in the regular army for a period of 1 year.

The contract for gasoline held by the U. S. Government has expired. It called for the delivery of gasoline along the border at 10 cents a gal.

—

Chevrolet Purchases Warner Plant

TOLEDO, OHIO, June 29—The Chevrolet Motor Co. has purchased the plant of the Warner Mfg. Co. on Central Avenue, and will open it, about July 15 as a factory branch.

Artemus Ward, Jr., president of the King Motor Car Co., congratulating driver Grindell at the end of the 1000 miles. Left to Right—C. Jacobs of King experimental department in charge of test, drivers Benson, Cork and Grindell, Artemus Ward, Jr., H. C. Bradfield, advertising manager, T. P. Chase, chief engineer, and G. J. Bates, commercial manager

National Gas Engine Assn. Members Advocate Affiliation with S. A.E.

Chicago Meeting Discusses Advantages of Close Co-operation With Other Engineering Bodies—Many Papers—Views on Kerosene and Tractors

CHICAGO, ILL., June 29—To-day the convention of the National Gas Engine Association came to an end after 3 days in session at the Sherman Hotel. Affiliation with the Society of Automobile Engineers was broached informally at the business meeting yesterday, while John T. R. Bell, engineering representative of the Norma Co. of America, and who is a member of both societies, in the informal discussion, pointed out that the standards committee of the Gas Engine association has been working in very close touch with the standards committee of the S. A. E. and has adopted wherever possible the standards already in force among the automobile manufacturers, and also that two other associations in allied industries, the marine engineers and the aeronautic engineers, have asked to become affiliated with the Society of Automobile Engineers.

Inasmuch as complete plans for the co-operation of these societies have not been worked out as yet it was decided to defer action for the time being. Comment in general was favorable.

The standards committee adopted standard specifications for a number of features of gas engines, and it was notable that recommendations were, in so far as possible, to follow the present standards of the Society of Automobile Engineers. The association formally adopted a standard guarantee for gas engines warranting them to be free from defects in materials and guaranteeing replacement of parts proving defective in material for a period of 1 year. This does not include ignition or other accessories guaranteed by the makers.

At the election of officers the president, secretary and treasurer were re-elected, as were most of the vice-presidents and executive committee. C. E. Bement of the Novo Engine Co., Lansing, Mich., is president, R. H. Brate is secretary, and Otto M. Knoblock treasurer.

Many Tractor Papers

There were a number of papers and discussions on tractors, and another series on various ramifications of the fuel problem. Other papers of interest, from the manufacturing standpoint, included scientific management of factories, uniform methods of figuring costs, ignition selections, reducing shop cost, and an address by Dr. Frank R. Rutter, assistant chief of the Bureau of Foreign and Domestic Commerce, on the internal combustion engine in foreign trade.

That the former low price of gasoline is a thing of the past, is the belief of E. E. Grant, secretary of the Independent Oil Men's Assn. of Chicago, who in an address entitled the Fuel Problem as it Pertains to the Internal Combustion Engine discussed the present factors which have caused the rise in the price of gasoline and the probabilities of the future. He stated that it was his belief the average price of the future would be from 15 to 25 cents, and did not anticipate that the cost to the consumer would be very much less than 15 cents or very much higher than 25, at least for several years. He confirmed the general impression among gasoline users that the demand for motor fuel has become enormous and that quite frequently the quantity of fuel is increased by adulteration. He made a plea for co-operation between oil men and engine makers and proposed an association of gas engine, automobile, marine and aviation engineers, together with the oil men—experts who could work together for the solution of a proper fuel.

Crude Oil Increase 700 per Cent

He brought out the point that during the last 2 years the increase in the price of crude oil has been 700 per cent and in addition to that it often was necessary to pay premiums over the market price. He figured that the consumption of gasoline for 1916 would be 1,934,000,000 gal., but stated that much progress in increasing the yield had been made within the past year, and that at present 2 per cent of the gasoline is made from natural gas. The gasoline from this source has a low boiling point of 65 to 85 deg. Fahr. and a high boiling point of 300 deg. Fahr. He mentioned the fact that a process of pressure distillation for increasing the yield from crude was patented by a Dr. Parker as early as 1907, this antedating both the Rittman and the Burton process patent. He emphasized the need of the development of engines to use low-grade distillates, and stated that when the troubles with Mexico are over that country will be able to supply sufficient crude oil for the entire world. This, however, is not rich in gasoline. Seventy-five per cent of the oil industry in Mexico at the present time is owned and controlled by American capital. Mr. Hall also confirmed the general impression as to the decrease in gravity of motor fuel during the past 2 years. He stated that not long ago gasoline of 76 deg. Beaumé was common. Now it is not over 58 deg. and sometimes as low as 50. Within the next 2 years it will be somewhat below 50 deg. Beaumé. He said that gasoline users are gradually coming to kerosene and that before long we may expect to be using kerosene. He believes that within 5 years engines will be so designed and the distillation process so refined that of the crude oil 75 per cent will be used as fuel and the remaining 25 per cent as lubricant.

In the discussion of E. W. Roberts's paper on liquid fuels present and future, the fact was brought out that in England there has been considerable experimenting with the use of pulverized coal, and in Germany with naphthalene, no one, however, recalled the fiasco of a few years ago with Zoline, which was supposed to be chiefly naphthalene and water. The statement was made that it would not be surprising in a few years to see gas engines using coal as fuel. In confirming this Mr. Knowles stated that his company has been experimenting with coal in solution in water, that it could be pulverized so fine that it partakes of the nature of deflocculated graphite and can be atomized and ejected into a burner just the same as fuel oil, and that subtracting the heat necessary to dispose of the water there would be left 13,000 B.t.u. per lb. from the coal. The chief difficulty with its use in internal combustion engines would be the ashes.

In a paper dealing with tractor engines, W. J. McVicker anticipates a return to favor of steam. "The gas tractor created so much interest that the steam tractor was left in its undeveloped condition and we do not yet know its possibilities. It will not be at all surprising to see a revival in the development of the steam tractor, and it may even become a strong rival of the gas tractor. However, this will depend somewhat on the nature of other fuels available in the near future."

Maxims of Engine Design

The author discussed different types of engines which had been and are being applied to tractors and set forth the advantages and the disadvantages that had been encountered in each, concluding with a statement that a successful tractor engine must have the following qualifications regardless of its type:

1—It must be so constructed that it can develop its maximum power continuously without self-destruction. The element of limited overload must be eliminated because it cannot be controlled.

2—It must start and operate without undue loss of time and must do a season's work with ordinary care and without the services of an expert. Instructions that the user must spend considerable time each day in doing expert work in order to keep it going must be discarded from the instruction books, because time is too valuable during that

period and such advice will be ignored.

3—It must develop its rated power economically and operate successfully with the kinds of fuel common in the locality where it is used.

Possibilities in Small Tractor

In a paper on the modern gas tractor W. A. Horthy stated that the present-day machines are in a state of evolution and a long way from perfection. He considers that purely as a manufacturing proposition, the small tractor with its initial low cost, great flexibility and present-day popularity, seemingly offers the greatest possibilities. No progress in the development of four-wheeled tractors is being made in this country, although much experimenting is done abroad with good success. It seems as if the high price and unusual construction do not sufficiently balance the guaranteed advantages over two-wheel-drive tractors. Regarding kerosene Mr. Horthy holds very strong views which may be summed up as follows:

A few years ago the market was flooded with kerosene attachments. Their disappearance warrants the truth of the assertion that to have a kerosene-burning tractor means a whole lot more than to equip the engine with a special carbureter. There is but one way to burn low grade fuels perfectly in internal-combustion engines, that is the Diesel way. This principle of fuel injection into the highly compressed air of the combustion chamber—this rational burning, not exploding, at 500 to 600 lb. pressure, gives some startling demonstrations of economy and reliability.

—

Hatfield Roadster at $875

SIDNEY, N. Y., June 30—The Cortland Cart & Carriage Co., this city, maker of the Hatfield roadster, suburban car, light delivery and light express cars, and which recently increased its capital from $75,000 to $225,000 to take care of a more active production of its products, is now making distribution of its cars within a comparatively small radius of this city. The company states that it will not build more than a few hundred cars for the next year or so.

The models are equipped with a four-cylinder L-head block engine developing 32 hp., the bore being 3¾ in. and the stroke 4¼. Other features include thermo-syphon cooling; selective sliding gear transmission with three speeds forward; disk clutch positively coupled to transmission; constant level splash lubrication; Connecticut ignition; Stromberg carbureter; Hotchkiss drive with two universal joints; semi-elliptic springs in front and full cantilever, floating in rear; Disco starter; and full floating rear axle.

The model H, three-passenger roadster sells for $875, the suburban car for $800, the light delivery for $820.

2400 Cars and Trucks for U. S.

—

Bids Received for Motor Equipment Estimated To Be Worth $15,400,000

WASHINGTON, D. C., July 3—Bids have been received by the Quartermaster's Department for supplying the Government with 2000 trucks, half of 1½-ton capacity and half of 3-ton size. Simultaneously bids have been made for supplying 400 cars in touring and roadster bodies intended for dispatch carrying and for moving officers rapidly from point to point. The truck order is estimated to be worth about $15,000,000 and the order for touring cars about $400,000.

Naturally the Ford Motor Co. has made the lowest bid for the touring cars, offering them at $440 each, f.o.b. Detroit, and undertaking to complete delivery within 1 week from receipt of order. Another offer is of 400 Elkharts at $975 each, the company stating that it has a large stock on hand. The Colt-Stratton Co. offers 400 Dodge cars at $785, guaranteeing shipment to be started 1 day after receipt of order and completed within 4 days, thus beating the Ford delivery offer by 2 days.

Willys-Overland offers its six-cylinder model for $973.25 or the Willys-Knight at $956.25. Packard offers the standard seven-passenger touring car for $2,475, and has a hundred for immediate delivery.

Maxwell offers forty cars per day at $500 each, f.o.b. New York, or $475 each, f.o.b. Detroit. Other bidders include Reo, King, Velie, Hupmobile and Studebaker, some of these bids being made direct and some through dealers.

Big Truck Orders

On the truck order there have naturally been a very large number of bids, since it is impossible for any one firm to hope to execute the whole order. It is obvious that if this quantity was required hurriedly it would be necessary to buy in tens and twenties from almost every maker. One of the bidders offering the most rapid delivery is the Four Wheel Drive Auto Co., offering fifty-six 3-ton chassis by the end of August and stating that it can speed up at the rate of 224 per month.

The Chicago Pneumatic Tool Co. has 100 trucks of 1½-ton capacity for immediate delivery and can produce 150 per month. White offers two trucks per week, the Locomobile five trucks in 28 days and thirty in the following 3 weeks. Pierce-Arrow offers 700 2-ton chassis, 300 to be delivered by Jan. 1, 400 by April 1 and ten per day thereafter. Packard bid for thirty-three 1½-ton in 2 days after Aug. 1, the subsequent deliveries at the rate of thirty-three each 30 days and also for a certain number of 3-ton trucks. Jeffery has a 1½-ton bid, delivery at the rate of seven per day. Most of the other bids are for small quantities and far too numerous to mention. It is noteworthy that the specifications for the trucks were finally drawn up after consultation with a committee brought together by the Society of Automobile Engineers, including prominent engineers. Several meetings attended by government representatives were held at the S. A. E. office and the specifications as drafted originally were modified in some respects so as to enable greater output in a short time.

—

Homer Laughlin Builds 8-Cylinder Front-Drive Car

LOS ANGELES, CAL., June 28—The Homer Laughlin Engineers Corp. of this city has completed three of the new Homer Laughlin eight-cylinder front-drive cars and the factory is now turning out ten machines on order.

The new Los Angeles built car has been more than 2 years in the rough and now that the factory officials are sure of their product, active car building is to follow. The car weighs less than 1700 lb. and sells for $1,050. The builders have taken over the large factory on Long Beach Avenue, formerly occupied by the McCann Mechanical Works and are building every part of the car with the exception of the electrical equipment, wire wheels and tires.

—

Fostoria Raises Prices

FOSTORIA, OHIO, July 3—The Fostoria Light Car Co., this city, has raised the price of its 1917 touring car to $735; the delivery wagon with an open body to $695 and with a closed body to $715. The width of the rear seat has been increased from 39 to 46 in. and the front seat from 37 to 42 in. The car has a floating rear axle, Remy ignition with distributer and automatic sparker. The car is now equipped with a natural wood cowl dash upon which are located all of the instruments.

—

Pathfinder Starts High-Gear Run

SAN DIEGO, CAL., July 4—*Special Telegram*—Twenty thousand people witnessed the start of the Pathfinder twelve on its high-gear run across the continent today. The start was delayed an hour by reason of officials not being able to check specifications and place seals on the car by 12 o'clock. At 12.30 the crowd around the car in the Plaza de Panama was so dense that police and exposition guards were necessary to clear a passageway.

Simple Tests Show Car Condition

How Acceleration, Speed and Fuel Economy Are Inter-connected—Power and Gear Ratio Relations Analyzed and Explained—Aids for Owners

By Charles E. Manierre

BEGINNING with the issue of April 17, 1913, THE AUTOMOBILE contained a series of four exceedingly interesting articles by Prof. W. C. Marshall on Detecting Resistance and Saving Fuel.

The experiments mentioned by him were made through the use of an English invention known as the Accelerometer. This instrument is about the size of a rather small alarm clock and is laid face up on some surface or bracket on the car where its needle indications can be read conveniently. It contains a levelling screw, but needs only to be strapped in position and is in no other way connected with the car. Its needle indicates on a scale three things only, viz., grade, resistance in pounds per ton, and acceleration in feet per second.

Two things have prevented this instrument from coming into general use, viz., its price, $52.50, and the knowledge of mathematics and physics which seemed to be necessary to its successful understanding.

Professor Marshall, in order not to take up too much space in THE AUTOMOBILE, condensed his articles so that every sentence was concentrated. It must have proved difficult reading except by those to whom acceleration in feet per second per second, resistance, momentum, gravity constants, torque curves and horsepower formulae were a daily diet. Nevertheless his article contained much of vital interest to every car owner and it is by no means necessary to own or use the instrument mentioned to get valuable results from the line of thought he followed.

For the practical man who wants neither exact mathematics nor science and who will never be on speaking terms with a torque curve, the study of Professor Marshall's article suggests two simple tests of the condition of one's car and engine.

Testing for Friction

Every car owner has at times the knowledge that his car is in fine condition and is running its full number of miles per gallon of gasoline. When this is so, let him pick out a convenient spot on the road near his home, bring his car to a definite speed and at a definite point on the road throw out his clutch and coast to a standstill and note the point where the car stops. Thereafter, whenever he wishes to test the friction of his machine from the gearbox to the rear wheels, and the rolling resistance, he can repeat the experiment at the same place and speed and can tell whether all is well, namely, whether he coasts as far. But he must remember that the passenger load, etc., must be the same and the tires must be pumped to a reasonable pressure.

The second experiment is for the engine, and is to be first made when the engine and car are running in extra good condition. It consists in selecting a hill not too steep to be ascended on high gear at, say, about 20 m.p.h. The test consists simply in determining with the throttle wide open what is the exact maximum speed of the car on the hill. Later on when it is desired to test the running of the engine it will first be necessary to try the coasting test; and be sure that some such evil as dragging brakes is not causing trouble. If the coasting test proves satisfactory, then diminished speed on the hill will reveal the need of attention to the engine, which is not delivering its proper horsepower. Of course the diminished mileage per gallon of gasoline will tell the same story, but it will not indicate, as the above tests will, whether the trouble lies in front of or behind the flywheel.

In the hill test, as in the other, the weight carried by the car must be the same as in the original experiment.

An Ability Diagram

Even though one has no intention of putting his engine through a series of exact tests, it is worth while to have knowledge of the subjects of grade, resistance and acceleration, and to have an intelligent comprehension of the facts which are revealed by a diagram showing curves of resistance, torque on several gears and grade. In fact such a diagram for a given car shows very completely its ability. It gives much more information than a mere horsepower curve.

No doubt manufacturers would be only too glad to display such a diagram as showing what might be expected of their respective cars if any considerable part of the public were prepared to appreciate the facts to be gleaned therefrom. In such case of course the diagram should indicate the performance of the car with its normal passenger load. The vertical lines on such a diagram would indicate speed in miles per hour, while the cross lines, beginning at zero at the bottom, would indicate resistance in pounds per ton of 2000 lb.

The first and most important curve would be a coasting resistance curve, starting at zero pounds and zero miles per hour, and sweeping upward to a rapidly increasing rate of pounds of resistance as the speed became great.

This resistance is exactly what would be shown if the car were drawn along by means of a spring balance and the pounds indicated on the balance were divided by the number of tons weight of the car, it being understood that the clutch of the car was depressed.

The resistance so indicated does not include any friction in the engine, as the clutch is depressed, but it does include the friction in the gearbox and the jack shaft, the friction of the universals, the rear pinion and the large pinion of the differential, the wheel bearings and the resistance to rolling of the rubber tires, and finally the resistance of the air. It assumes a hard, smooth road, no grade and no wind.

Air Resistance and Speed

One rapidly increasing factor as speed increases is that of air resistance. It is a necessary part of the coasting resistance and there is no need to give special attention to it except perhaps to say that it is estimated that the average touring car presents a surface of about 12 sq. ft. to the air

through which it travels, and that the air resistance increases as the cube of the speed.

Stated in terms of horsepower, it may be said that at 15 m.p.h. it is almost negligible. At 40 m.p.h. it consumes about 10 hp. and at 50 m.p.h., 21 hp. and soon thereafter has so increased as to consume practically the whole horsepower of the car.

To illustrate how much of resistance the air may offer, it may be sufficient to refer to the nightly meteors, most of which become so heated in the very rare upper atmosphere of the earth as to be entirely consumed in their passage through it.

By reference to Fig. 1, which is reprinted from the article by Professor Marshall, the coasting resistance will be noted as the lowest curve. It would have been possible to include in the diagram below this a curve of resistance due to the air, and also a curve which might be deemed the theoretical curve of resistance, being a curve toward which it would be the ideal of manufacturers to bring their product.

Referring again to the illustration, it will be noted that certain grade curves are drawn which in each case are exactly parallel to the coasting resistance curve and correspond to increased resistance in pounds at the rate of 20 lb. for each 1 per cent of grade. This means that that number of pounds is added to the coasting resistance on the level when the car is required to mount the given grade.

The four torque curves are drawn to show, for each gear setting, the number of pounds of resistance per ton which the engine is capable of overcoming at the several speeds indicated on the diagram.

For example, in high gear, which on the diagram is denoted fourth speed torque at 15 m.p.h., the capacity of the engine is about 230 lb. per ton. It will be seen that this is far more than sufficient to maintain a speed of 15 m.p.h. on the level and is considerably more than sufficient to enable the car to mount a 5-per-cent grade, but will not quite permit it to mount an 8-per-cent grade. At 20 and 25 m.p.h., the torque curve shows substantially the same ability in number of pounds per ton, which means, in view of the increased speed, actually considerably more engine power, but at the same time, by reference to the diagram, it will appear that a grade which at 15 m.p.h. could be climbed, cannot be climbed at 25 m.p.h. and in fact, at about 37 m.p.h. although there is little diminution in the capacity of the engine to overcome resistance in pounds, there is a crossing of the torque curve with the 5-per-cent grade curve, which shows that the utmost speed of the car on such a grade is 37 m.p.h.

If the diagram were continued ¼ in. farther to the right, to the crossing of the coasting curve with the torque curve, we would arrive at the point where the coasting resistance just equalled the ability of the engine to overcome resistance and the maximum speed of the car, about 55 m.p.h., would thus be indicated.

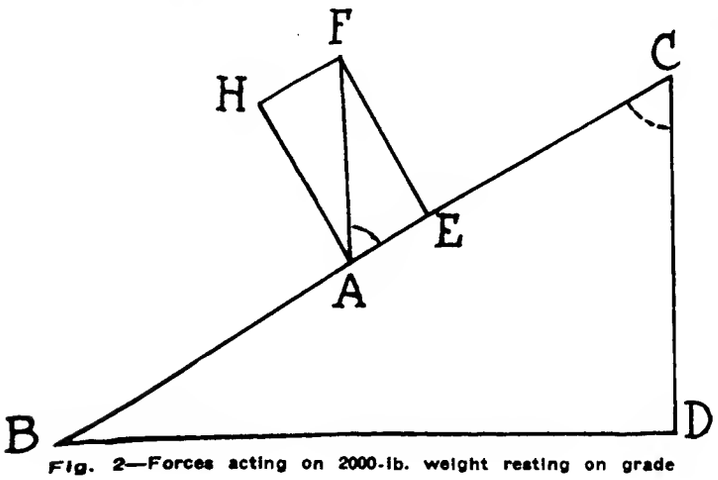

Fig. 2—Forces acting on 2000-lb. weight resting on grade

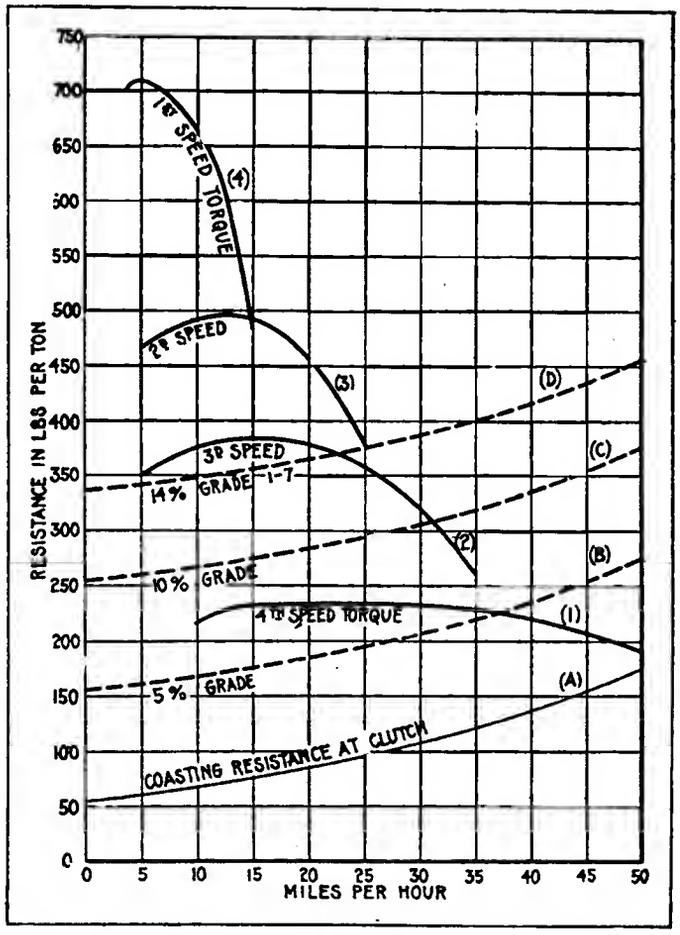

Fig. 1—Relationship of engine torque, gear ratio and grade climbing ability

For low gear, which on the diagram is spoken of as "first speed torque," the increased number of revolutions as compared with the speed of the car enables the engine to overcome a vastly increased number of pounds of resistance running up, at 5 m.p.h., to an excess of 700 lb., and indicating a capacity at that speed to ascend a grade of 35 per cent. As the speed of the car increases, however, the capacity of the engine, as measured by pounds of resistance, rapidly decreases, so that at 10 m.p.h. a 30-per-cent grade would be its greatest capacity and at 15 m.p.h. it would scarcely be able to mount a 20-per-cent grade.

In the second and third gears, the torque curves curve upward from 5 to 15 m.p.h. In other words, the capacity of the engine to overcome pounds of resistance actually increases as the speed increases.

Power and Speed

Of course the increased speed delivers more horsepower but it delivers so much more that the ability of the car to mount higher grades is increased. It is for this reason that on any given grade the car may be able to mount a grade provided it starts at a considerable speed, which grade it could not mount on that gear if starting at a lower speed.

The diagram also indicates that in each case there is a capacity, greater or less, to accelerate on the grade except at the point where the torque curve and the grade curve cross each other, which crossing marks the maximum speed for that car and gear.

While the rolling resistance and the wind resistance and the other items which make up the coasting resistance are more or less matters of experiment and uncertainty, the grade resistance is capable of being stated with mathematical exactness.

In Fig. 2, let the point A represent 2000 lb. of weight resting on the grade BC. Let CD be vertical, BD being the horizontal earth surface. Draw AF also vertical and of a convenient length to represent the 2000 lb. of weight acted upon by gravity. Then, on the theory of the parallelogram of forces, which in this case will be a rectangle, let HA be drawn at right angles to BC. AE will then represent in direction and length the amount of resistance necessary, friction not being considered, to prevent the motion of A down the grade, and HA in direction and length will be the pressure of A upon the grade surface. The two triangles FAE and BCD will be similar, by reason of the fact that each of them have a right angle and also one of their other angles equal, viz., the angle at C and the angle at A as indicated on the diagram.

We therefore have the proportion:

$$AE : CD :: AF : BC$$

$$\text{Therefore } AE \times BC = CD \times AF$$

$$AE = AF \times \frac{CD}{BC}$$

But AE equals the pounds of resistance per ton. AF equals 2000 lb., and $CD \div BC$ is the grade per cent. That is to say the weight of 2000 lb. multiplied by the percentage of grade gives the length of the line AE, or in other words, the resistance in pounds necessary to prevent motion down grade.

In passing it may be noted that the length of the line HA added to the line AE makes it evident that between them they account for much more than the 2000 lb. But the fact that $H - A$ is shorter than $A - F$ indicates that the body if in motion does not rest on the incline with its full weight of 2000 lb. This will be the more evident as the slope approaches the perpendicular, the weight on the slope reaching its vanishing point when the slope has become quite up and down.

Incidentally it may be remarked that a 2000-lb. ton lends itself very conveniently for grade calculations, which thereby run 20 lb. to each per cent of grade.

Grade Measured Up the Slope

It is also to be noticed that grade is not measured along the horizontal but up the slope. This is convenient for outdoor purposes but not quite so convenient in consulting contour maps although, for grades used in road work, the difference between the two measurements is comparatively slight.

Closely related to the resistance necessary to prevent motion down the grade is the acceleration which grade produces where the resistance is not met. The word "acceleration" has begun to appear quite frequently in car advertisements and is sometimes used rather vaguely. It is, however, evidently a word to which the public is expected to attach some meaning.

In this connection it will be necessary to recall certain physical facts, which are that, omitting air resistance which does not greatly affect the acceleration at low speed, it is approximately accurate to say that a body dropped from rest will have fallen at the end of 1 sec. 16 ft., but its acquired speed at the end of the next second will be at the rate of 32 ft. per second. This is called its acceleration. If it continues to fall and the air resistance is eliminated, its speed at the end of each successive second would be 32 ft. greater than at the end of the preceding second, while its actual travel will have been at a mean speed equal to the speed at the beginning of the period plus the speed at the end of the period, divided by two, viz.,

Speed at beginning of second period, 32 ft. per second
Speed at end of second period, *i.e.*
$32 + 32$ 64 ft. per second
$32 + 64 = 96 \div 2 = 48$, or mean speed and drop of second period.

The total drop for the 2 sec. would be the mean speed of the first second, viz., 16, plus the mean speed of the second second, viz., 48, a total of 64 ft.

At the end of the third second, the speed would be, as above indicated, *i.e.*

Speed at beginning of third period, 64 ft. per second
Speed at end of third period, *i.e.*
$64 + 32$ 96 ft. per second
$64 + 96 = 160 \div 2 = 80$, or mean speed and drop of third period.

The total drop for the three periods or seconds would be the total of the drop for the first 2 sec., 64 ft., plus the mean speed of the third second, 80 ft., a total drop of 144 ft. for the 3 sec.

If the number of seconds which the body falls is successive, 1, 2, 3, 4 and 5, the increased spaces during each interval will be as 1, 3, 5, 7, 9, respectively, and the total space passed through will be as the square of the number of seconds, viz., 1, 4, 9, 16, 25. If these spaces and the total distance are multipled by 16, the results will be the distances in feet.

The rule is equally true with regard to fractions of a second. If a body starts from rest, in a quarter of a second it will have a speed of 8 ft. per second with a mean speed of 4 ft. per second, and as the interval is but ¼ sec., its actual drop will have been 1 ft. At the end of ½ sec. it will have dropped 3 additional feet, and at the end of ¾ sec. 5 additional feet, and between ¾ sec. and the full second, 7 ft. to a total drop of 16 ft.

It is also a fact that eliminating the question of friction, a body descending a slope will at the foot of it have acquired the same speed as if it had dropped perpendicularly to the lower level. Of course it does not arrive at that point on the slope in the same number of seconds.

Referring again to Fig. 2, if $B - C$ is assumed to be a 5-per-cent grade, it will of course be twenty times longer than the perpendicular $C - D$. Assuming for convenience that $C - D$ is 16 ft. in length, then $B - C$ will be twenty times 16 ft. in length. As in the case of a falling body, the average speed of the body on the grade will be one-half of the acquired speed, and as we have assumed $C - D$ to equal 16 ft., the speed will be at the foot of the grade the rate of 32 ft. per second and the average speed at the rate of 16 ft. per second. In other words, it will have taken 20 sec. to have descended from C to B, and its total acceleration being 32 ft., its acceleration per second for each second of its journey will be 1.6 ft. In other words, the acceleration on the grade per second will be found by taking that percentage of 32 ft. which shall be the grade percentage.

Calculation Is Simple

We have, therefore, three expressions relating to grade which are in a sense interchangeable, and any one of them being given, the other two can be calculated easily. If we multiply 32 by the grade percentage we get the acceleration in feet per second. If we multiply 2000 lb. of resistance by the grade per cent, we get the resistance per ton for that grade. And conversely, if we know the resistance per ton, dividing it by twenty will give us the grade per cent, expressed as a whole number instead of a decimal. (Dividing by 2000 will produce the decimal grade, 0.03, or 0.05, or 0.07, which is read 3 or 5 or 7 per cent as the case may be.) If on the other hand one has the figures 1.6 acceleration, dividing by 32 will give the grade per cent.

Or by multiplying by 62.5 the corresponding resistance in pounds per ton will be found. The whole operation in this case is the division of the acceleration by 32, which has the effect of producing the grade per cent, and multiplying that by 2000. The equation then stands:

$$R = \frac{1.6 \times 2000}{32}$$

Cancelling out the 32 against the 2000 produces the 62.5,

Plan view of the Ross eight chassis for 1917, which has a 130-in. wheelbase and uses 34 by 4 tires

Better Body Lines in Ross Eight

1917 Model Shows Practically No Mechanical Changes —Double Cowl a Feature—Chassis Is Strongly Built

FOR 1917, the Ross eight-cylinder car appears in a new dress that is in accord with latest body fashions in every particular. The vehicle is practically the same mechanically as it was when this model was first brought out by the Ross Automobile Co., Detroit, over a year ago, but there have been some important revisions of its lines that make it a very attractive car. However, the price remains unchanged at $1,350.

Equipped with a standard eight-cylinder Herschell-Spillman engine with dimensions of 3¼ by 5 in., it has ample power under all conditions, and, although it is a big car with a wheelbase of 130 in., it is lively and responds readily to the throttle. Ross has taken care of the suspension so that riding is in comfort whether the full quota of seven passengers is being carried or only one or two.

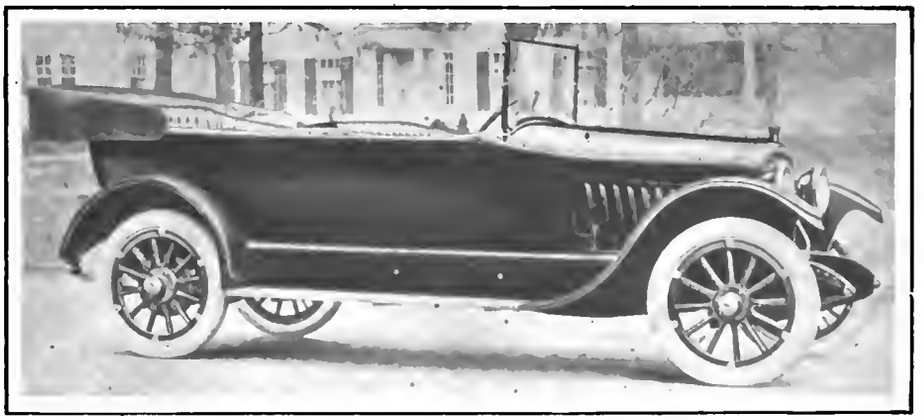
The modern double-cowl effect has been worked out at the back of the front seat, and the hood slopes into the cowl without a break, the radiator shell also sloping to the hood in a very pleasing manner. Doors are wide and fit snugly, and there is enough rake to the steering column to assist in giving the racy appearance so often sought by designers but sometimes not attained.

Stripped of its new body, the chassis presents a most substantial look, with a tapered frame of deep section, sturdy drive members and long and wide springs. In unit with the motor are the clutch and gearset, and the driveshaft is inclosed within an efficient torsion tube. The specifications include a multiple-disk clutch, floating rear axle, semi-elliptic springs all around, rear gasoline tank with Stewart vacuum feed, Zenith carbureter, Ward Leonard two-unit starting and lighting system and 34 by 4 tires.

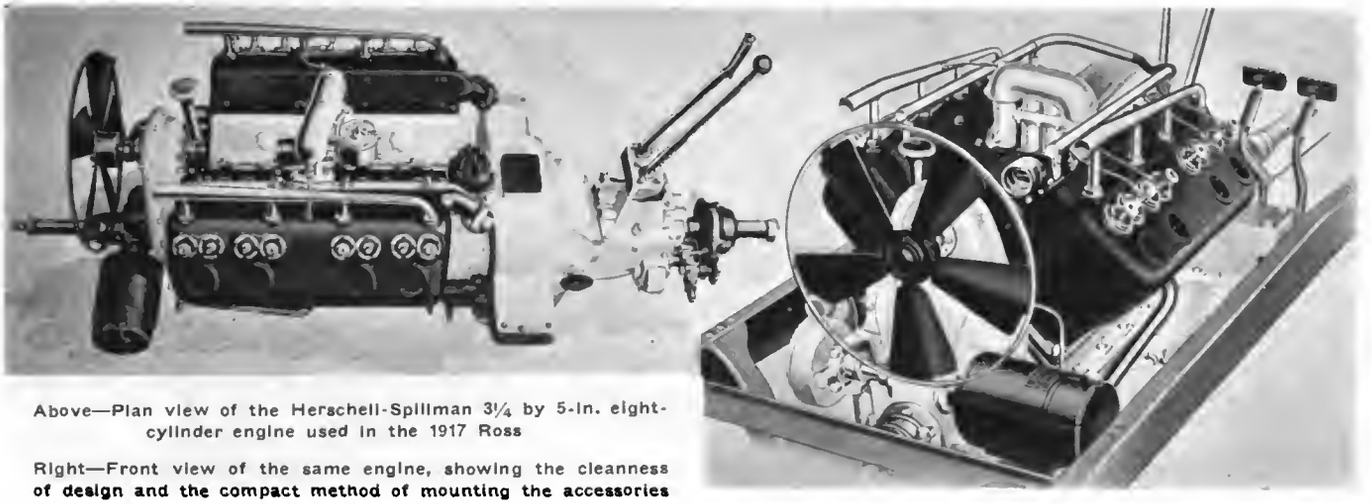
Turning to the most important unit, the engine, it is at once noted that no alteration has been made in the standard Herschell-Spillman design. The cylinder dimensions give a rated power of 33.84 hp., with a displacement of 331.8 cu. in., but the motor is capable of delivering upward of 75 hp. on the block, an evidence of the fact that there is plenty of power under the Ross hood to take care of the car under all conditions.

Inasmuch as this engine has been described on several occasions, it is not necessary to go into very great detail. The photographs indicate the general arrangement, with the two blocks of cylinders at 90 deg. and staggered to allow the two opposite connecting-rods to be mounted side-by-side on the common crank bearing. The valves are made reasonably accessible by the disposition of the parts that of necessity have to be in the V between the cylinder blocks, the carbureter being so mounted that it is little in the way, and the exhaust manifolds being well above the valve compartments. Although the ignition distributer is mounted vertically at the extreme rear of the cylinders, it is really not in the V, and so the carbureter is practically the only obstruction.

Conventional practice holds throughout the internal construction of the motor, there being a sturdy crankshaft, directly above which is mounted the single camshaft that actuates both sets of valves through rockers that are hinged to the top of the crankcase. At the front there is a cross shaft that is connected to the crankshaft by a worm gear and on



The Ross eight-cylinder seven-passenger touring car for 1917 which sells for $1,350



Above—Plan view of the Herschell-Spillman 3¼ by 5-in. eight-cylinder engine used in the 1917 Ross

Right—Front view of the same engine, showing the cleanness of design and the compact method of mounting the accessories

its right end this shaft drives the double water pump, while the left end connects to the generator armature. This cross shaft drive is inclosed by the same plate that houses the spiral gears, driving the camshaft and the fan shaft above this latter. Thus a very compact front end is obtained with not even an exposed fan drive. The drive of the vertical ignition distributer is through bevel connection with the camshaft at its rear end.

On the right rear side of the engine is carried the starting motor, this connecting automatically with the flywheel teeth by means of the Bendix drive unit, whereby, when the current is switched to the starting motor through the starter pedal, the rotating of the armature shaft automatically throws the pinion gear into mesh with the flywheel. After the engine picks up and rotates faster than the armature shaft, the pinion is again automatically thrown out of mesh.

No Exposed Mechanism

As the flywheel is inclosed, there is practically no exposed operating mechanism in this power plant, a feature that is commendable from a mechanical and maintenance standpoint, although it adds slightly to the weight.

Lubrication is given special attention, as it is an important part of the proper operation of an eight. There is no splash to it; distribution to the various bearing surfaces is entirely by pressure maintained by a regulating valve between a minimum of 10 lb. per sq. in. and a maximum of 40 lb. per sq. in. The gear pump is located in the crankcase well on the bottom of a vertical shaft which takes its drive through spiral gear connection with the camshaft. Oil is delivered through a longitudinal tunnel running the length of the crankcase, and from this by individual branches to the three main bearings of the crankshaft and the three camshaft bearings. The crank webs are drilled, and the oil is thus led by centrifugal force to the lower rod bearings, from which it is piped through steel tubes to the wristpin bearings, these tubes attached to the rods. An overflow valve allows the excess over the requirements of these bearing surfaces to be delivered to the front gears, keeping the gear assembly submerged well above the cross shaft.

Ross is using the Borg & Beck clutch, which is the type in which there is only one plate, this running dry between two wire-woven asbestos plates, and by a series of levers the force holding the plate in engagement is stepped up to a very large amount without the use of an extraordinarily heavy spring. A 200-lb. spring is sufficient to produce a pressure of 2500 lb. at the point of plate engagement, due to the construction. This therefore prevents any clutch slippage, and at the same time the unit is easy to operate, requiring only a light pressure on the clutch pedal to disengage it. In connection with the clutch mechanism, the pedal is adjustable for position, due to the use of a flange drilled with several holes and attaching to a flange on the pedal in a number of different positions wherever any set of holes in the two flanges will register.

A Grant-Lees gearset is also incorporated with the engine, this being a very compact unit affording the usual three speeds and reverse. The gears and shafts in this unit are constructed of chrome-nickel steel, and the gears have wide faces with stubby teeth for strength. Just back of the gearcase is the speedometer drive gearing, and then a universal joint, after which the propeller shaft enters a torsion tube that is in unit with the rear axle. The front end of the tube is supported in and slides in an arm that hinges to the bottom of the gearbox.

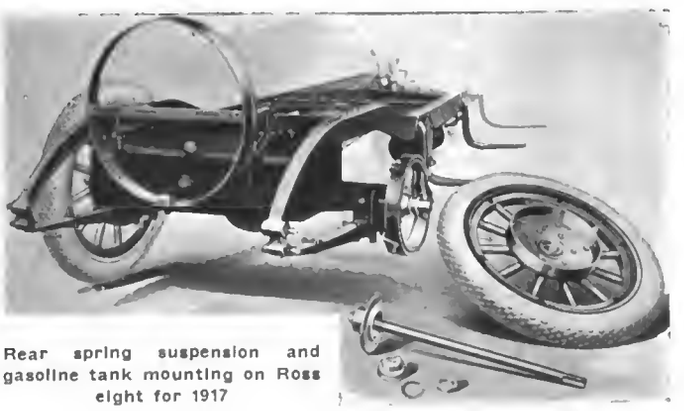
Rear Springs Slung Under Axle

Both axles are manufactured by the American Gear Co., and follow standard lines. The rear unit has a pressed-steel housing that is webbed outside at top and bottom as a strengthening factor, and the springs are underslung from it. The gear ratio is slightly lower than 4 to 1 in order to give the engine plenty of consideration. This ratio is such that the car affords excellent accelerative possibilities.

Now quite familiar is the semi-elliptic form of spring suspension at the rear. In the Ross adaptation, the springs have a length of 57 in., and due to the generous bend down of the rear of the frame, they are normally nearly flat, even though they do pass below the axle. This allows them to work efficiently to dampen road shacks and to promote easy riding as well as being better for them.

Hung from the rear cross member of the frame is a large gasoline tank, so positioned that it is practically balanced on its mounting, preventing any bending strains being set up.

Nothing has been forgotten in the equipment of the new Ross, the list of articles including a motor-driven horn, one-man top, Stewart speedometer, ammeter, demountable rims and the usual complement of tools.



Rear spring suspension and gasoline tank mounting on Ross eight for 1917

Chassis of the Jeffery Roll-Edge Four for 1917, showing the mounting of the 3¾ by 5¼ block engine, three-speed selective gearset, etc. It is stated that 93 per cent of the parts used in this car are manufactured in the Jeffery plant

New Body Feature of Jeffery Four

No Chassis Changes in 1917 Model Which Is Called Roll-Edge Four—Price $95 Higher—Body Lines Unbroken from Front to Rear — New Cellular Radiator Used

FOR 1917 the Jeffery four is continued with no changes in the chassis, a price increase of $95, the new car selling for $1,095, and a new body which gives the car the trade name of the Roll-Edge Four. A new cellular radiator is the only other change.

Body Lines Unbroken

The roll-edge four comes upon the demand of Jeffery dealers who have been insistent since the six was announced last January with a roll-edge body, that the four be furnished them in the same style, according to the announcement of the factory.

A particularly noteworthy feature of this new Jeffery body is its unbroken lines from the radiator to the rear seat and between fenders. The roll edge on the top of the body blends into the hood without any break whatever from the straight line effect, making the car look exceptionally long and clean. The divided front seat feature which was a part of the 1916 body design is continued without change.

93 per Cent of Car Jeffery-Built

The new four has a 3¾ by 5¼ in. block engine, disk clutch, three-speed gearset, and semi-floating axle. The wheelbase is 116 in. and the tires are 34 by 4. Practically every part of the car is Jeffery built, in fact the manufacturers state that 93 per cent of the machine is constructed in the Jeffery factories.

Comfort an Important Consideration

The new bodies are finished in Savoy green with a fine gold stripe, fenders and running gear black, and the wheels green with a gold line. Upholstery is in black leather with deep double-deck springs. Auxiliary seats which disappear in the back of the front seats are standard equipment on all models. Inasmuch as the rear seat is 48½ in. wide the car provides for seven passengers very comfortably.

Side view of the Jeffery Roll-Edge Four for 1917, showing the unbroken body lines and the feature which gives the car its name. Wheelbase is 116 in. and tires are 34 by 4. The car sells for $1,095 with complete equipment

Rate Tractors by Drawbar

Present Horsepower Rating Misleading to Farmers—Rating Should be U. S. Standard

By Raymond Olney*

ONE of the greatest needs in one of the greatest fields in agricultural engineering is that of a standard basis for rating farm tractors.

The present method, which any engineer must admit is unsuited to the purpose, is to rate the drawbar capacity of a tractor at about one-half the brake or belt-power rating of the engine. This is a relic of the early days of the gas tractor industry. But worse than that, it gives the farm buyer no definite idea as to the actual pulling capacity of a tractor. Such a method is not only unsatisfactory; it is misleading.

The engine rating should be in terms of horsepower; I believe all engineers are agreed on that point. But the drawbar rating is another matter.

The term "horsepower" is one that is easily misunderstood by the average farmer, especially so when it is applied to drawbar power. His knowledge of mechanics being limited, he ordinarily thinks of a tractor rated at so many drawbar horsepower as the equal in pulling ability of that number of horses, which, of course, is not true.

In his experiments on the draft of horses, F. H. King found that about the maximum walking draft of a horse is one-half its own weight; and pulling with this intensity at a speed of 2½ m.p.h., the power developed by a 1200-lb. horse would be 4 mechanical horsepower. For steady and continuous work 10 hr. a day, at the same speed, it is commonly allowed that the horse should not be called upon to pull more than one-tenth his own weight; at this rate a 1200-lb. horse would develop 4/5 hp. The average farm horse, particularly for heavy work, will not travel as fast as 2½ m.p.h., and will probably develop at the slower speed an average of not more than 2/3 hp.

Why Rating Is Misleading

Assuming a 25 per cent overload, your tractor capable of 12 drawbar horsepower will develop 15 hp. as its maximum load. On the basis of a maximum walking draft, as recorded by King, a four-horse team will also develop 15 hp., but only for short distances, of course. Now if a farmer gets a 12-hp. tractor into a tight place and finds that it will then pull no more than a four-horse team, he is quite apt to wonder what is wrong, and the cause of his wonder is the confusion resulting from our method of rating.

This is not the most important reason, however, why the rating should not be given in terms of horsepower.

Suppose the man who wants a tractor visits one of our public power-farming demonstrations, where he sees machines of nearly every make and size demonstrating their ability to pull plows. Here we will say he finds three different tractors, each pulling a gang of four plows, which we will assume is the normal full-load capacity of each. One may be rated at 12 hp., another at 15 hp., and another at 18 hp., but each pulling the same number of bottoms. This is no puzzle to the engineer, but it is to the farmer; it is decidedly confusing to him, because he is not familiar with the relation of speed to power.

Again he may see two tractors plowing within a few yards of each other, each with a drawbar rating of 12 hp., but one pulling three plows and the other four. In this case, as in the former, the engineer would readily appreciate that the factor of tractive speed accounts for these differences, but the farmer might not.

The greatest objection, as I see it, to the present method of rating is that it gives the prospective purchaser no understandable means of comparing at once the actual pulling ability of the different makes and sizes of tractors.

There is a tendency at the present time to rate the pulling capacity of tractors according to the number of plows they will haul under average soil conditions, say, a two, three or four-plow machine. But this method is equally as unsatisfactory as the one now in use, for the reason that the terms "average soil conditions" means something different for different kinds of soil. The draft of plows not only varies widely in different kinds of soil but in the same soils under different conditions.

I am convinced that the only logical method of rating the pulling ability of tractors is in pounds. Tractor engineers have already discussed this subject to some extent and this method seems to be gaining some support. A tractor concern which has taken the lead in this direction, makes the following statement in its catalog as to why it favors a pounds-pull rating:

"We rate the power of our tractors in actual pounds pull developed at the drawbar, because the wide difference in ratings of identical size motors given by various manufacturers, and the variation of mechanical efficiency of different tractors, makes a horsepower rating of little real value to the purchaser in determining just what any tractor with merely a horsepower rating will pull."

I will show graphically why it is more logical, as well as scientific, to rate the pulling capacity of a tractor in pounds pull instead of in terms of horsepower. The two sets of curves shown illustrate my contention very clearly. The curves of "engine torque" and "brake horsepower" were reproduced from the data obtained from an actual Prony brake test on a 3½ by 5¼ tractor engine of the four-cylinder, heavy-duty type.

Two facts of prime importance are brought out by the curves: 1—The torque is practically constant throughout a wide range of engine speeds; this is characteristic of gas

TABLE OF ENGINE AND TRACTOR DATA

R. P. M	Brake H. P.	Torque In.-Lb.	Drawbar Pull-Lb.	Drawbar H. P.	Speed M. P. H
400	8	1260	2010	535	1
600	13	1370	2250	900	1½

Size of Engine—3½ x 5¼; gear ratio, 84 to 1; transmission efficiency, 85 per cent.; rolling resistance, 16 per cent.; drive wheel diameter, 70½ in.; weight of tractor, 4500 lb.

*Paper read at N. G. E. A. convention in Chicago, June, 1916.

power motors; 2—The brake horsepower varies directly as the speed up to a certain point.

For the purpose of illustration I will suppose that this engine is installed in a tractor, for which I will assume a gear ratio of 84 to 1, a transmission efficiency of 85 per cent, a drivewheel diameter of 70½ in., and a total weight of 4500 lb. My object is to calculate the drawbar pull.

The torque of the engine and the gear ratio determine the pulling ability of a tractor. The pounds pull at the drawbar is the product of the engine torque, gear ratio and transmission efficiency divided by the radius of the drivewheel, less the tractive resistance, which I will assume is 15 per cent in this case. This gives me the column "drawbar pull" (in the table), and from this is plotted the curve of "drawbar pull," which, of course, is similar to the torque curve since drawbar pull varies directly as the torque of the engine.

The drawbar horsepower is the product of the pounds pull and the tractive speed divided by a constant, and varies directly as the speed.

By referring to the "drawbar horsepower" curve, it is evident at once that we might give our tractor a drawbar rating of from 8 to 20 hp., depending upon the speed of the motor and assuming that the gear ratio remains unchanged. And herein lies the chief objection to a rating in terms of horsepower.

On the other hand, the engine torque, and likewise the pounds drawbar pull, remain practically constant throughout a wide range of speed, so long as the gear ratio does not change. Between a motor speed of 800 and 1400 r.p.m., or a corresponding tractive speed of 2 and 3½ m.p.h., as shown by both curves and table, the pounds pull at the drawbar is practically constant. Also between tractive speeds of 1¾ and 4 m.p.h., which represents the extreme limits of working speeds of tractors, the variation in pounds pull at the drawbar is exceedingly small.

The farmer is not so much interested in the amount of horsepower that a tractor is supposed to develop at the drawbar; he is more concerned with the actual pulling force it is capable of exerting on a plow or other implement. If the drawbar rating of your machine is in pounds pull, you are giving him something tangible, and throughout a fairly wide range of engine speeds this pull will remain practically constant. There is no confusion in his mind as to the tractor's actual drawbar capacity.

In case this method of rating is adopted as standard, as no doubt it will be sooner or later, it will be essential to have the tests on which the different ratings are based carried on under some sort of official supervision. Equipped as it is with its fine corps of trained experts and the excellent facilities at its disposal, it is a wonder to me that the United States Department of Agriculture did not long ago see the vital need of a standard rating for farm tractors, to the extent of taking some action in this direction. It is only within the past few months that the department seems to have taken the problem seriously.

In the first place, provided the manufacturers adopt the plan that is being worked out, it is my opinion that the U. S. D. A rating should include an engine as well as a drawbar rating. A Prony brake test should be made to obtain data for determining the torque and brake horsepower at various speeds. The torque curve of any engine, like the one shown here, will indicate the normal or critical speed, or the speed at which the engine produces the greatest torque. The brake horsepower rating should be given on the basis of the torque at this speed.

The basis for the drawbar rating should be the pounds pull exerted in an actual pulling test. The drawbar test should be made with the engine running at its critical speed and with the tractor traveling at its best working speed as fixed by the gear ratio.

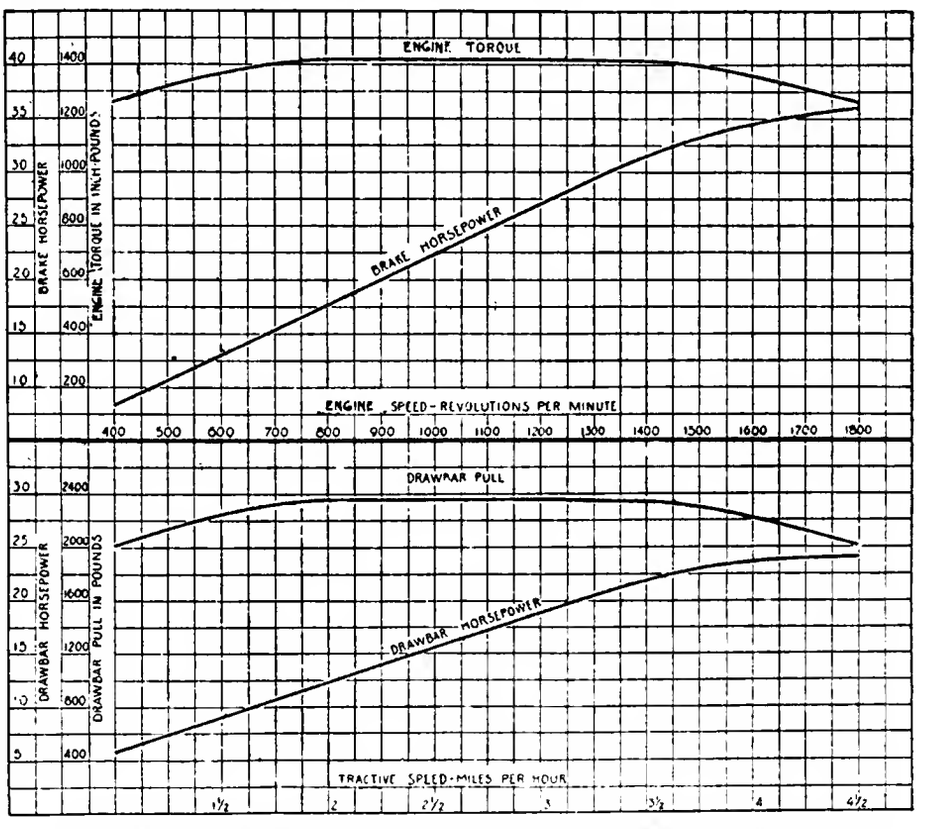
Just what equipment, conditions, etc., should be standardized for conducting such tests is a big problem in itself and I will touch on it only briefly.

Personally, I am of the opinion that, for all practical purposes, it would be sufficient to have tests for establishing drawbar ratings made on hard, level ground, such as a good, dragged dirt road, where slippage for most tractors would be practically negligible. The necessary data could be obtained by means of a recording traction dynamometer such as the one developed and perfected by the Hyatt Roller Bearing Co., with which the majority of tractor manufacturers are already familiar.

Draft Tests on Dirt Road Easiest

While draft tests conducted on a dirt road would show a higher drawbar pull than a tractor would be capable of delivering in a sod, stubble or plowed field, it would be a much less difficult problem to secure standard conditions of footing there than in a field where ground conditions may be extremely variable.

A method of indicating a tractor's rating, that has already been suggested, is by means of a double figure, as is the present practice, but to use pounds pull instead of the drawbar horsepower; as 1500-20 instead of 10-20, or 2000-25 in place of 12-25, the first figure in the combination representing the pounds pull and the second the brake horsepower. With this rating should also be included the tractive speed at which the machine will operate best under load.

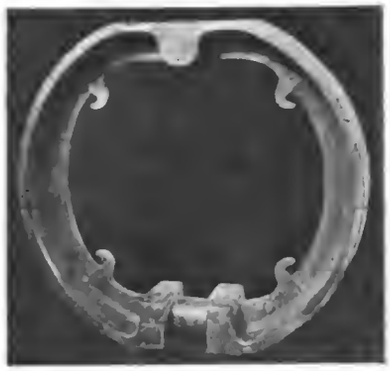


Curves based on results of Prony brake test of four-cylinder 3½ by 5¼-in. tractor engine, illustrating advantages of rating pulling capacity of tractors by pounds pull

Aluminum Engines Coming in France

Peugeot and Panhard Make Aluminum Engines Without Cylinder Liners — Aluminum Brake Shoes Popular

By W. F. Bradley



Aluminum brake shoes for Peugeot truck

THE general adoption of the aluminum piston, which has been such a remarkable feature of the American automobile industry, has had no counterpart in Europe. This is all the more surprising when it is remembered that the initial experimental work was done in France and Germany, and that the Cothias process of aluminum die casting—known in America as the Lynite—was extensively employed in France as far back as 1897 for a variety of small mechanical parts.

Six or seven years ago, when the question of motor efficiency was beginning to receive close attention, experiments were made with aluminum pistons by practically all European firms. At that time, however, certain details remained to be perfected and, after tests which were not completely satisfactory, the factories one by one decided that aluminum was not practicable for pistons. Where light reciprocating parts were required, steel pistons were used, and for racing purposes steel pistons machined from the solid billet were the invariable equipment. The only French firm having changed unhesitatingly for the aluminum piston is the Chenard & Walcker company, which has used it on all its stock motors for the last 4 or 5 years. The general public, however, is not aware of this fact; and so small is the amount of publicity concerning aluminum pistons that it probably would have done the firm more harm than good to state that they had departed from the ordinary methods.

Panhard & Levassor's Work

For the last two or three years the Panhard & Levassor company has made use of aluminum pistons on a little 10-12-hp. poppet valve model of 2¾ by 5½-in. bore and stroke. This is a very successful and very popular model, but even dealers generally are not aware that they have been selling a car with aluminum pistons.

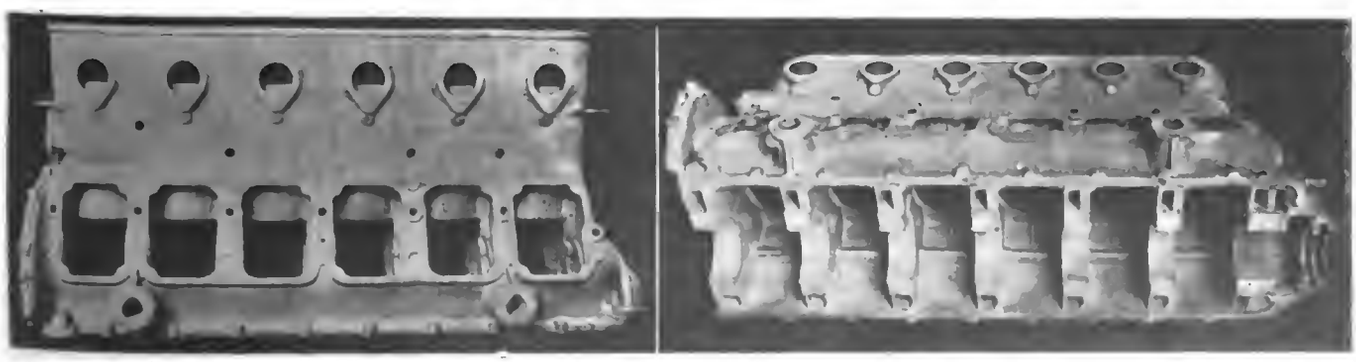
The D. F. P. company has made a practice of fitting its sporting models with aluminum alloy pistons, again without informing the public of this fact.

In Italy the general situation has been similar to that of France. All the Italian factories experimented with aluminum alloy pistons, but with the exception of the comparatively little-known Chiribiri company of Turin, not one firm adopted them for stock models. The Aquila-Italiana company did much experimenting, but does not appear to have been decided about the complete adoption of aluminum alloy pistons. The Fiat company, which maintains its own aluminum foundry, is also much interested in this question. It has used aluminum alloy pistons on its racing cars, particularly on the three machines which ran in the last French Grand Prix at Lyons. These cars had engine trouble, but the pistons stood up in a very satisfactory manner. Aluminum alloy pistons are also employed exclusively on Fiat aviation motors—and this firm is the biggest aviation motor producer in Italy. For stock models the firm appears to be hesitating. For some of the latest models experimental cars were given hard running on the road for a full year in order to get a definite opinion as to the value of aluminum, without, however, so far as can be learned, a decisive result being arrived at.

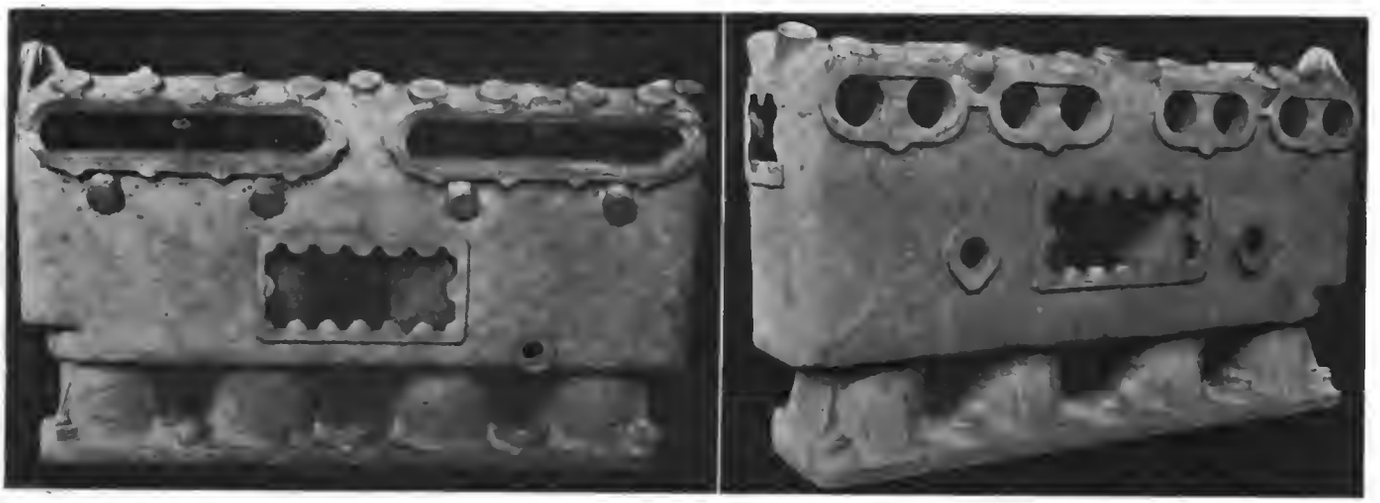
Steel Reigned for Years

No important European races have been won with aluminum pistons. Peugeot, who during the last 5 years has done more racing than any half dozen firms combined, has invariably employed steel pistons and been fully satisfied with them. The same applies to Delage. Sunbeam, until quite recently, has been satisfied with steel pistons machined out of the solid. At the annual Monaco motor boat races, where much experimental work was seen, the steel piston was supreme.

Since the outbreak of the war, with the requirement of large numbers of high-efficiency aviation motors, manufacturers have been led to reconsider the claims of aluminum pistons and in many cases have taken up the type of piston



Left—Exhaust side of Panhard & Levassor sleeve-valve motor with cylinders and crankcase cast in aluminum alloy. Right—Interior view of Panhard & Levassor sleeve-valve motor with 5¼-in. bore. Cylinders and crankcase are cast in aluminum alloy by the Cothias method. This process has been used in France for casting numerous small aluminum mechanical parts since 1897



Left—Intake side of Peugeot four-cylinder, sixteen-valve racing type motor cast in aluminum alloy. Cylinder liners and separate valve seats are still to be installed. Right—Exhaust side of Peugeot racing motor casting

they cast aside 6 or 7 years ago. Quite recently the Le Rhone aviation engine company—now combined with the Gnome—produced a new engine from which 120 hp. was obtained. The result was not considered satisfactory and the cast-iron pistons were changed for Cothias die-cast aluminum alloy pistons, when the power was increased to 150 hp., no other changes being made.

As a result, the whole of this series will have aluminum alloy pistons and many of the Gnome engines, with steel cylinders, will also be fitted in the same way.

The Lorraine-Dietrich Co. has had a similar experience. After using cast-iron pistons in an eight steel cylinder water-cooled aviation engine, they got better results with aluminum and completely adopted Cothias die-cast pistons. These pistons are deeply ribbed from the head to the skirt. The Cothias pistons are known in America as Lynite, the Cothias rights having been acquired by the Aluminum Castings Co. of Cleveland.

Peugeot and Hispano-Suiza Interested

Among other firms now making use of aluminum alloy pistons, either completely or partially, are Peugeot and Hispano-Suiza. It is certain that the outcome of present aviation experience will be an extensive adoption of aluminum pistons for car motors. Not a few firms have been experimenting in this direction while the war is in progress, but without making known their results. It is certain, however, that firms will not be rushed into the adoption of aluminum alloy pistons. One factory ran a set of pistons 60,000 miles without dismounting before being convinced. Another put three cars on the road and ran them 12 hr. a day for a full year in order to be sure that the change from iron to aluminum was a wise policy.

Aluminum cylinders also have come to the front during the war period. There is no stock car on the European market fitted with aluminum alloy cylinders, but it would appear that the first commercial adoption of this type of cylinder was made by the Hispano-Suiza Co. of Paris and Barcelona. Engineer Birkigt, of this company, 2 years ago produced an eight-cylinder V engine with each set of four cylinders forming a single aluminum alloy casting, into which thin steel liners were screwed. The head was detachable and of cast iron, and it carried the vertical valves operated by an overhead camshaft. Several patents have been obtained covering the methods of constructing this motor, particularly the system of screwing the liners into the aluminum cylinders and the valve-operating mechanism. The aluminum cylinders are enameled inside and out to guard against any possible porosity of the metal, and the final finish of the outside of the cylinder is a fine black enamel. This motor has been produced in series for a full year and has been most successful. Before its construction was decided on in big quantities it went through 50 hr. full load official brake test. The weight of this motor is 2.4 lb. per hp. without water or oil. Its consumption of gasoline and lubricating oil is very moderate.

The Panhard & Levassor Co. has been running an aluminum cylinder engine, driving factory machinery, for 22½ hr. a day, 7 days a week, for a full year. This engine has no cylinder liners, but the valve seats and head are of cast iron. Although this motor ran constantly for 365 consecutive days, with the exception of the 1½ hr. each day the factory was shut down for meals, no troubles have developed.

The same firm has had on the road during the past year a number of cars with Knight engines, 4⅛ by 5½-in. bore and stroke, fitted with aluminum alloy cylinders without liners. These cylinder castings weigh 46 lb., but in iron the weight is 115 lb. One of the most interesting examples is a big six-cylinder block Knight engine with cylinders and upper half of crankcase forming one casting of aluminum alloy. This with a bore of approximately 5¼ in., has sleeves operating direct on the aluminum walls, and weighs only 202 lb. rough from the foundry. Completely machined, the weight is reduced to 145 lb. A similar casting in iron weighs 510 lb., rough from the foundry, and 375 lb. completely machined. Several of these big motors are in service, with good results so far.

The Peugeot Racing Motor

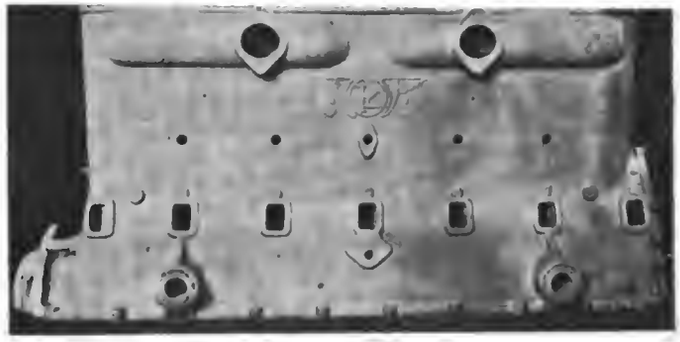
Another important aluminum cylinder engine is a four-cylinder, sixteen-valve Peugeot racing type, shown in one of the illustrations. This has neither cylinder liners nor separate valve seats. In its general design it is exactly similar to the racing engines used by Peugeot on the 1914 Grand Prix cars now in America. The casting shown in the illustration weighs 63 lb. in the rough—that is, before any machining has been done. The cylinders are approximately 2.7-in. bore. The same rough casting in iron weighs 170 lb. On an eight-cylinder engine there is a saving of about 200 lb. by the use of aluminum alloy in place of cast-iron cylinders. These engines are a high-efficiency type running normally at 2800 r.p.m. and several of them are in service.

Another aluminum cylinder engine is a twelve-cylinder horizontal with cylinders cast in groups of six, pistons and valves operating direct on the aluminum. Another make is a six-cylinder vertical with superimposed valves in the head, also without cylinder liners or separate valve seats. It is obvious that the use of aluminum cylinders for cylinder castings is of the greatest importance to aviation engine manufacturers. By this means only has it been possible to get the

weight of fixed cylinder engines down to the low figure of such engines as the Gnome, which are practically all steel, machined out of the solid. The V-type aluminum cylinder costs considerably less to produce than the rotary Gnome type, and is much easier to assemble and keep in condition; while the two types are about equal in weight on the scales, the V engine has a decided advantage when account is taken of gasoline and oil required for a long period of running.

European firms are studying after-the-war models while fighting is in progress. It is too early to say what these models will be like, but it is practically certain that aluminum alloy will replace cast iron for the cylinders of the bigger touring car engines. What may be expected is the appearance first of Knight engines with aluminum alloy cylinders, followed later by poppet valve engines in the same metal.

A development which does not appear to have received the same amount of attention in America as in Europe is the use of aluminum for brake shoes. These are very common on both trucks and touring cars made by the leading French makers. With the tendency toward unit construction of engine and gearbox, both brakes have to go on the rear wheels. European ideas will not admit of internal and external brakes on even the cheaper classes of car, thus the shoes are placed side by side within big diameter drums. Here the use of aluminum enables an appreciable saving of weight to be effected. Panhard-Levassor cars are a good example of this; the rear axle of all this firm's models has an aluminum differential housing, and the big diameter brake shoes are aluminum die castings. Peugeot is another firm making use of aluminum shoes on both touring cars and trucks. Naturally these shoes are lined with asbestos fabric or similar material.



Panhard & Levassor Knight type motor of about 5¼-in. bore with cylinders and crankcase in aluminum alloy

Simple Tests Show Car Condition

(*Continued from page* 8)

which is conveniently known as a constant of gravitation.

If one has found by experiment the resistance at a given speed, and thereafter by a second experiment has found the acceleration in feet per second, he is enabled to find the point on the torque curve at the speed mentioned by multiplying the acceleration in feet per second by the constant 62.5, which gives him the additional capacity of the engine necessary to overcome resistance in pounds per ton, which result is added to the known pounds of coasting resistance, the total indicating the proper location of the torque curve point.

Referring again to Fig. 1, it is evident that if a car is running on the level and at a speed which shows the resistance curve considerably below the torque curve, the opening of the throttle will produce acceleration and the opening of it wide will produce the energy necessary to overcome the number of pounds of resistance per ton which are measured between the coasting resistance curve and the torque curve. It should be remembered, however, that at once the speed of the car will begin to increase and immediately the acceleration will fall off. Otherwise, the speed increases indefinitely.

This does not, however, interfere with the accuracy of the acceleration indication because the definition of acceleration does not require that the force should act through a complete second, but merely that when the force begins to act it shall have the capacity indicated if its action continues through a complete second.

In several of Professor Marshall's diagrams the difference was made evident, by means of curves, between cutting off the ignition, declutching, and bringing the gearshift into neutral, these three being the three ways of cutting off the engine power and coasting.

The usual effect, as shown by him and illustrated by the curves plotted from experiments, showed that the least resistance to coasting was produced when the engine was left running and the gear shifted to neutral, the explanation of this being that the running of the engine took care of the friction in the jackshaft which otherwise had to be absorbed in the coasting resistance, and of course the greatest resistance to coasting was produced by merely cutting off the ignition, for in that case the resistance of the engine, both by compression and friction, had to be overcome in addition to the ordinary resistances.

The distance between each of these curves, measured on the upright lines showing pounds of resistance, indicated the engine friction in one case and the friction in the jackshaft in the other case.

For most purposes there would seem to be no necessity for converting resistance and speed into horsepower, but Professor Marshall exhibited a number of figures showing horsepower, comparing several cars with each other.

The horsepower formula assumes the value of 33,000 lb. lifted 1 ft. in 1 min. as the unit of horsepower. A car traveling 1 m.p.h. covers 88 ft. in 1 min., and 88 ft. divided into 33,000 lb. gives as a quotient 375. The utilized horsepower of any given car then is equal to resistance in pounds per ton, multiplied by the number of tons weight of car and passengers, multiplied by the number of miles per hour and the whole divided by 375. It will be seen, therefore, that, by taking the necessary time for the calculation, a diagram may be produced in which instead of resistance in pounds per ton, the horizontal lines shall represent either horsepower capacity or horsepower expended. The horsepower so exhibited would be the brake horsepower. It is, however, usual, as Professor Marshall points out, to consider that there is a loss at the rim of some 23 per cent of horsepower generated by the engine, so that, having determined the actual brake horsepower by plotting the curve which shall show 23 per cent additional horsepower, one will arrive at the horsepower delivered at the clutch.

The most obvious difference between a horsepower curve and a resistance curve is that the effect of multiplying resistance by speed, in producing the horsepower curve, is to cause the curve to sweep more rapidly upward so that in comparing the curves of two cars a difference which might seem slight in a resistance curve becomes more pronounced when the horsepower curves are examined.

As a matter of general interest, it may be mentioned that a car coasting down a given grade will, if permitted, reach a maximum speed which it will not exceed, that speed being the point where the coasting resistance curve intersects the resistance due to grade. For example, a 5-per-cent grade corresponds to 100 lb. of resistance. If the coasting curve indicates a resistance of 100 lb. at 20 m.p.h., the car cannot exceed 20 miles on that grade.

Wisconsin Adds Aviation Engine

Aluminum Cylinders With Hardened Steel Liners—Many Features Like Racing Engine—Detail Highly Ingenious

IN designing their aviation engine the Wisconsin Motor Mfg. Co. of Milwaukee, Wis., have adhered very closely to the general principle of their racing automobile engines. That is to say, the overhead valves are operated by an overhead camshaft with rocker arms and many of the details are arranged the same way. The aviation motors, however, are much larger, having a bore of 5 in. and a stroke of 6½ in., they being intended for coupling direct to the propeller which mounts on the end of the crankshaft. There is still much argument among aeronautic engineers regarding the relative advantages and disadvantages of direct-driven and gear propellers. The Wisconsin company have chosen to make an engine developing maximum power at a moderate speed, believing that they can thereby obtain the greatest dependability. At present two models are being made, one with six and the other with twelve cylinders, the dimensions being the same.

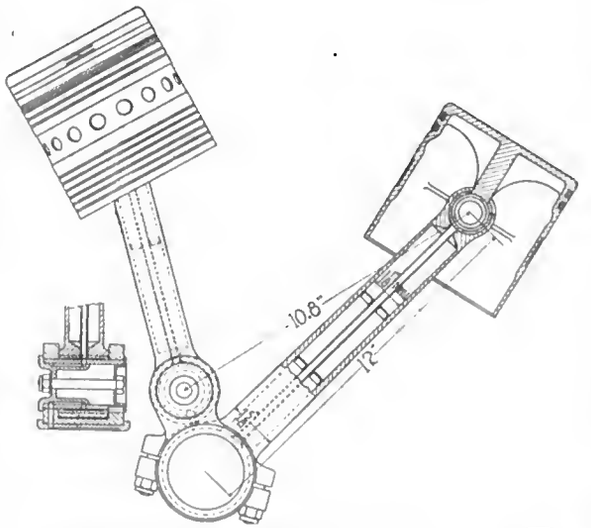
Aluminum Used Extensively

Aluminum enters very largely into the construction of these engines, the cylinder castings for which were illustrated in THE AUTOMOBILE last fall. For the valve seats cast-iron rings are machined and copper plated. They are then heated and placed in position on the core before the casting is made. Cylinders which have been cut up show that the copper makes an intimate connection between the aluminum and iron; in fact if the cylinder is cut in two across the diameter of the valve seat it is only possible to remove the half circle of iron by applying considerable force with a hammer.

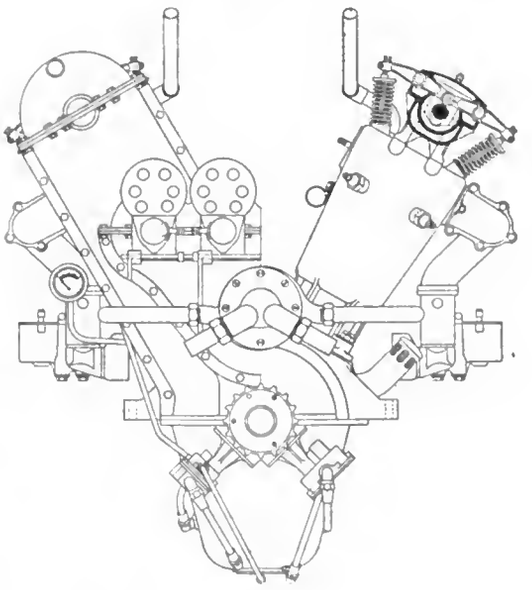
Instead of using cast-iron linings for the cylinders, hardened steel sleeves are employed, the pistons being made of the same grade of aluminum alloy as the cylinders. These pistons are typical examples of the aluminum type having substantial supporting ribs beneath the head. There is no wristpin bushing, the pin being fixed in the upper end of the connecting-rod, operating directly in the piston, as the particular alloy employed is found to be a satisfactory bearing metal.

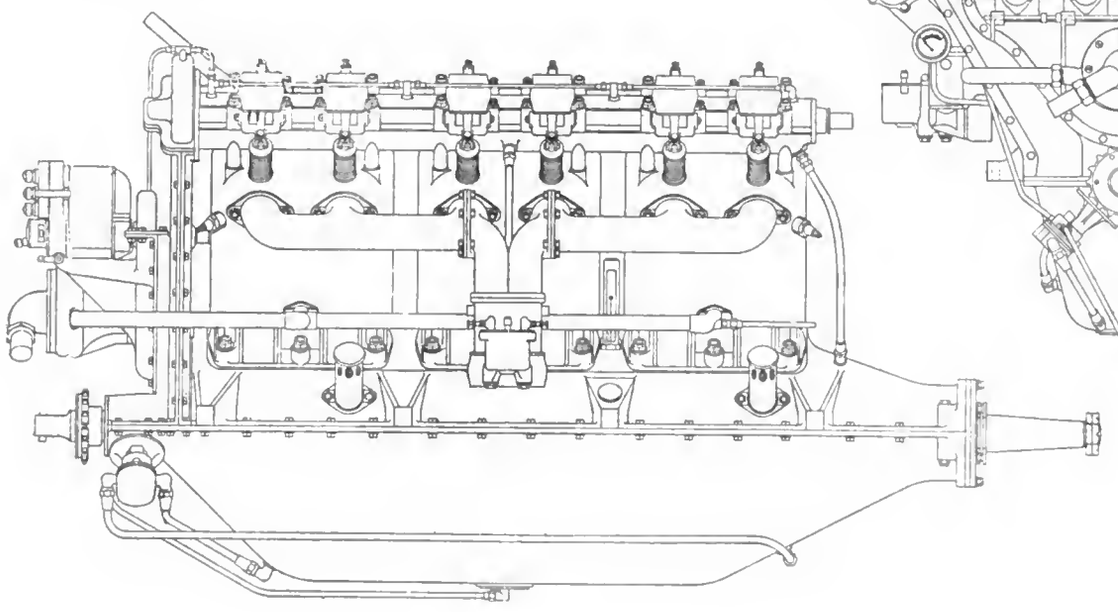
Plain Crank Bearings

A point of difference from the racing car engine is seen in the crankshaft bearing layout as ball races are not employed at this point. Instead, there are three main bearings of bronze with babbitt facing, these being fed with oil under pressure which is thence transferred to the lower connecting-rod bearings, via the crankshaft. There are no less than three oil pumps, these being arranged on the system origi-



Pistons and connecting rods of twelve-cylinder Wisconsin aviation engine. In the cross section of the pin securing the small connecting rod it can be seen that a recessed plug is used to carry oil from the crankpin to the side rod attachment. Notice the oil pipe within the main rod carrying oil to the piston pin





Wisconsin twelve-cylinder, 5-in. by 6½-in. aviation engine

nated by the Wolseley Co. of England, as two of them are used to remove oil from the crankcase, the third only being employed to force it to the bearings. Both the scavenging pumps, as they are termed by the makers of the engine, are larger than the pressure pump since their object is to keep the crankcase entirely free of oil accumulation. The purpose of this is to guard against any part being flooded should the engine be tilted to a sharp angle.

The scavenging pumps are arranged with different points of suction so that while they both exhaust the crankcase when the engine is horizontal, if it is tilted either one or the other of the pumps will still be in operation.

Oil Is Water-Cooled

It will be remembered that the oil pump and some of the pipes on the Wisconsin racing engine were placed well outside the crankcase where they were exposed to a draft of air, the cooling effect undoubtedly assisting to improve the lubrication. This idea has been elaborated in the aviation engine, since the discharge pipe on the pressure pump is taken through the interior of the lower water pipe on its way to the main standpipe from which oil is delivered to the crankshaft bearings and to the camshaft housing.

As in the racing engine, the surplus oil in the camshaft overflows down the vertical passages containing the bevel driveshaft, thus lubricating the camshaft drive gears. In addition there are also a number of oil return tubes running straight to the crankcase.

Complete Double Ignition

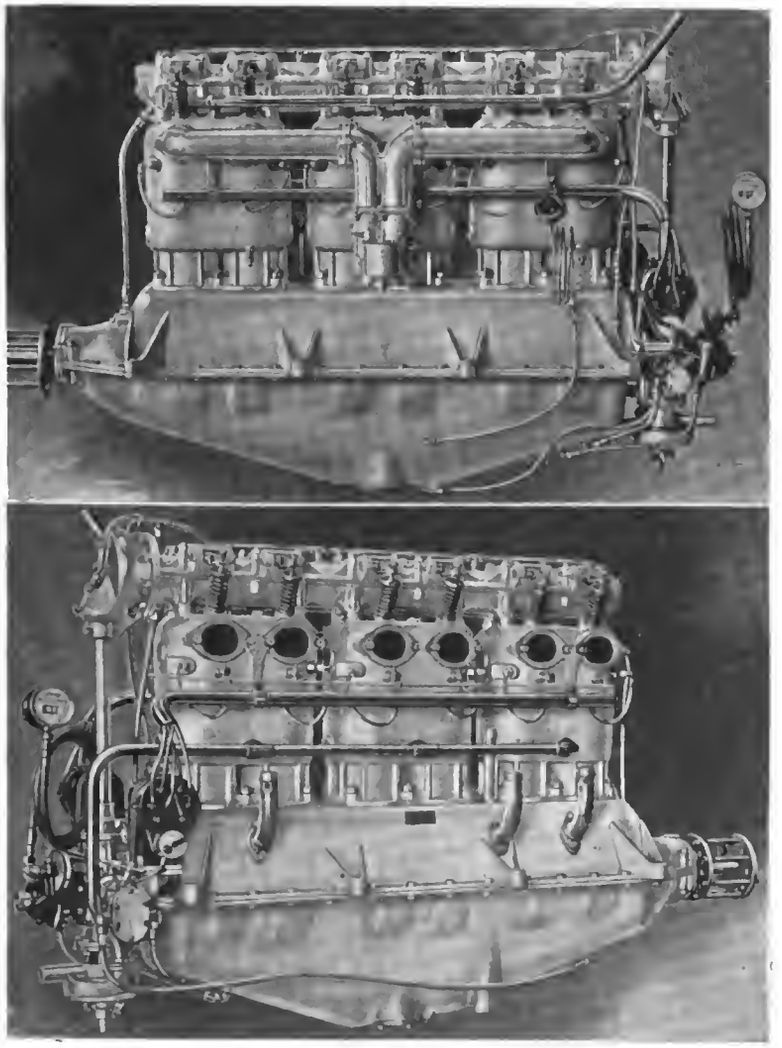
Ignition has been a constant source of trouble in aircraft and, in consequence of this, the Wisconsin engines have complete duplicate magneto systems operating simultaneously. This means that the six-cylinder has two magnetos and the twelve-cylinder four, the spark advance being interconnected. This, of course, means that in each cylinder there are normally two sparks and the Wisconsin company states that the failure of one of these sparks results in slight loss of power. There is very little difference between the six and the twelve-cylinder models, both being of the same bore and stroke and both having 3-in. valves.

In passing, it may be remarked that there are only two valves per cylinder, as against four in the racing engine, this being explained by the fact that the single large valve will operate perfectly at moderate speeds and neither of these engines is intended for very high crankshaft revolutions. One difference between the six and twelve is that the former has an I-beam connecting-rod while a tubular type is used for the twelve.

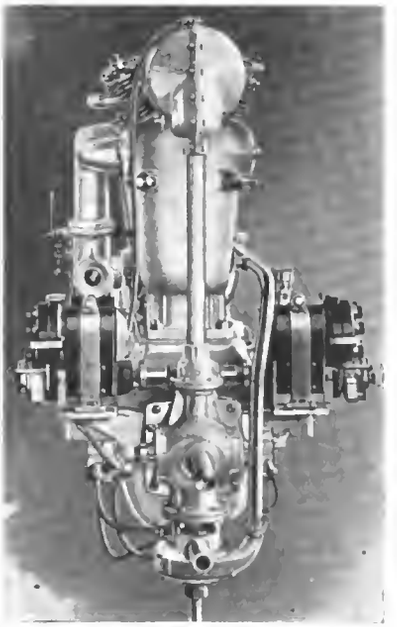
As shown in the cut, the Wisconsin company have adopted the least used type of connecting-rod for the twelve in that it is neither of the forked nor side-by-side pattern, but has a secondary rod linked to the main rod via a lug on the side of the latter.

An outstanding feature of both engines is the extremely fine workmanship employed and the use of the strongest possible kind of steel. The makers state that the six-cylinder engine weighs 600 lb. with carbureter and magnetos and develops 138 hp. at 1200 r.p.m., rising to 145 hp. at 1400 r.p.m. The fuel consumption is 0.6 pint per b.hp. hour. The twelve-cylinder is said to develop 250 hp. at 1200 r.p.m. and 280 hp. at 1400 r.p.m., while the weight of the twelve is listed at 1000 lb. with magnetos and carbureters.

These two engines, while of entirely original design, contain nothing that is abnormal. Like the other automobile engineers who have turned to the problems of flying machine power plants, the Wisconsin company has preferred to make the utmost use of its own wide experience, rather than to adopt some completely new construction. That this has been the American method is a good thing for American flying, because if there is ever a sudden demand for many engines it will not be necessary to find the weak spots in freak constructions as was the case in France in the first months of the war. American firms are tackling the job just as the European automobile manufacturers have tackled it, but America has escaped a very wasteful stage through which the European nations passed.



These views of the six-cylinder Wisconsin show the layout of all the accessories



End view of Wisconsin aviation twelve, showing the location of the two scavenging oil pumps. The layout of the two magnetos is also shown and the drive for the overhead camshaft. This illustration shows well how narrow the engine is, this being a distinct advantage for aeroplane work

Refinements in Truck Design

Abstract of a Paper Read Before the Society of Automobile Engineers at the Summer Meeting on the SS. Noronic

By H. D. Church

Chief Engineer, Truck Division, Packard Motor Car Co.

IN developing the present line of Packard worm-driven trucks, nine different experimental trucks were built and tested. The tests were run over a route in Detroit which was selected to obtain about 75 per cent of the distance over very rough, broken down block pavements. The trucks tested were overloaded continuously, were overspeeded during a portion of their testing, and were, as far as possible, kept in motion 22 hr. a day, 7 days a week.

Under these severe conditions, any faults in design were rapidly brought to light, and this paper will deal briefly with some results obtained from such test service, and also with conclusions drawn from the service result standpoint of 8 years of truck manufacture.

Front Axles

In our worm drive development work we started the use of a front axle design of I-beam section, using the inverted yoke type of steering knuckle, and it is interesting to note that the weight of the 3-ton axle of I-beam design, proved to be 17 per cent less than that of the rectangular Elliot knuckle type of axle formerly used, the stresses remaining the same in both cases. This decrease in weight was obtained in spite of the fact that the I-beam axle was of wider gage than the old type.

In the earlier experimental front axles the steering-knuckle pins were straight where they passed through the axle stock proper, and we experienced a lot of trouble due to the straight pins "belling" out the ends of the hole in the axle. This wear was, of course, in the more expensive piece of the two, and could not be corrected after it took place without re-machining the axle and putting in bushings, which in turn would do the same thing that the straight pin did.

This difficulty was entirely overcome by fitting the steering knuckle pin into the axle end on a long taper, holding it tightly in place with a nut and sleeve at the lower end, as shown in Fig. 1. This practice, in service, proved so satisfactory that it was used for the torque-arm rear end pin, where it passes through a heavy lug on the rear axle cast-steel center housing, a point where wear, due to the "belling" out of the hole, would eventually involve an expensive replacement charge.

On a heavy truck it is difficult to make a substantial connection between the steering knuckle and the steering arm, for the steering gear connecting-rod, this being the arm which carries the entire steering effort. We tried pressed hexagon fits, brazed hexagon fits, and pressed cylindrical fits, with four-key dowels, but all these constructions gave more or less trouble, and we finally forged this one lever integral with the steering knuckle, making the lever a heavy oval section.

Prior to our experimental work on worm driven trucks, we had experienced some trouble with our steering connection joints, which were of the clevis type. As originally designed, the pins were prevented from turning in the clevises by the engagement of a flatted side of the pin head with a machined lug on the steering rod clevis, and the lever eyes were bushed with bronze. The bronze bushings pounded out; so hardened steel bushings were substituted. Then we found the pins pounding out and over-sizing their holes in the clevises, and that the weight of the cross tube and connecting-rod pounded and wore the faces of the eyes and clevisee. We than commenced using hardened steel collar or "plug hat" bushings in the steering lever eyes, and in both sides of each clevis. These bushings were so arranged that the weight was carried on large diameter hardened surfaces, as shown in Fig. 2. This construction was only fairly satisfactory, as the continual pounding from solid tires, coupled with inability to retain lubricant, was the cause of too rapid wear.

We felt that we had exhausted all the possibilities of the pin and clevis type of joint, and turned to the ball-and-socket joint construction, using hardened and buffed balls and sockets, no springs being employed behind any of the sockets. This construction was an improvement over the final bushed eye and clevis design, as shown in Fig. 2, but still wore and rattled. The wear was obviously due to the slight clearance between the bearing surfaces, through which the vibration resolved itself in a succession of light hammer blows, the intensity of which increased with wear.

We next tried placing a spring behind one of the ball sockets in each joint, in order always to retain all three parts in close contact. Some experimenting was necessary to determine on a spring pressure heavy enough to allow only a slight deflection under steering effort and road shocks, in conjunction with balls of a size such that the unit pressures could be kept low enough not to cause hard steering. This construction is shown in Fig. 3.

Excellent results were finally obtained on a 3-ton truck with ball of 1⅝ in. diameter, in conjunction with a spring compressed to 300 lb. The balls and sockets are made of steel and hardened. The writer has measured balls after 30,000 miles of service, which showed less than 0.003 in. wear on the diameter, clearly indicating how the construction stands up.

Rear Axles

In 1911, when we started experimental work on worm-drive rear axles, very little information on worm gearing for truck rear axle work was available in this country, and our decision to develop an axle of this type was based largely on foreign practice. We investigated carefully the construction and service results of internal gear and worm drive axles in Europe, and were deeply impressed by the wonderful results obtained with worm gearing on the chassis of the Dennis and the London General Omnibus companies.

At that time the Hotchkiss drive looked promising, and that construction was embodied in our first worm-driven vehicle. After many months of spring breakage trouble we arrived at a design of spring with the driving eye at the rear end, which gave good satisfaction in ordinary service. On a heavy vehicle we found it impossible to make the springs as durable with the Hotchkiss drive construction as with the torque-arm and distance-rod construction, and after exhaustively testing a model with distance-rods and no torque-arm, which

resulted in an objectionable chatter when using the transmission brake, we finally decided upon the conventional type of construction, using both distance-rods and torque-arm.

Right at the start we began to have trouble with the axle driveshafts twisting off at the outer ends. European practice is to use a rigid connection at this point, between the driveshaft and the wheel hub, chiefly in connection with a floating bronze bushing for the rear wheel bearing. With the taper roller bearings, which are largely used in wheel hubs in this country, a slight amount of play is necessary in the bearings, which permits the wheel to rock slightly. This slight rocking of the wheel, in conjunction with a rigid connection between the driving shaft and the wheel hub, subjects the shaft to bending, and we found that these bending loads, in our case, were the cause of shaft failure.

For the rigid connection between the shaft and the wheel hub, we substituted a four-lug semi-universal construction, which permits a slight rocking of the rear wheel without placing any bending loads on the shaft, as shown in Fig. 4. The driving plate, which attaches to the hub, is hardened, and the driveshaft, on account of its heat treatment is also hard, so that the driving loads are taken through hardened surfaces. The pressures per square inch on these driving surfaces are as follows:

On low gear.....4230 lb. per sq. in.
On high gear.....1290 lb. per sq. in.

The wear in normal service should not exceed 0.004 in. in 30,000 miles. Since using this construction we have, so far as the writer is aware, never had a failure at the outer end of the shaft, either experimentally or on any of the thousands of trucks in service.

We also had trouble at the inner end of the axle shafts, where they engage the differential gear hubs, these failures occurring on trucks in extremely heavy service, which were fitted with high reduction worm gears. The shafts twisted off where the six splines on the inner end run out into the round of the shaft, and practically at the end of the differential gear hub. These axle shafts were made of a nickel-chromium steel, heat treated to the following physical properties:

Tensile strength.....155,000 lb. per sq. in.
Elastic limit.....120,000 lb. per sq. in.
Elongation .....16 per cent

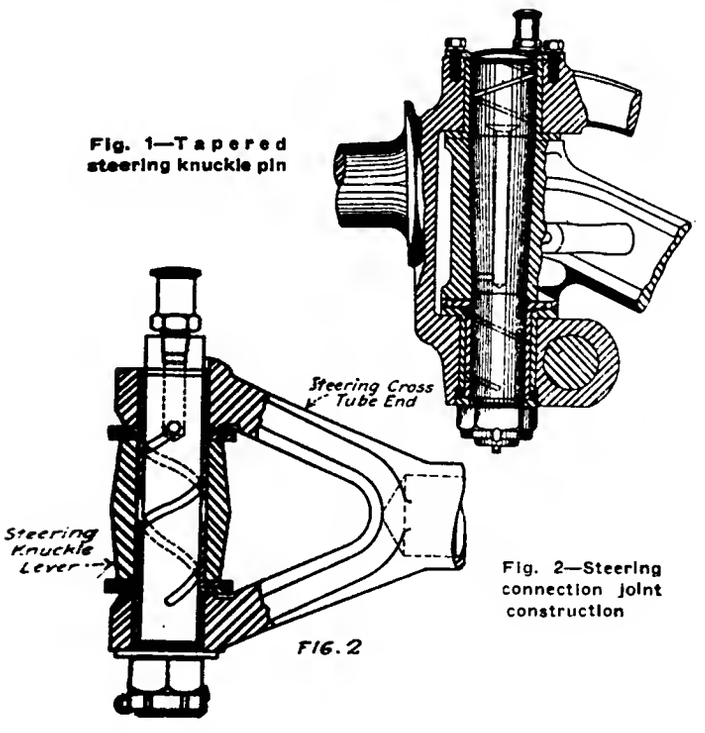


Fig. 1—Tapered steering knuckle pin

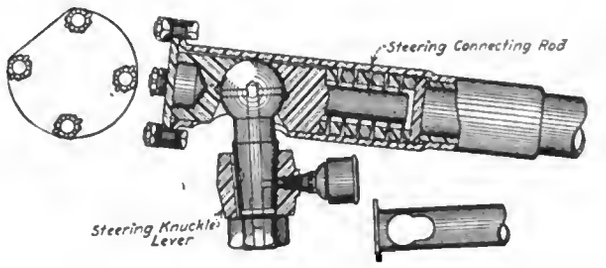
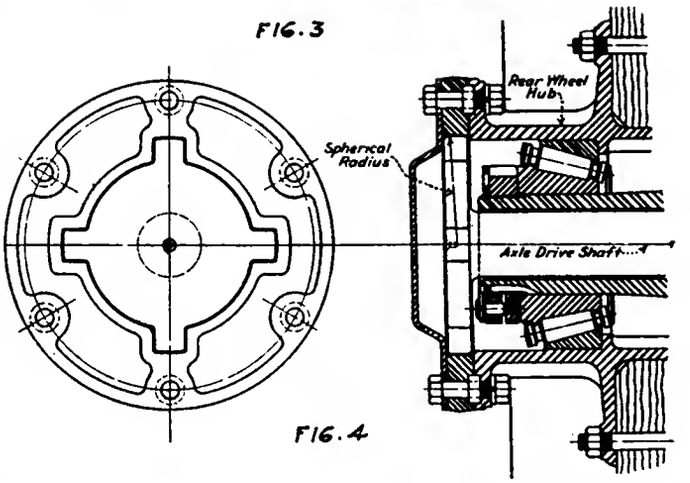
Fig. 2—Steering connection joint construction





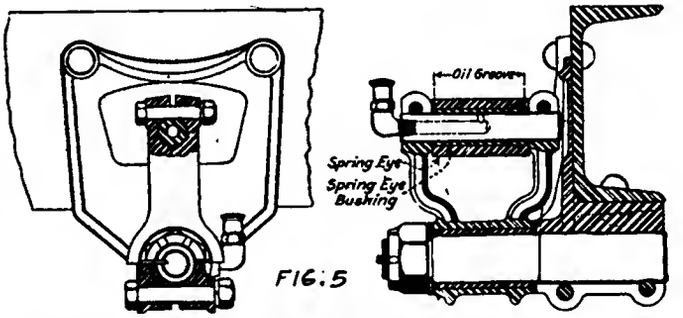


Fig. 3—Rod with ball-and-socket joint. Fig. 4—Connection between driving shaft and wheel hub. Fig. 5—Method of lubricating shackle pin

Reduction of area.....48 per cent
Hardness (Scleroscope).....50 per cent

On the 3-ton truck, with high reduction worm gears, these shafts were stressed as follows:

On low gear.....26,400 lb. per sq. in.
Due to foot brakes*.....63,400 lb. per sq. in.

And it is interesting to note that in every case of failure the shafts were twisted off from the low gear loads and not from the transmission brake loads.

In order to overcome this twisting off of shafts, we made slight changes in the chemical composition of the steel, and changed the heat treatment to obtain the following physical properties:

Tensile strength.....185,000 lb. per sq. in.
Elastic limit.....175,000 lb. per sq. in.
Elongation .....11 per cent
Reduction of area.....50 per cent
Hardness (Scleroscope).....64 per cent

To obtain these properties two heat treatments are required. The only way high stresses in the shafts can be avoided is to increase the shaft diameter materially, and such a proceeding is not desirable, as the weight of the entire axle structure builds up around the driveshaft diameter.

On our experimental worm-drive axles we experienced some trouble with overheating and subsequent failure of the double

*Stresses for foot brake determined by using coefficient of friction of 0.6 between tires and road.

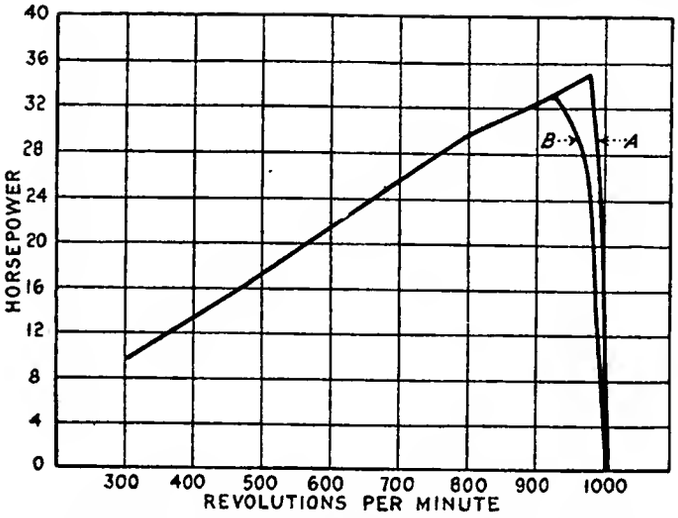

Fig. 6—Effect of governor operating and closing. Curve A, action going up. Curve B, action going down

ball thrust bearing behind the worm. By building up a dummy housing with cutout sections on top, and driving the worm by belt, we found that practically all the surplus oil carried up to the worm by the wheel impinged against the front annular ball bearing on the worm shaft, and that very little of it was forced into the thrust bearing and the annular bearing at the rear.

A cast oil trough inside the housing was provided to catch the oil thrown off the worm, and from the trough the oil was led through a cored passage into the thrust bearing housing, and allowed to find its way back into the axle case through the worm rear annular bearing. This practice provides a gravity circulatory oil feed for both rear bearings, and has been found, in service, to insure adequate lubrication.

There has been some discussion recently concerning the efficiency of worm gearing, as against that of the double side chain or the internal gear final drive. If a side chain or internal gear final drive is new, and properly lubricated, then under conditions of low rotative speed and heavy torque, the worm drive is less efficient. However, neither side chains nor internal gears can be kept lubricated, and are consequently subject to rapid wear and deterioration, while the worm drive, being completely inclosed, and running at all times in a bath of oil, is just as efficient after 30,000 miles or more of service as it is when new.

It has been the writer's experience that the truck owner is very much more interested in obtaining the minimum cost per ton mile, than in any theoretical discussion of efficiency. In considering the various forms of final drive, there are many factors which are of greater importance than the efficiency consideration. Minimum maintenance cost, durability, silence, freedom from the necessity of frequent attention, are all of more importance than efficiency, when the efficiency differences are so slight that they cannot be measured in gasoline or oil consumption.

While the manufacturing cost of a worm drive is greater than that of side chain or internal gear drives, the fundamental reason for its wide-spread use and success lies in the fact that over a given period of time and mileage, its maintenance cost is materially less than that of either of the other two forms.

Spring Shackles and Pins

These parts have been the source of a great deal of trouble in the past, because of improper lubrication and wear. The writer has never seen any grease cup having sufficient power to force grease into the loaded side of the bearing, even with no load on the truck. Grease can be forced in by using a special gun, but such a procedure, while it might be satisfactory for the owner of a fleet of trucks, is hardly feasible for the owner of one or two vehicles. When grease cups are used in conjunction with grease grooves in the pin, these grooves can be filled up with grease, but further screwing in of the grease cup only squeezes the grease out on the non-loaded side of the bearing, or by the grease cup plunger or cap. It has been our experience that grease in such grooves is never properly distributed over the loaded surfaces, as the angular motion between surfaces at this point is too slight.

This lubrication difficulty can be overcome by using oil instead of grease, feeding it into a groove along the top side of the shackle pin, whether it is the loaded side or not. The groove should be shorter than the spring bushing, and the oil-cup so arranged as to give a slight head above the groove, as shown in Fig. 5.

When the oil cup is filled, the truck is stationary and the bushing acts as a seal over the oil groove. In motion, road vibration lifts the bushing slightly away from the pin and permits the oil to flow over both sides of the groove and around the entire pin to the bottom, or in the case of a shackle pin, where the load is normally on the bottom, the oil runs over the sides of the groove and flows down around the entire pin. If desirable, felt can be used in the communicating hole between the oil cup and the oil groove, in order to cause a gradual flow of oil. This system has proved very satisfactory in service, one filling of the oil cups in the morning providing sufficient lubrication for a day's run of the truck.

The writer's experience has been that even if the shackle pin is a good fit in the shackle, and is held either by a key or a flatted lug against any rotative motion in the shackle, it cannot be prevented from wearing the holes in the shackles out of round. In time this condition also partially cuts the pin in two, and after much of this kind of wear has taken place, replacement of both the shackle and the pin is necessary; and removal of the pin for replacement is very difficult. Working on the assumption that the wear is caused by countless little hammer blows, due to inability to make the pin initially a tight enough drive fit in the shackle, the construction was changed to clamp each end of the pin in the shackle, the clamp bolt being notched into the pin and so arranged as to hold the two surfaces tightly in contact. This construction, shown in Fig. 4, has been the means of obviating entirely any trouble due to wear of the shackle or the shackle pin where they come in contact.

Radiator and Hood Mounting

The writer has experimented with several different radiator mountings, rubber cushions, coil springs, and C-shaped flat springs. The results of these experiments showed a rigid mounting to be impracticable, and that flexibility in mounting is more essential than extreme cushioning. Truck radiators are more frequently injured by the strains put upon them from chassis frame distortion than from vibration, and the most desirable mounting is one which permits frame distortion without straining the radiator assembly and which, while giving a certain amount of cushion effect, is still rigid enough to prevent excessive vibration of the entire radiator on its mounting.

It has been the writer's experience that it is impracticable to carry the front end of the hood on a ledge which is integral with the radiator casing, as if the radiator is carried on a semi-flexible mounting, it has a slight vibratory motion, relative to the chassis, which results in destroying the hood hinges and tearing out the rivets at the front end.

We are now carrying the front end of the hood on an angle-iron frame which is bolted to the chassis frame, just back of the radiator. This frame is entirely independent of the radiator and carries a water drip molding to prevent the entrance of water between it and the radiator. The construction is simple and cheap, and has quite overcome the trouble we have experienced in the past, due to the hood rubbing and

chafing its supporting ledge entirely off the radiator casing, and destroying itself and its hinges in the process.

The subject of radiators naturally brings up the fan-belt question. A fan-belt is one of the most troublesome little things with which a truck designer has to contend. Of course, in truck practice, the conditions under which the fan-belt must operate are unusually severe, as the fan speed is fairly high and the pulley center distance is short. We run our fan at approximately 1400 to 1000 r.p.m. of the engine, and have never yet found a belt which, running on 14-in. centers, has what we consider sufficient life. We have tested many different kinds of belts, both flat and V-section, but have found nothing better than the riveted segmental V-belt, and that is not entirely satisfactory. It is to be hoped that some of the belt manufacturers will develop in the near future a fan-belt which will give at least 100 per cent more life than the types at present available.

Governors

All our experimental and regular service data point to the advisability of using a governor to limit the maximum engine and truck speed. It is the writer's opinion that chassis depreciation increases almost directly as the square of the road speed, but it is manifestly illogical to try to govern all trucks of the same capacity to run at the same maximum speed, irrespective of operating conditions. For instance, a truck which is governed to the best speed for proper life and maintenance costs for operation over the rough streets of Pittsburgh, ought to be capable of running faster with no greater depreciation over level asphalt streets in Detroit.

Higher Speeds Expected

As truck engine and chassis design improves, higher engine and road speeds are going to be permissible, and the increase will probably be obtained by speeding up the engine and possibly making it smaller, using somewhat higher gear ratios in order to obtain the present activity factors on direct drive. Betterment of city road conditions will also help to make higher road speeds allowable. The writer has carried on a great deal of experimental work on centrifugal governors in order to obtain the minimum speed range for governor action without "surging" or "hunting." Assuming maximum engine governed speed is 1000 r.p.m., the governor should not cut into the horsepower curve any earlier than necessary. Our earlier governors used to start acting at 925 r.p.m., closing the throttle tight at 1000 r.p.m. After a great deal of experimental work, we have developed a governor which starts to close the throttle at 950 to 975 r.p.m., and completely closes it at 1010 r.p.m., giving a range of 6.4 to 3.4 per cent. With the engine running at 1000 r.p.m. under light loads the governor should open the throttle as quickly as possible, when the engine speed decreases from an increase in the load, but owing to the friction to be overcome in starting governor action, the governor will not open within as close a range as it closes the throttle. This difference in opening and closing action is shown on the curve in Fig. 6. The curve was made from a 4½ by 5½ in. engine, the loads being checked in speed increments of 25 r.p.m. at all speeds above 900 r.p.m. The governor, with the characteristics shown, does not hunt or surge on the road, and has a very "snappy" action, opening or closing very quickly, according to variations in the road resistance offered to the progress of the vehicle.

Unsprung Weight

There has been considerable discussion recently concerning sprung versus unsprung weights on trucks, with particular reference, of course, to the rear axle construction. While the writer has as yet no conclusive data on the subject, it is his opinion that within reasonable limits, unsprung weight on a truck is not a disadvantage. Unsprung weight on solid tires, at comparatively slow speeds, is not analogous to unsprung weight on pneumatic tires at high speeds. We once made a visual check on contact between the tires and the road, by running a worm driven and a chain driven truck at the same speed over a stretch of rough pavement, making the test with the trucks both loaded and unloaded. When loaded, both trucks carried the same weight on the rear tires, but when unloaded, the worm driven truck was slightly heavier in the rear. So far as could be judged by careful observation, the tires of the worm driven truck left the road fewer times than those of the chain driven truck, either when carrying a load or running light. This condition could indicate greater tire mileage for the worm driven vehicle, as it is obvious that when the engine is pulling, tire wear must be increased when a tire leaves the road and accelerates somewhat while in the air, due to the differential, and is suddenly brought back to its original speed by slippage against the road surface upon its return to contact.

The rear axle unsprung weights of the two vehicles tested were 2162 lb. for the worm driven, and 1612 lb. for the chain driven, both trucks being of 3-ton capacity. The side chain driven truck admittedly results in the lightest unsprung weight construction. It is interesting to note that the increase in unsprung weight of the worm drive axle over the chain drive axle is only 550 lb. or 275 lb. per wheel.

Watson Tractor for Contractors

IN designing the Watson tractor the Watson Wagon Co., Canastota, N. Y., aimed especially to meet the requirements of the contractor. The 5-ton tractor is illustrated herewith attached to the Watson 120 cu. ft. semi-trailer. This outfit can turn without backing in a 31-ft. circle. The tractor's wheelbase is 80 in. and that of the semi-trailer, 11 ft.. 3½ in. The tractor uses a four-cylinder Continental motor with 4½ by 5½-in. cylinders cast in pairs, the power plant, radiator seats and steering gear being carried on a subframe to eliminate jar. Other features are: Timken worm gear rear axle; Bosch DU4 high-tension magneto with Duplex coil for starting; Pierce governor; Brown-Lipe four-speed selective gearbox; Gemmer steering and Sheldon springs.

The Search for the Army Truck Wheel

The Composite Wheel (1) as Front and Trailer Wheel (2) as Driving Wheel—An Examination of Its Possibilities

(Continued from June 22, pages 1122-1124)

By Marius C. Krarup

AFTER dealing in the first part of this article with the characteristics in the operation of composite wheels—of the type diagrammatically shown in Figs. 1 and 2, which are repeated herewith—for use as front wheels or trailer wheels (that is, as wheels that are pushed or pulled from the axle), the more doubtful use of the type for driving wheels now comes up for consideration, and this must be less general and more searching with regard to all quantitative factors, since this type of wheel has been tried, though only in primitive forms and under primitive conditions of service, more than once in the past and yet has failed to make its way into general automobile practice or even into the heavy transportation work for which it is probably best adapted.

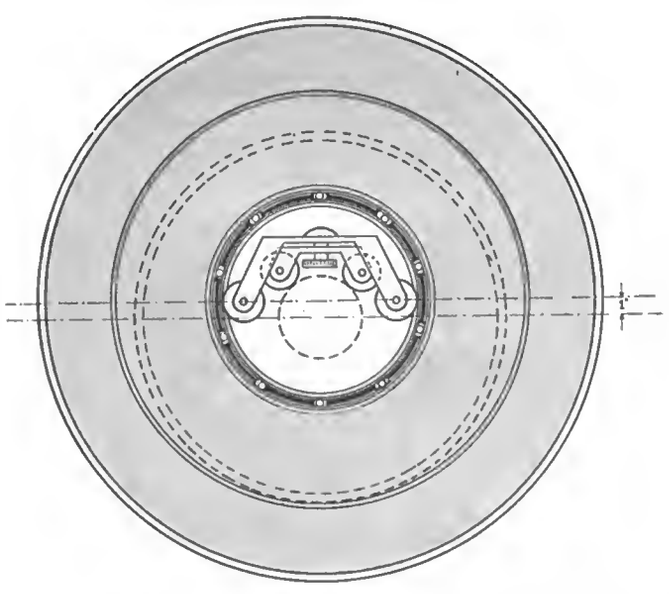
An inaccuracy in the first installment may be corrected first. Lines 16 to 11 from the bottom on page 1123 should read: The change in the location of the load pressure *in conjunction with the direct pull which may be received from the tractor additionally* must be sufficient to turn the road wheel over before the point of slippage is reached—the words here printed in italics having been omitted.

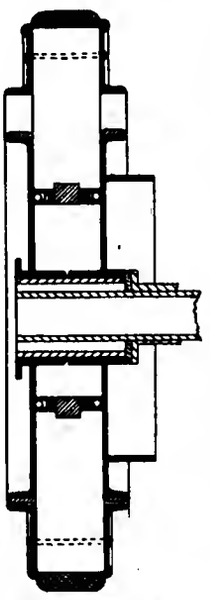
Fig. 3 illustrates diagramatically the factors and considerations which enter most prominently in the operation of the type as a driving wheel. The eccentricity of the driving wheel component in relation to the road wheel component is shown somewhat greater than in Figs. 1 and 2, partly to make the drawing plainer and partly as an indication that for heavy traction the more marked eccentricity figures out more favorably, while less desirable in the matter of making the wheel compact and attractive in appearance. The test equation presented in the following supplies a ready means for deciding the degree of eccentricity which it may be necessary to incorporate in a driving wheel of this type for any given set of service conditions, l and R being the factors affected which may be tried in the equation with different values or isolated and worked into separate formulas.

The first thing to be shown is the (1) general capacity for operating, and for this purpose the condition of a level but very heavy road is chosen. It is assumed that the friction between the driving wheel component and its track upon the road wheel component is secured by the choice of suitable materials, so that the contact point between them can rise to an angle of at least 60 degrees without chance of slippage occurring. While no greater angle than 45 degrees is employed in the example relating to steady running against heavy traction resistance, the larger angle may be desirable for starting or emergencies.

The Doubtful Points

Other conditions to be considered separately, but to which the test equation furnishes the principal clue, relate to (2) maximum speed, to (3) driving on rough roads, to (4) uphill work, to (5) downhill work and (6) braking, to (7) slippery roads and to (8) the possibility of designing this type of wheel in such proportions that the total gear ratio of a vehicle remains unchanged if the composite type is substituted for the ordinary type. Similarly the question of arranging the composite type in such manner that it may be transformed by simple adjustment into a wheel with ordinary wheel action comes up for consideration, provided it is made clear or probable that the type can be used advantageously for certain sets of conditions but not so well for other conditions which also may be encountered in the same service.





Figs. 1 and 2—Diagrams showing principal features in wheels of composite type

Fig. 1—Side view of the middle or road wheel component with tracks and thrust bearings. Device for maintaining contact of wheel sheaves with the tracks is shown in the central circular opening. Relations to axle and hub carrying the wheel sheaves are indicated in dotted lines

Fig. 2—Vertical section of assembled wheel, with omission of hub details and the central device. Brake drum is shown as integral part of the driving wheel sheave on the side of the wheel nearest the vehicle

The general capacity for operating is now to be looked into.

When power is applied and driving wheel Q is rotated forward from contact point a, there comes a moment, as when contact point b has been reached and the load L is held by the motive power at angle α, when the pressure of the load is balanced by the traction resistance. The road wheel Y still does not move, or its movement can be considered as infinitely slow. But any more advanced position of the driving wheel, such as with contact at c, causes the road wheel to turn and the vehicle to advance and to acquire momentum, the speed being determined by the angle β and a number of other factors subsequently referred to.

There is first to be determined whether the angle α is likely to be small enough to agree with practical requirements in the

starting of a vehicle, since it represents the minimum advance of Q necessary for producing vehicle movement. One has the equation

$$L \times \frac{R \sin \alpha}{p} = L f + W f \text{ or } \frac{R \sin \alpha}{p} = f\left(1 + \frac{W}{L}\right)$$

Where f is the coefficient of resistance to traction, L the load on the wheel at b, W the weight of the road wheel Y and p the distance in front of A at which traction resistance may be considered as concentrated, as depending on the hardness of the road (for given values of L and W and the wheel dimensions). $\frac{R \sin \alpha}{p}$ is then the leverage with which L is to overcome the traction resistance $f(L + W)$.

The equation, since it represents equilibrium, determines the maximum value for f.

$$f \text{ (maximum)} = \frac{R \sin \alpha}{p\left(1 + \frac{W}{L}\right)}$$

As W should be relatively small, one has approximately $R \sin \alpha = pf$ or, more accurately, $R \sin \alpha = pf\left(1 + \frac{W}{L}\right)$.

As f does not exceed 20 per cent in deep sand and p under this condition reaches perhaps a maximum of 6 inches, the system can begin to start a vehicle under these very unfavorable circumstances when $R \sin \alpha = 6'' \times 0.20$ (approximately) $= 1.20''$; and this makes α quite a small angle if the value for R—the radius of the driving-wheel track—is in the neighborhood of 15 in.

In the case of a steam vehicle or a gasoline motor truck with hydraulic transmission, these relations should be decisive to show that the composite driving wheel system will permit starting and operation at one speed or another. But for ordinary gasoline motor trucks the practical question relates to starting and running at the speed giving maximum torque for driving wheel Q, and this is the speed obtained on low gear with the motor running at normal speed. It may be 3 or 4 m.p.h. Let it be given as m m.p.h. vehicle speed. The question is then: At m m.p.h. what are the limit values for β, f and p, β being the angle, larger than α, at which a desired vehicle speed is produced)?

To avoid considering the initial acceleration of the vehicle at the start and the storing of kinetic energy, which is kept constant during running at uniform speed, the running conditions only are considered. This should be permissible, since it has been shown that a start at one speed or another is effected as soon as load L is rolled forward to contact b, even if f and p are very high.

The question of being able to apply the driving power to advantage now becomes that of deciding if the traction resistance encountered in moving the vehicle at m m.p.h. can be overcome for a given distance by the wheel action in the same length of time that the vehicle speed places at disposal. While vehicle advances the length of the arc ac at m m.p.h., can L fall the distance l which it must fall by reason of this vehicle movement and at the same time overcome the resistance to traction?

It is noted that while the power is continually keeping Y in contact with Q at c and keeping β constant (under the supposition of uniform vehicle speed here contemplated), the gravitation of L takes place independently. The rotation of Q nullifies the fall of L by exactly offsetting it, but when Q rotates as far as from a to c it offsets just the opposite movement of Q which would take place if no power were applied. The power thus raises L the height l, and the power thereby stored is the power available for overcoming the traction resistance. If this power is superior to the traction resistance, acceleration takes place, but it is here the question of examining the conditions for uniform speed. Hence we use an equation expressing the driving action taking place in the same length of time as required for the corresponding

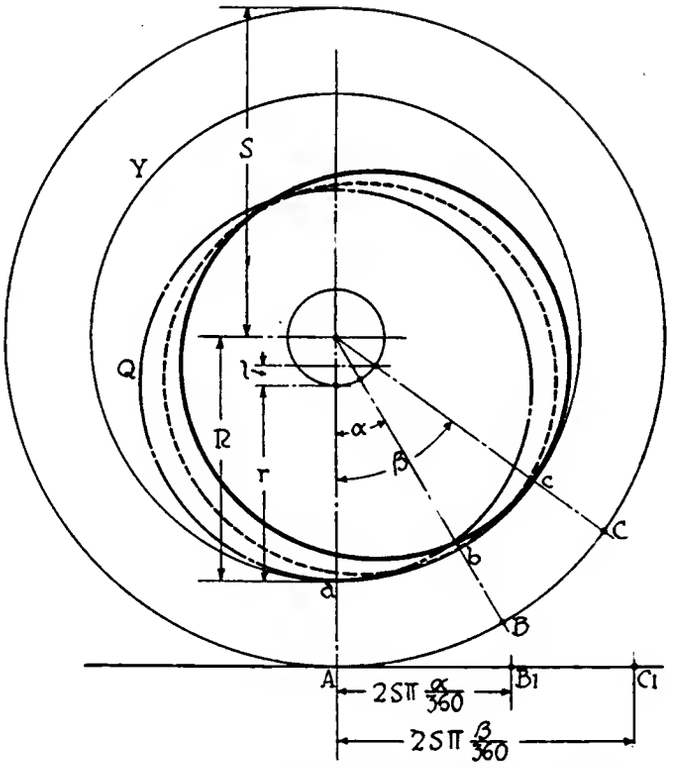


Fig. 3—Diagram illustrating factors which enter quantitatively in the operation of composite wheel type as traction wheel

vehicle movement (to make low gear torque of gasoline motor vehicle fully applicable):

L unrestricted would fall through height l in the time in seconds, $\frac{1}{4}\sqrt{l}$, (taking acceleration g as 32 ft. per second), but with resistance to overcome which equals $fp\frac{L+W}{R \sin \beta}$ if the fall of L shall be made uniform in velocity (in accordance with the foregoing), the time t for the fall is increased in the proportion which the resistance holds to L. One has therefore

$$t = \tfrac{1}{4}\sqrt{l} + \tfrac{1}{4}\sqrt{l} \times \frac{fp\frac{L+W}{R \sin \beta}}{L} = \tfrac{1}{4}\sqrt{l}\left(1 + \frac{fp}{L} \cdot \frac{L+W}{R \sin \beta}\right)$$

And as this time must equal (not exceed) the time in which vehicle advances $\frac{2S\pi\beta}{360}$ at m m.p.h., which is equivalent to $m \times 17.6''$ per second, the test equation becomes

$$\tfrac{1}{4}\sqrt{l}\left(1 + \frac{fp}{L} \cdot \frac{L+W}{R \sin \beta}\right) = \frac{2S\pi\beta}{360} \cdot \frac{1}{m \times 17.6} \text{ second}$$

in which all the linear measurements are inches and S the radius of the road wheel Y.

Example in Figures

If this equation gives a value for m (which stands for number of miles per hour) that agrees with practical values for l, f, p and β and with the vehicle speed at which a gasoline motor vehicle is best able to handle a heavy load on difficult roads, then a presumption seems to be established to the effect that the composite wheel system can be used, but it must be shown thereafter that it has special advantages and can be used on hills.

The values to be inserted in the equation may be as follows, making f and p represent high traction resistance, as in sand:

$S = 20'' =$ Road wheel radius
$R = 15'' =$ Radius of driving wheel track
$r = 12'' =$ Radius of driving wheel
$\beta = 45° =$ Angle maintained for high resistances to traction

$$l = R - r\,(1 - \cos\beta) = 3 - \frac{3}{\sqrt{2}} = 3 - 2.127 = 0.873$$

L is not important, since it is divided by itself in the equation, but its value may be taken at 1000 lb. with the value for W, the weight of Y, at 50 lb.

$f = .20$ = Coefficient of traction resistance in sand

$p = 6''$ = Distance in advance of A where f operates

These figures make the equation:

$$\tfrac{1}{4}\sqrt{0.873}\left(1 + \frac{0.20 \times 6}{1000} \times \frac{1050}{15 \sin 45}\right) = \frac{20\pi \times 45}{180} \cdot \frac{1 \text{ second}}{m \times 17.6}$$

$$0.2335\left(1 + \frac{1260}{10640}\right) = 0.2612 = \frac{15.7295}{m \times 17.6}$$

Here the left side of the equation shows that the wheel action involved, including the overcoming of the traction resistance, occupies 0.2612 sec. or about ¼ sec. Proceeding to get a value for m, one has

$$m \times 17.6 \times 0.2612 = 15.7295$$

$$m = \frac{15.7295}{4.59712} = 3.41 \text{ m.p.h.}$$

Even under the difficult traction conditions assumed vehicle can thus be operated with full benefit of the best torque and power, if the motor and gear reduction are such as to provide for normal motor speed when low gear produces a vehicle speed of 3.41 m.p.h. and the load on front wheels is not excessive. The load on the front wheels is here supposed to be taken care of in the large allowance for traction coefficient and p, in the margin left for increasing β, if necessary, up to the point where slip is likely to occur, and in the presumption of having front wheels of the same system as the traction wheels and thereby avoiding excessive resistances. But it is, of course, possible to modify the equation so as to make it include the front wheel resistances directly. The equation can, of course, be tested for high vehicle speed and smaller traction coefficients, as well as for different values of the dimensions.

[It may be doubtful, it occurs to the writer in revising these pages, if the leverage with which load L overcomes traction resistance should not be accepted as $R \sin \alpha - p$ instead of $R \sin \alpha$ divided by p. If this view is taken, however, the driving ability of the system is shown more favorably.]

(*To be continued*)

Paragraphs on Current Topics

By Marius C. Krarup

Motto: Radical Thought, Conservative Action

The real subject of this week is: Dusty or Dustless America—Which Shall it Be? For the roads make the only clouds that obscure the brightness of the belated summer. But the haunting vision of Dustless America calls for the building of one million miles of dustless roads—which would only be a road around every township six miles square, or at that rate. The cost would be that of a war, a pretty big war, but having the prosaic fault of being likely to come back with interest on the investment it seems excessive to the taxpayer who first of all wants dramatic interest. No, no more; a ten line paragraph would burst with insufficiency for holding this subject down. Dust, Roads and War, mentioning them in their order of importance, are combinedly more than a mouthful.

The Boundless Gangster Philosophy

Fewer persons know all the facts worth knowing in the management of any big thing to-day than ever before in history; mainly because there are more facts to be known. The complication of the world machinery becomes the ignorance of the individual. He is more liable to be fooled. The art of co-operation among specialists must be the cure for the resulting biological incompetence, extending alike to the leaders and the led, as in Europe's war. And here, in the art of co-operation, business men and engineers can give pointers to statesmen.

On this profound basis we begin to realize that the S. A. E., having now started on a policy of expansion of its activities and scope, should deliberately embrace statesmanship. The Automobile Club de France did so long ago. Industrial Preparedness furnishes the entering wedge. One S. A. E. foot is firmly jammed in the doorway and can hold it open for a spell, while plain members are warming up to their opportunities. Then there is the presidential campaign offering a chance for any S. A. E. orator who can learn not only to drop his pies and exes—that is easy for most of us—but also to shout fallacious platitudes with real fervor and to abandon completely that fine reserve by which engineers who respect the rules of the guild manage to convey that they would have a world of more interesting things to say if they were not restrained by grave professional considerations and responsibilities—but which is lost ignominiously on an untutored populace.

Perhaps there is not really any good reason why the S. A. E., or any other society which has gained a foothold, should not aspire to rule the world. Any society can stick to its last, like a shoemaker. Saint Simon, Auguste Comte and Nietzsche might all be quoted for expanding the activities of a bunch of men as far as they will stretch. How may the world otherwise find out who is fit to rule it?

On Advertising and Culture

As noticed last week, fastidious literary persons are finding fault with automobile advertisements. This is serious. Literature has had ample time to get used to the automobile way of doing things. Yet it does not always fall in line in the right spirit. It cajoles one minute and jeers furtively the next. Automobiles and Culture are not referred to in one breath, in the public prints affecting literary selectness, as often and spontaneously as needed for inculcating a proper and instinctive perception of their intimate association in the social structure. Being practical persons and determined to remedy this situation, we issue the following:

NOTICE.—Every now and then ex-President E. of Harvard receives press notices from other sources. No doubt, they are paid for. If he will shorten up that 5-foot shelf of books which he recommends as sure to produce a high grade of culture (if read), making it about 9 inches, and will include two or three substantial works on motors and automobile construction, we will let him have some free and high-class advertising. Until then, nothing doing.

We want a 40-hp. culture, if you please; one with a honk that scats the crowd.

Mechanical Inklings

A few months ago the number of cylinders was eagerly discussed. To-day it has been tacitly resolved that this subject is a good one to turn over to public opinion without comment. But now the slap of the piston has caught the ear of the wakeful. And what is the slap? Something like the Emperor's New Clothes in Anderson's tales, which could not be seen by anybody who was not fit for his job. It takes

special ability to hear the slap. Yet there is a murmuring about crossheads, with all they imply, to be sure of getting away from the faint sound. The exaggeration must wear itself out, but the refinement of suppressing the slap will surely be effected, wherever it may be needed, by some simple means quietly devised—perhaps only a change in dimensions of rings and grooves for aluminum pistons; perhaps a new little find in the design of steel pistons of the divided type with lengthened trunk and reduced weight.

The most dissenting opinions may be heard as to what the final type of heavy business truck will be. One of them, we venture to say, though with fear of contradiction, will have front driving with fifth wheel steering, a short wheelbase and an auxiliary small motor to drive the rear axle when needed. There will be no mechanical connection between the motors, but one will time the other through the resistance to propulsion. The rear one will have a single radical reduction gear, giving 4 m.p.h. at 800 r.p.m., with twice this speed possible and the fuel charge and composition under positive control at any speed. It will be air-cooled and easily dismountable. It will be started and stopped by clutching and unclutching it by action from the driver's seat. The fuel will not be fed through a carbureter.

If every city had X/a square miles of central area within which 4 m.p.h. was maximum vehicle speed, excepting bicycles only, a development of low-gear mechanism or low power application would follow whose effects would be incalculable. For eventually people must learn that they are not really very often in such a hurry as they now assume they always are. At the same time, belt line automobile streets would come into existence and soon would become modern Pradas, centers for light, leisurely and elegant activities along the sides and bustling with rapid vehicle traffic between the curbstones. Whether desirable or not, such an evolution comes logically hard upon the heels of the exploded contention that speed relieves congestion, which is mathematically correct but humanly impossible where little Fluffy with the saucy eyes, deep in the cushioned corner of the limousine, would rather occupy 100 sq. ft. in the street than 2 sq. ft. on the sidewalk, and insists on it.

□□□□

"Again a man having much to live with, if not for, died from skidding," is the brief obituary noticed in *Index of Contemporary Thought*—a journal often found in taxicabs and streetcar seats. But is this a mechanical, a psychological or a sociological item?

Aeroplanes for Sport and Utility

By Marius C. Krarup

WHETHER aeroplane construction is or is not to be taken up by a goodly number of automobile manufacturers, several are contemplating the possibility. Two years of hammering reports on the aeroplane feats of the war have made the expectation of a public demand for aircraft more plausible than it was previously. The impression created is one of enormous strides of progress in their construction and of huge profits in supplying the machines. In reality, though the metallic construction details are better and more easily obtained than they were, the general design shows so far no radical progress. The equipment with gyroscopic safety devices represents the most important improvement. The rest is greater size, more powerful motors; hence more speed or more carrying capacity, one or the other or a little more of both. Increased speed capacity means a quicker and therefore a safer start, but on the other hand a greater demand for skill in both starting and landing. In the air it means additional safety in some degree, but mostly when held in reserve for instantaneous application in the atmospheric emergencies known as holes or rivers in the air, which can render the steering gear and even the gyroscope ineffective for a moment that becomes fatal to the less skillful and, if the machine is near the ground, to any operator. The earth remains attractive and hard to dodge. The greater number of skillful operators and the much wider diffusion of knowledge useful for deciding on the type of aeroplane that is best for a given purpose seem to constitute the most promising factors, in addition to the gyroscope accessory, which make the situation different from what it was two years ago—so far as aeroplanes for pacific purposes are concerned.

No reports on the gyroscope are so explicit as to make it safe to infer that this balancing device is worth more in peace than in war, where it does not seem to be used extensively, interfering perhaps with the daring swoops and rapid maneuvering demanded for military efficiency. The hydro-aeroplane type is still at the mercy of rough waves and weather when it lights on the water. No small-power hydro-aeroplane has been evolved.

The automobile manufacturer in looking into the situation takes note of these things of course. Either he contemplates to manufacture for military purposes alone, in which case the cost of the machines and the danger involved in operating them are secondary, or he figures that he can also produce machines which will be in demand under peaceable conditions. As everybody understands that if peace comes tomorrow the ardor for war machines will cool the day after, or at least that such is likely to be the result here and that Europe will take time to produce her own war machines, the business viewpoint would seem to be mostly concerned with machines for peace and to rest largely on the assumption that some change has taken place which now makes the aeroplane fit for peace, although the public said unmistakably before the war that it held a different opinion.

Looks Like Doubtful Business

As heroism without due cause has no strong appeal, a good measure of safety is probably indispensable to make the aeroplane a popular civilian success, and it must be a safety that is under control by caution, not depending too much on high skill or the mere unlikelihood of encountering high-stress conditions in the elements—in the air, on water, on the ground.

Very high motor power, very great size of the machine, very great cost are all factors which would militate against popularity. The need of large storage space and sheds, large and smooth starting and landing ground would constitute another objection. Necessity for rising high in the air to be out of danger from gusts of wind would interfere with the acquirement of skill, and the civilian aeroplane must be one that invites to practice.

Taking all these things into consideration, one asks: How must then the aeroplane be constituted which shall be safe enough, good enough, cheap enough and interesting enough for the average American civilian of the class who under present conditions would consider the aeroplane at all as an instrument for sport or transportation? Does such a type exist or must it be created?

The Santos Dumont aeroplane with which Garros gained his skill at first had strong features to recommend it. It was light with a relatively large sustentation area and only a

small motor. It fluttered over the ground as a butterfly and bounced as a rubber ball, harmlessly, when it struck rough spots before rising. Its angle of incidence was naturally high until it got up and some speed was gained. But it was not much more than a learning-machine. It was less safe in the air than the machines—heavier, more powerful and with narrower and more flattened planes—which gave beginners more trouble and danger on the starting ground. It was a monoplane, which is not what war experience now recommends. On the other hand, the monoplane can readily be made with folding wings, so as to require small storage space, while no biplane has so far been made which can be taken down or set up in a few minutes by hitching the two planes separately to the body of the machine.

Perhaps easy storing is one of the requirements which must be sacrificed for the present, and in that case one turns to the demand for safe starting and safe practice without the handicap of demountable construction but short of one popular advantage. The hydro-aeroplane seems at once the most plausible type. It is practically always a biplane but with the lower plane shorter and stouter than the upper. It might be called a sesquiplane. It can be stored at the edge of a lake or river in most cases, which is usually convenient and inexpensive, but with a construction adapted for starting from water only its use would be too restricted from a business point of view. The popular type must be easy to start on either land or water, or at least easily convertible in this respect. No type of this description has made its appearance as yet. Dimensions and prices are far beyond popular limits.

In order to really invite to such frequent practice and use as alone can make a vehicle of any kind popular, the hydro-aeroplane should be sure to dump its pilot into the water gently and free of entanglements in case of a spill, or else to come down upright with the occupants on top.

The most diligent survey fails to disclose any basis for expecting a boom in private aeroplanes for either sport or utility until some radical change has been brought about in all the features relating to the convenience and safety in using them. Farmers are as a class best situated for making use of aeroplanes. People living or summering at lakes or sea shore or in the mountains come next in numbers. But one cannot imagine that many of these classes would invest in machines costing much more than one thousand dollars or machines which their children could not be trusted to use. Automobile manufacturers cannot but know that this market will not pay for the work of gradually developing an individual aeroplane from the data at present available until it may finally meet popular requirements. The transition stages in such a development are missing. But as an industrial sport for wealthy manufacturers participation in such a development should be interesting.

The aeroplane omnibus, stage or excursion craft is more nearly in line with the improvements which the aeroplane has received during these two years of war than the low-priced individual machine. It may be reserved for the public service aeroplane of large size to familiarize people with flying and constructively to bridge the gap separating the existing types of "heavier than air machines" from popularity.

Universal Has Cast Iron Bearing

Large Surface and Ready Adjustment Features of New Joint—Contains Lubricant Which Is Distributed Automatically to Working Parts

THERE seems no end to the possibilities of universal joint design as, despite the almost endless number of patterns already in use, patents for new types are granted fairly often. The latest to appear on the market is the Walker, made by the Walker Joint Co., Detroit, and this is interesting in many ways. Firstly, it has a bearing surface composed of cast iron working against steel; it has also an adjustment for taking up slack and uses the principle of the spherical joint to hold the driveshaft absolutely central, while also insuring the retention of lubricant.

The details are made amply clear by the illustrations, the sectional cut showing two right-angle views through the center of the joint and the perspective sketch the two main parts of the joint. Briefly, there is an outer casing which is bored out to a spherical form. Inside this is a ball with a shaft integral with it that is attached to the driveshaft, and an adjustable securing ring, also bored out to a segment of a sphere, holds the ball member in place and provides an adjustment for keeping the ball from developing any shake in its casing.

In the ball four slots are cut, as shown in the sketch; two of these slots are rough, being merely for the sake of saving weight, while the other two are finished accurately. Within the latter slots is placed the square-ended block, also shown in the sketch, and it is this that is the cast-iron part. There are two holes opposite each other in the outside casing, and a bolt is passed through these holes and also through the cast-iron piece. The bolt is locked in the casing so the cast-iron block turns on the bolt, giving motion in one direction, while the ball can rock to and fro within the limits of the slots, thus giving motion in the other direction.

It is easy to see that the whole joint, when assembled, can retain a considerable quantity of lubricant. In the sketch it will be noticed that there are holes drilled near the middle of the cast-iron piece, and in the sectional drawings the path of the oil within the bolt is shown by solid black. Centrifugal force takes oil or thin grease from the center and carries it out to the working surfaces at the ends. When it escapes from these it lubricates the spherical surfaces, and the rocking of the ball keeps all the lubricant churned up so that there is a continual circulation. The remaining mechanical details are made completely clear by the drawings.

The History of the Pneumatic Tire—9

Advantages of the Wired-Base Tire—Many People Did Not Believe in the Pneumatic Construction, But Favored the Solid Type—Inventions of 1892

The History of the American Automobile Industry—36

By David Beecroft

WITH the wire-edged tire the fabric could be rather long for a given rim size, and therefore loose and free to yield longitudinally. Accordingly, it could pass over an obstacle without lifting the wheel to such an extent or straining the fabric so much.

Wired-Base Tire Gains

To state the matter in another way: We may consider the constrictive tire tread as a section of a boiler shell, having the diameter of the wheel, whereas the strain on the fabric of the wired-base tire is that of a boiler shell, having the diameter of the tire itself. These diameters vary extremely, the wheel diameter being in modern automobile practice eight to ten times the tire diameter. It is not possible, however, to find in tires as actually constructed this difference, because the fabrics used are generally placed so that their threads are more or less diagonal and each tire partakes to some extent of the advantages and disadvantages characterizing the other. The wired-base tire, at first in a very small minority because the Dunlop was never properly introduced in America, has grown until it has a wide following. Its progress therefore has been more rapid than that of the clincher type.

In this struggle for a solution of the tire problem there were a very large number who did not believe in the air or pneumatic tire. It seemed incredible that the busy American public would bother with vehicles having tires that could be incapacitated by the distressingly common tack or nail in the city streets or the osage orange hedge thorn of the Middle West. Many inventors, therefore, clung to the belief that the pneumatic tire would be short-lived and some all-rubber substitute take its place, while others aimed to make such a compromise as would give them a rideable cushion tire in case the pneumatic deflated.

The Victor Arched Tire

Not only was the Victor arch tire pushed as a substitute for the pneumatic, but the Pope company held for a considerable time to the cylindrical all-rubber tire and gradually worked from this to the cylindrical inflated tire, later called hose pipe. These tires, however, would crack longitudinally above the rim where the most bending occurred and finally the top would separate from the base with results often dangerous to a bicycle rider.

To overcome this, Duryea, in 1891, brought out a cushion tire having its cushioning chambers placed radial to the wheel instead of the circumferentially placed. These holes, or air spaces, permitted the rubber around them room to compress but did not cause this rubber to bend or fold upon itself, and so it was free from the breaking so common to the other tires. Instead of the rim extending up each side of the rubber base, and inclosing a considerable weight and cost of dead rubber in the base, this Duryea cushion tire had lips at each edge of its base which extended into grooves in the rim and were cemented therein. This made a secure fastening, as it was almost impossible to pull these lips out of the grooves and the amount of dead rubber in the tire was almost nil.

Many Forms in 1892

The year of 1892 brought out a constant succession of new tire forms, some of which were radically different, and others were simply modifications of the better known types. The ideal tire of Phelps & Dingle resembled the Dunlop except that the wires were not endless, but were passed through the rim at one point and tightened by nuts. The tendency of any tire to creep around the rim rendered this form likely to tear the fabric where the wires came out of it and entered the rim, so this fastening did not find success.

Another inventor brought out a similar fastening, except the wire was endless and of double length. By putting the tire in place and drawing the wire coil tight in the tire edge, enough slack was secured in the second coil of the wire which was not in the tire edge to permit getting it over the edge of the rim. This left the tire with some slack as soon as the two coils or lengths of the wire had found their position, but with the lightly inflated bicycle tires this slight looseness did not matter much. The great danger was that the fabric would tear when the wires came through it. so this form was abandoned.

The Rostrum

Operation of an Automobile Engine

EDITOR THE AUTOMOBILE:—Please publish particulars regarding the work of an engine in an automobile. Can you explain to me the running of an automobile motor from the time it is started until it has stopped? By this, I mean, just what parts come into action, at what time and how?

Flint, Mich. M. P.

—This is a very elementary proposition as there is nothing very complicated to the automobile engine. From the time it is started until it is switched off at the end of the run the following operations take place:

The engine is first cranked. In the older cars this is done manually by turning a hand crank on the end of the crankshaft. In the modern engine the cranking is done mechanically by an electric motor. The starting switch is closed, allowing current to flow from the storage battery to the starting motor. This motor is in engagement with the crankshaft of the engine and as it turns over due to the electric current from the storage battery it cranks the engine. During the cranking of the engine the downward motion of the pistons on the suction stroke draws in air into the carbureter and gasoline from the carbureter jet. These mix in the mixing chamber of the carbureter and pass into the engine through the intake valve. The next stroke compresses the charge in the cylinder and when the piston reaches the top of the stroke a spark occurs, due to the electric ignition apparatus operated in connection with the engine.

This spark explodes the gas compressed in the cylinder which causes it to exert a pressure due to its quick expansion upon the head of the piston, pushing the piston down which in turn carries with it the connecting-rod that rotates the crankshaft. The crankshaft is connected with the clutch and then the drive passes back through the gearbox, driveshaft and axles to the wheels. Once the first explosion has occurred the action of the engine after that becomes automatic and necessity for the cranking medium ceases to exist. While one cylinder is exploding another is taking in a fresh charge, in the multi-cylinder engine. The action of the four-cycle engine as used in automobiles is to draw in the gas on one stroke, compress it on the succeeding, explode it on the next and exhaust it on the last. The drive is from the piston to the connecting-rod and then to the crankshaft. Geared to the crankshaft is the cam action for the valve and the auxiliaries such as the generator, ignition distributer unit, etc. All motion is stopped as soon as the ignition is switched off, stopping the gases when exploded.

Order of Magneto Spark Delivery

Editor THE AUTOMOBILE:—A six-cylinder engine fires 1, 4, 2, 6, 3 and 5; the magneto is geared 1½ to 1. Are cylinders 1, 2, 3 sparked by one cam of the magneto and cylinders 4, 5, 6 sparked by the other cam?

Nashua, N. H. W. H. C.

—A magneto generally gives two sparks to the revolution, therefore, when geared 1½ to 1 the magneto furnishes six sparks for every two revolutions of the crankshaft or three sparks per revolution. Since the engine will fire 1, 4, 2 on the first revolution, cylinder No. 1 will have the top break, cylinder No. 4 the lower break, and cylinder No. 2 the top break. On the next revolution cylinders 6, 3 and 5 will fire allowing No. 6 to have the lower break, 3 the top and 5 the lower. Thus, the same cam breaks fire cylinders 4, 6 and 5 and 1, 2 and 3 as you state in your letter.

Adjusting Differential on 1915 Reo

Editor THE AUTOMOBILE:—Kindly publish diagram of differential of 1915 Reo and give manner of adjustment. This car has too much slack in driving shaft, which I believe to be from transmission back. Advise how to adjust this.

I have a friend who drives a Hupmobile and to every tank of gasoline he adds a quart of cylinder oil. He insists that it is a benefit and that it would likewise prove beneficial to the Reo. Both motors are in perfect condition. Kindly advise me whether or not this adding of oil would improve running of Reo motor and if so, please explain why.

Coushatta, La. S. M. C.

—The lost motion you speak of as existing in the driveshaft is something that cannot be adjusted without securing new universal blocks. This probably will remove the condition which now exists. The diagram you request is not necessary in making the matter clear.

The practice of adding oil to the gasoline is quite a common one and will do no harm. However, if the cylinders are securing sufficient lubrication from the regular oiling system there is no necessity of increasing the amount of oil feed by adding it to the gasoline. This method of oiling a motor was used to a large extent when two-cycle engines were employed in automobiles. It is quite common to use cylinder oil in the gasoline in two-cycle marine practice even to-day.

Information on the Diesel Engine

Editor THE AUTOMOBILE:—Kindly publish information as to how the fuel oil is forced into the cylinder of the Diesel motor.

2—Is the fuel mixed with air, or oil alone forced in?

3—Is the fuel injecting mechanism of necessity slow speed?

4—What is the lowest compression that could be successfully used in the Diesel type with kerosene fuel?

5—What are the faults of the fuel-injecting mechanism as used on Diesel types of motors?

Tampa, Fla. L. C. H.

—The principle of the Diesel engine is as follows: It operates on the four-stroke cycle and has exhaust and inlet valves just like a conventional engine. The inlet valve admits pure air only and the compression space is very small, so that the air charged is brought to a high pressure. In the cylinder head there is a small valve through which fuel is forced by air raised to a very high pressure indeed in a separate three-stage pump. The degree of compression in the main cylinder has to be such that the charge of pure air will be heated to a temperature sufficient to ignite the fuel. Thus a Diesel gasoline engine would require moderately low compression while a Diesel engine for burning the heaviest

kind of crude requires a much higher compression. The reason that the Diesel engine has not been developed in small sizes is mainly the difficulty in handling extremely small quantities of fuel. In the Diesel system the high pressure air is admitted to the fuel valve at the top of the compression stroke and fuel is thrown in during nearly the whole of the working stroke, burning in the compressed air as it enters the cylinder. When a cylinder is so large that it will consume a wineglass full of fuel each stroke, it is easy to measure and control the fuel, but where it would need only a few drops the measurement becomes far more delicate.

Use Standard Bulbs on Dodge

EDITOR THE AUTOMOBILE:—Can 40 candlepower nitrogen headlight bulbs be used on a 1916 Dodge car without battery damage?

2—Approximately how much daylight driving would be necessary to keep the battery up?

3—When driving at night and indicator shows charge with all lights on, is the generator not supplying enough current to take care of lights and charge battery?

Canton, Ohio. T. L.

—We do not recommend the use of any other headlight bulbs than the standard 12 volt., 15 candlepower.

2—It is impossible for us to make any statement as to how much daylight driving would be necessary to keep the battery up. It depends entirely on how much night driving is being done, and how many times the car is started during the day. The starter-generator under the usual running conditions will keep the battery properly charged. If for any reason the car is subject to a lot of abnormal driving such as driving most of the time at night at low speeds and doing a great deal of starting during the day, the battery should be checked up by means of a hydrometer about once every two weeks. This will show whether the car is being driven enough at charging speeds, to keep the battery in good condition.

3—It does not necessarily mean when driving with the lights turned on and the battery indicator shows charge, that the battery is being charged, as only enough current may be generated to light the lights, as the indicator simply shows whether the starter-generator is charging or discharging. However, when traveling at 18 miles or more, the starter-generator will be charging the battery whether the lights are turned on or not.

Graphite as Lubrication Aid

Editor THE AUTOMOBILE:—I do quite a little car driving but do not have time to take care of my car. I would like to know whether flake graphite in the oil would be of any help, and how much? An oil man told me that it would keep an engine in perfect order as it reduced friction.

Chester, N. Y. C. F. J.

—If the proper grade of graphite is used it will be an aid to lubrication. It is very important, however, that you secure the correct graphite as all graphites are not lubricants, strictly speaking. The manufacturers of graphites can furnish you with the proper grade for various purposes.

Timken 5-Ton Worm-Driven Truck Axle

UP to this time the popular sizes of worm-driven truck axles have been within the range from ¾-ton to 3-ton, there has been a growing demand for this type of drive in larger truck units, and to meet such, the Timken-Detroit Axle Co., Detroit, Mich., has come out with a 5-ton unit that has long been in the process of development. This new Timken product is doubtless one of the largest axle types of the worm-drive form yet produced, and it speaks eloquently of the ability of the engineers who are responsible for its design.

This new axle has a pressed-steel housing of great strength, and is equipped with the Timken-David Brown worm gearing with Timken roller bearings. The worm is mounted over the wheel, and throughout the construction is typically Timken. That a large factor of safety has been used is evidenced from the fact that the axle is capable of carrying on the rear tires a weight of 15,000 lb.

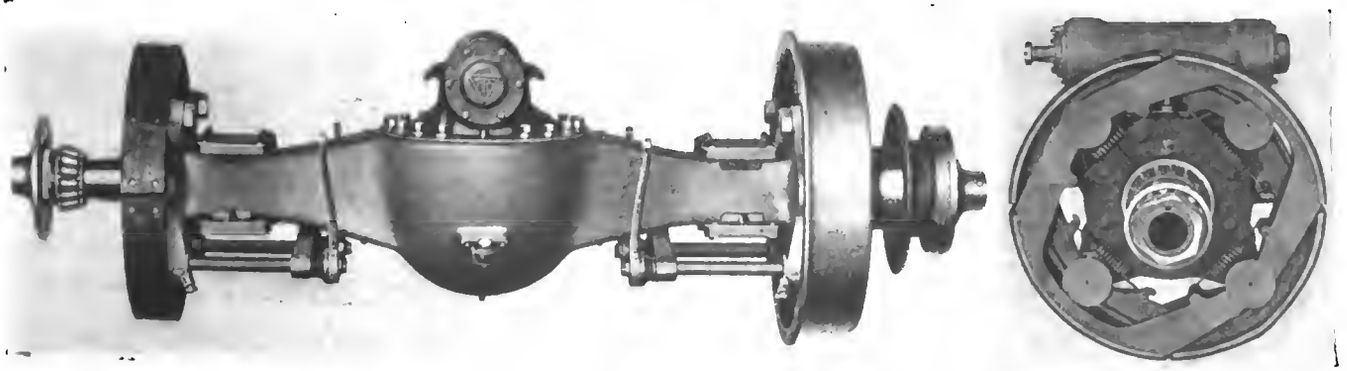
The load-sustaining portion is continuous from spring seat to spring seat, and is a pressing 6 in. square at either end under the spring seats, and enlarges to a spherical shape in the center to provide clearance for worm gear and differential. The square section at the ends has been used in order to give a firm seat for the spring saddles and added strength where it is needed. The center is open at the top for the attachment of the carrier flange which holds the worm shaft and its bearings, the worm gear, differential and bearings being in one complete unit. The ends of the housing are flanged to a large diameter and the brake spider is riveted to this flange substantially.

The axle is designed as a floating unit, and the wheel bearings are mounted on chrome-nickel steel tubes which extend inwardly toward the worm almost to the differential bearings, thus making a sturdy mounting for the shafts, the bearing supports being filler pieces welded and riveted to the housing, and the tubes forced into these filler pieces under great pressure. Thus the axle has a truss or bridge construction, which is the strongest type.

Brakes are 24 in. in diameter and 4 in. wide and are of the internal duplex form. Substantial flanges on the drums provide against distortion.

Some of the dimensions are:

Overall length—89⅞ in.
Centerline to bottom of housing—9 11-16 in.
Centerline to top of carrier—13⅛ in.
Centerline to forward end of worm shaft—13¼ in.
Centerline to centerline of spoke—69½ in.
Diameter of axle shafts—2¼ in.



Left—New 5-ton Timken floating worm-drive axle for trucks. Right—Brake construction and worm mounting

ACCESSORIES

Ryerson Connecting-Rod

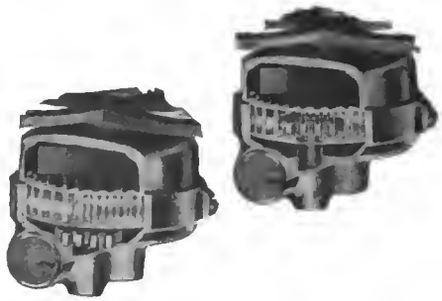
THIS new connecting-rod and bearing enables the owner or repair man to install in a Ford engine a bearing of the same type used in practically all the high-priced cars. The outstanding feature of this product is the fact that it does not require a complete overhauling of the engine but may be installed in a few minutes. When a car has been equipped with these Quick Change rods and bearings, new bearings may be slipped in when necessary without tearing down the entire engine. The bearing is the Glyco patented skeleton construction of reinforced babbitt, consisting of a strong skeleton introduced into a high-grade babbitt and finished with great accuracy. Special laminated shims come with each set of bearings which are inserted one on either side where the halves meet. These are composed of metal leaves 0.002 in. thick and are peeled off at intervals as the bearings gradually wear so that the fit will be as nearly perfect as possible at all times. Individual boxes each contain one complete connecting-rod and bearing.—Joseph T. Ryerson & Son, Sixteenth and Rockwell Streets, Chicago, Ill.

Muller Wash Lamp Stand

A large reflector with four lights is horizontally mounted on a vertical standard with a cast-iron base supported on three casters. The position of the reflector is adjustable. Fifteen ft. of cord are supplied. The device is guaranteed to be waterproof. Price, $10 and up.—Edward Muller, West New York, N. J.

Rex Lock for Fords

The Rex lock replaces the regular Ford steering gear cover, and is attached to the internal gear case just below the steering wheel. The case contains an internal gear and pinions. When the key of the lock is turned, a geared sector is moved down between two of the gears, locking the steering gear so that it cannot be moved. Thus when the lock is set the car can move only as the front wheels are set, which may be straight ahead or at any angle. The maker states that the lock cannot be picked, and that if it were smashed the steering gear would be disabled. No drilling is required to install the device and only ordinary tools are needed. It sells for $4.—De Tamble Mfg. Co., Chicago, Ill.



Rex lock for Ford steering gear

Storm & O'Hair Reboring Tool

Cylinders used on any make of engine and from 2¾ to 5 1/16 in. diameter may be rebored by this adjustable machine which has two thread bars, one left and one right, the former being for Ford engines and the latter for all other makes. The regular machine is furnished with seven lead rings as follows: 3⅝, 3⅞, 4, 4⅛, 4⅜, 4¼ and 4½ in. Price, $60. Small head and attachments for boring cylinders from 2¾ to 3¾ in., four lead rings. Price, $20. Large attachment, working in connection with regular machine, two lead rings, $15.—Storm & O'Hair, Thompson, Iowa.

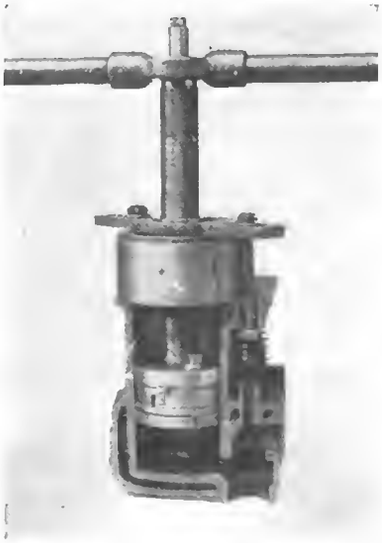
Hand-I-Wash

This is a combination of water, soap and towel put up in a can about 3 in. in diameter and 1 ft. high. By turning the outlet on the top of the can the liquid may be sprinkled on the hands and is just like soap and water. The hands are then dried by tearing off a section of the paper towel which is on a roller in the body of the can. Both liquid and towel may be purchased separately so that when the can is empty, it may be refilled. The liquid will remove all kinds of dirt, grease and oil, is antiseptic and neutral, containing neither acid nor alkali. Price $1; refiller, consisting of towel roll and tube of liquid 50 cents.—Tay-Miller Mfg. Co., 1714 Cherry Street, Philadelphia, Pa.

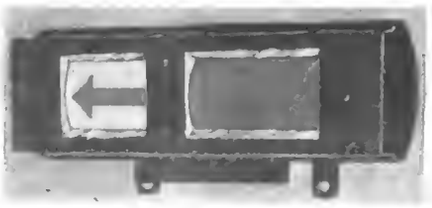
Water, soap and towel in one can

Automatic Signalite

A rear safety signal which operates by day or by night and indicates when a

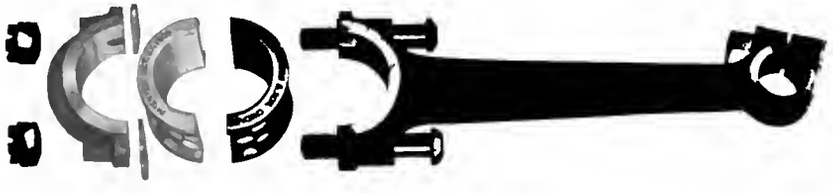


Storm & O'Hair reboring tool outfit

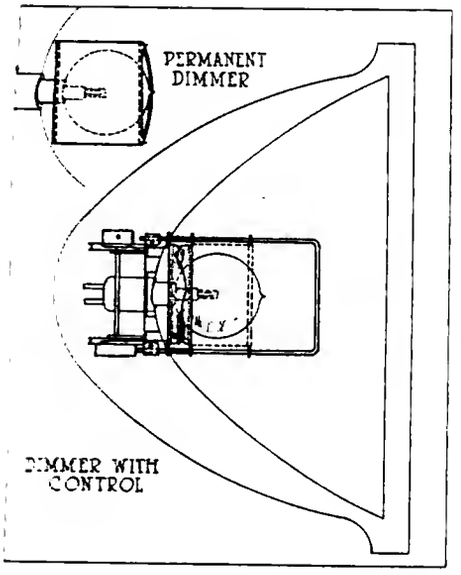


Automatic Signalite

Storm & O'Hair reboring tool outfit



Ryerson Quick Change connecting-rod and bearing assembly for use on Ford cars



O-U-Lite dimmer in which a cylindrical silk sleeve is used to remove the glare

turn to the right or the left is to be made, slowing down, stopping and backing to the right or left. These various functions are performed by the turning the steering wheel, depressing the brake, engage and reverse, etc. A hand lever attachment for indicating turns to the right or left will also be supplied, if desired. It is illuminated with a standard tail light bulb and carries the license plate. It may be attached to any car in 30 min., it is said.—Signalite Mfg. Co., Kansas City, Mo.

O-U-Lite Dimmer

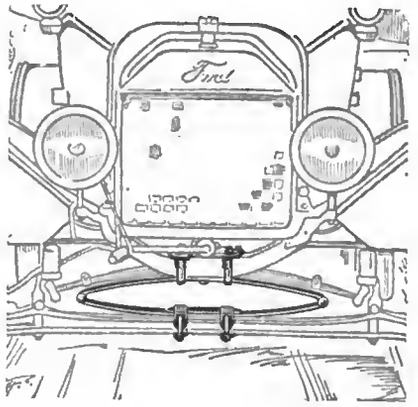
This is a small silk shade and in the permanent type is held by a metal frame and completely incloses the lamp bulb. In the control type the silk shade may be telescoped against the back of the reflector to give full power from the lamps. Price for electric lamps, $1, with control on lamps, $3.50, with control on steering post, $5.—O-U-Lite Co., Racine, Wis.

Twin Safety Spring Check

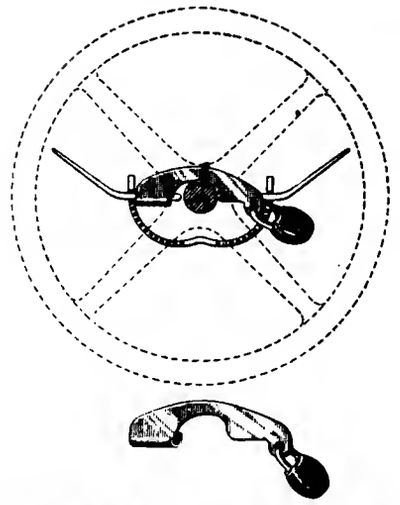
This is a device which is particularly for Ford cars and is designed to prevent side sway and lurching when driving at high speed or over rough roads, consists of a full elliptic single leaf spring which is clamped between the cross frame member and the front axle. Price, $3.—Twin-Rim Co., 103 Massachusetts Avenue, Boston.

National Mix-O-Lock

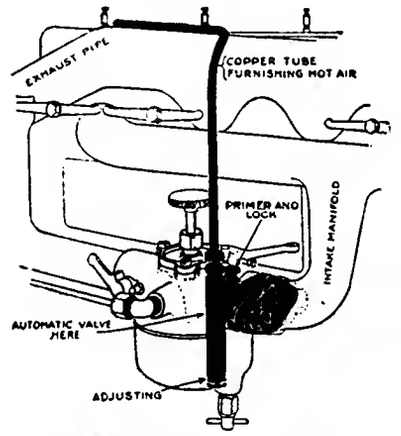
This device combines a gasoline saver, primer, carbon remover and lock for Ford cars, consisting of a flange which bolts between the carbureter and the intake. There are no holes to be drilled or capped; all that is required is a wrench. It contains an automatic valve which admits more air when required and has a plug which may be removed, thus preventing the starting of the motor, as



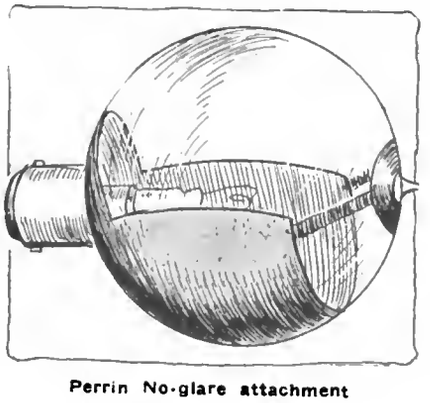
Twin safety check for Fords



Adams spark and throttle lock for use on Ford cars



National Mix-O-Lock for Fords



Perrin No-glare attachment

the absence of the plug renders it impossible for gasoline to be sucked from the spray nozzle. Price, $2.—National Motor Supply Co., 5606 Euclid Avenue, Cleveland, Ohio.

Perrin No-Glare

This device is not a dimmer but an intensifier of the light on the road. The No-Glare is a deflector made of special aluminum which fits snugly around the lower half of the light bulb, without any vibration or danger of breaking the bulb.

The Perrin device complies with the recommendations of the Society of Automobile Engineers, as none of the light rays are over 42 in. above the road at 75 ft. from the car. It gives 10 ft. of side light 10 ft. in front, and objects are clearly lighted 150 ft. in advance of the car.—Perrin Mfg. Co., Detroit, Mich.

Adams Spark and Throttle Lock

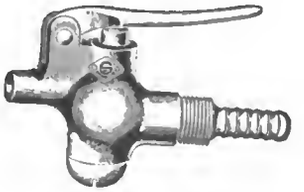
This lock is designed to control both the spark and throttle levers on Ford cars, hooking over one lever and being held to the other by a padlock. The devices are made of sheet steel and nickeled, the lock being a four-tumbler type and furnished with two keys. Price 50 cents.—A. L. Adams, 18 Normond Street, Springfield, Mass.

Stevens Air Cleaner

This device, called the Stevens automatic blow cock and cleaner, is designed for dusting the cars, cleaning motors, removing chips from bench and machine tools, etc., wherever compressed air is available. It is provided with a convenient operating handle and the valve has a tapered metal seat. Price, 75 cents.—Stevens & Co., 375 Broadway, New York City.

Wall Handle for Soldering

This steel handle for soldering coppers is designed to stay in its place indefinitely without breaking, splitting or burning, which wood handles will not do. The handle is of pressed steel, of heavy gage, and a grooved projecting member provides a seat for the iron tang of the soldering copper. Once the handle and tool are put together they are practically permanently attached. The makers state that the handle will not grow too hot for comfort, no matter how hot the copper may be. Made in three sizes: No. 1, for 1 and 1½-lb. coppers; No. 2, for 2 and 3-lb. coppers, and No. 3, for coppers up to 6 lb.—Stewart & Co., New York City.



Stevens air cleaner

Automobile Nomenclature

Complete Report of the Nomenclature Committee of the S. A. E. as Accepted by the Society at Its Summer Meeting—Correct Names for All Car Parts

AFTER a number of meetings held during the past year in conference with engineers and representatives of service departments responsible for the naming of car parts in their own organizations, the following list of names has been prepared and is offered for acceptance by the Society.

An attempt has been made to include in the list the more important parts throughout the whole car, bolts, studs and the like being indicated in general terms. Body parts have not been included generally nor parts of some units such as carbureters, which vary so much in construction as to make anything like uniform nomenclature very difficult.

Definitions of different types of construction have been included for several units in order to encourage uniform terminology in descriptions appearing in the trade press and in catalogs, as well as in the technical discussions of the Society. Definitions of different types of bodies are also included, because it is thought that some authority should take action to make possible the use of names which will be understood generally, rather than those which are meaningless except to persons conversant with the terminology peculiar to individual manufacturers. It is surprising how many distinctly different types of body are being sold under the name "brougham," for instance.

A scheme of classification based entirely on assemblies is impracticable for general use, on account of diverse arrangement of elements of so-called conventional cars. The classification proposed is therefore based largely on function.

In its present form the report can be used as a guide in making up lists of parts, or for any purpose by those familiar with automobile construction. It is probable that at some time in the near future sketches illustrating various of the parts listed in the report will be supplied.

DIVISION I—CYLINDERS

Group
- 1—Cylinders.
- 2—Crankcase.
- 3—Crankshaft.
- 4—Starting-crank.
- 5—Connecting-rods.
- 6—Pistons.

DIVISION II—VALVES

- 1—Camshaft.
- 2—Valves.

DIVISION III—COOLING SYSTEM

- 1—Fan
- 2—Radiator.
- 3—Pump.
- 4—Pipes and Hose.

DIVISION IV—FUEL SYSTEM

- 1—Carbureter and Inlet Pipe.
- 2—Carbureter Control.
- 3—Carbureter Air Heater.
- 4—Fuel Tank.
- 5—Fuel Pipes and Feed System.

DIVISION V—EXHAUST SYSTEM

- 1—Exhaust Manifold.
- 2—Exhaust Pipe and Muffler.

DIVISION VI—LUBRICATION SYSTEM

- 1—Oil Pan or Reservoir.
- 2—Oil Pump.
- 3—Oil Pipes, Strainers, Gages.

DIVISION VII—IGNITION

- 1—Spark-plugs, Cables and Switches.
- 2—Ignition Distributor.
- 3—Magneto.
- 4—Ignition Control.

DIVSION VIII—STARTING AND LIGHTING EQUIPMENT

- 1—Generator.
- 2—Starting Motor.
- 3—Wiring.
- 4—Battery.

DIVISION IX—MISCELLANEOUS ELECTRICAL EQUIPMENT

- 1—Lamps and Wiring.
- 2—Switches and Instruments.
- 3—Horn.
- 4—Miscellaneous.

DIVISION X—CLUTCH

- 1—Clutching Parts:
  - Cone Clutch.
  - Disk Clutch.
  - Plate Clutch.
- 2—Releasing Parts.

DIVISION XI—TRANSMISSION

- 1—Transmission.
- 2—Shifting Mechanism.
- 3—Control.
- 4—Propeller-shaft.

DIVISION XII—REAR AXLE

- 1—Housing.
- 2—Torque Arm and Radius-rod.
- 3—Drive Pinion.
- 4—Differential.
- 5—Axle Shafts.

DIVISION XIII—BRAKES

- 1—Outer Brake.
- 2—Inner Brake.
- 3—Pedal (or outer) Brake Control.
- 4—Hand (or inner) Brake Control.

DIVISION XIV—FRONT AXLE AND STEERING

- 1—Axle Center.
- 2—Steering-knuckles.
- 3—Steering-rods.
- 4—Steering-gear.

DIVISION XV—WHEELS

- 1—Front Wheels.
- 2—Rear Wheels.

DIVISION XVI—FRAME AND SPRINGS

- 1—Frame.
- 2—Frame Brackets and Sockets.
- 3—Front Springs.
- 4—Rear Springs.

DIVISION XVII—HOOD, FENDERS AND SHIELDS

- 1—Hood.
- 2—Engine Shield.
- 3—Fenders and Running-boards.
- 4—Windshield.

DIVISION XVIII—BODY

- 1—Floor-boards and Dash.
- 2—Body
- 3—Upholstering.
- 4—Top.

DIVISION XIX—ACCESSORIES

- 1—Speedometer.
- 2—Tire-pump.

General

Where terms "front" and "rear" are used, "front" should always be toward the front end of the car. These terms are sometimes confused in regard to parts that are mounted on the dash. The front side of the dash is always that next the engine.

Where parts are numbered, No. 1 should be toward the front of the car. For instance, No. 1 cylinder is the one nearest the radiator (in conventional construction).

"Right" and "left" are to the right- and left-hands when sitting in one of the seats of the car.

Studs, screws and bolts shall take names from parts they serve to hold in place, although they are assembled with other parts. For example, the cylinder stud is permanently screwed into the crankcase but holds the cylinder in place.

The name "engine" should be used rather than "motor" to avoid confusion with electric motors and to secure a lower freight rate.

DIVISION I—CYLINDERS

Group 1—Cylinders.
- Cylinder:
  - L-head cylinder (valves on one side of cylinder).
  - T-head cylinder (valves on opposite sides of cylinder).
  - I-head cylinder (valves in cylinder head).
  - F-head cylinder (one valve in head, other on side directly operated).
- (Cast in block, not cast en bloc.)
- (Cylinders of V-type engines should be numbered 1R, 1L, 2R, etc.)
- Inlet-valve cap.
- Exhaust-valve cap.
- Valve-cap gasket.
- Cylinder-head.
- Cylinder-head gasket.
- Cylinder-head plug.
- Water-jacket top cover.
- Water-jacket top cover gasket.
- Water-jacket side (or front or rear) cover.
- Valve-spring cover.
- Valve-spring-cover gasket.
- Valve-spring-cover stud.
- Valve-stem guide.
- Priming-cup.

Group 2—Crankcase:
- Crankcase.
- Barrel-type crankcase.
- Split-type crankcase (split horizontally, at or near center line of crankshaft).
- Crankcase upper half.
- Crankcase lower half (used only when the lower half contains bearings. A crankcase of either barrel or split type, in which all the bearings are mounted directly on the part to which the cylinders are attached, is called a "crankcase," the terms "upper half" and "lower half" not being used).
- Oil pan (used for lower part of split-type or barrel-type crankcase, whether this serves as an oil reservoir or not).
- Oil-pan drain-cock (or -plug).
- Breather.
- Oil-pan gasket.
- "Bushing" instead of "bearing" for removable and renewable lining used in a plain bearing.
- Crankshaft front bearing bushing (upper half and lower half).

Crankshaft front bearing cap.
Crankshaft front bushing support (sometimes used in barrel-type crankcase).
Crankshaft rear bearing bushing.
Crankshaft rear bearing shims (other shims accordingly).
Crankshaft center bearing bushing (if only three bearings or if all except end bearings are alike).
Crankshaft second bearing bushing, etc. (if more than three bearings, for example, front bearing, second bearing, third bearing, fourth bearing, rear bearing).
Hand-hole cover.
Hand-hole-cover gasket.
Timing-gear cover.
Timing-gear-cover gasket.
Flywheel housing.
Generator bracket (other brackets take name of part supported).

Group 3—Crankshaft:
Crankshaft.
Flywheel.
Crankshaft timing-gear (or sprocket).
Crankshaft timing-gear key.
Flywheel starter gear.
Crankshaft starter sprocket.
Flywheel studs.
Clutch-spring stud.
Crankshaft starting jaw (or pin).

Group 4—Starting-crank:
Starting-crank.
Starting-crank jaw.
Starting-crank shaft.
Starting-crank handle.
Starting-crank-handle pin.

Group 5—Connecting-rods:
Connecting-rod.
Straight connecting-rod } V-type engine.
Forked connecting-rod }
Connecting-rod cap.
Connecting-rod bushing (upper half and lower half).
Connecting-rod cap stud (or bolt).
Connecting-rod cap nut.
Connecting-rod bearing shims.
Connecting-rod dipper.
Piston-pin bushing.

Group 6—Pistons:
Piston.
Piston-pin.
Piston-pin lock-screw (in connecting-rod or piston).
Piston-ring.
Piston-ring groove.

DIVISION II—VALVES

Group 1—Camshaft:
Camshaft.
Eccentric shaft (Knight engine).
Camshaft timing-gear.
Camshaft timing-gear key.
Camshaft idler gear.
Camshaft oil-pump gear.
Camshaft ignition-distributor gear.
Exhaust cam.
Inlet cam.
Oil-pump eccentric (or cam).

Group 2—Valves:
Valves should be numbered 1 Ex, 1 In, 2 Ex, 2 In, etc., according to the number of the cylinder. On V-type engines the numbers should be 1 REx, 1 LEx, etc.
Poppet valve.
Inlet valve.
Exhaust valve.
Valve-spring.
Valve-spring retainer.
Valve-spring retainer lock.
Valve-lifter.
Valve-lifter guide.
Valve-lifter-guide clamp.
Valve-lifter roller.
Valve-lifter-roller pin.
Valve adjusting screw.
Valve adjusting screw nut.
Valve-rocker (either at cam or at overhead valve; if both, upper and lower).
Valve push-rod (intermediate between lifter and valve in I-head engine).

DIVISION III—COOLING SYSTEM

Group 1—Fan:
Fan.
Stationary fan support.
Adjustable fan support.
Fan hub.
Fan-blades.
Fan pulley.
Fan-belt.
Fan driving pulley.

Group 2—Radiator:
Radiator core.
Radiator shell.
Radiator upper tank.
Radiator right side.
Radiator left side.
Radiator lower tank.
Radiator filler-cap.
Radiator strainer.
Radiator drain-cock.

Group 3—Pump:
Water-pump.
Water-pump impeller.
Water-pump-impeller key.
Water-pump body (in case of doubt, body is member mounted on engine).
Water-pump cover.
Water-pump shaft.
Water-pump gland (part in contact with packing, whether threaded or not).
Water-pump-gland nut (or screw, or other part used to compress gland).
Water-pump shaft gear.

Group 4—Pipes and Hose:
Engine water outlet.
Engine water inlet.
Radiator hose (upper and lower).
Radiator water fitting (upper and lower).
Water-pump outlet pipe.

DIVISION IV—FUEL SYSTEM

Group 1—Carbureter and Inlet Pipe:
Carbureter.
Inlet manifold (more than one connection to cylinder).
Inlet pipe (only one connection to cylinder).
Inlet manifold or pipe gaskets (at cylinders).
Carbureter gasket.

Group 2—Carbureter Control:
(Throttle control rods will take names from parts they connect, shafts by location or arrangement, and brackets by parts they support).
Accelerator pedal.
Accelerator pedal bracket.
Accelerator pedal pin.
Accelerator pedal rod.
Accelerator pedal rod end pin.
Carbureter mixture hand-regulator.
Carbureter choke.

Group 3—Carbureter Air Heater:
Carbureter air heater.
Carbureter hot-air pipe.

Group 4—Fuel Tank:
Fuel tank.
Fuel reserve tank.
Fuel gage.
Fuel gage float.
Fuel gage glass.
Fuel tank outlet strainer.
Fuel tank outlet (flange, fitting, etc.).
Fuel tank pressure flange (or fitting).

Group 5—Fuel Pipes and Feed Systems:
Main fuel valve.
Reserve fuel valve.
Fuel pipe, main tank to auxiliary tank (or names of other parts connected).
Fuel pressure-pump (power pump).
Fuel hand-pump.
Fuel pressure-gage pipe.
Fuel pressure-gage tee.
Fuel pressure pipe to tank.
Fuel pressure pump pipe.
Fuel hand-pump pipe.
Fuel hand-pump tee.
Fuel pressure gage.

DIVISION V—EXHAUST SYSTEM

Group 1—Exhaust Manifold:
Exhaust manifold.
Exhaust manifold gasket.

Group 2—Exhaust Pipe and Muffler:
Muffler.
Exhaust pipe (extends from exhaust manifold to muffler. If in more than one part name sections front and rear. For V-type engines with two pipes name right and left).
Muffler outlet pipe.

DIVISION VI—LUBRICATION SYSTEM

Group 1—Oil-pan or Reservoir:
Oil-pan.
Oil tank (when separate).
Oil-filler strainer.
Oil-filler cap.

Group 2—Oil-pump:
Oil-pump.
Oil-pump body (any type of pump).
Oil-pump plunger.
Oil-pump plunger spring.
Oil-pump inlet valve.
Oil-pump outlet valve.
Oil-pump shaft.
Oil-pump shaft gear (outside the pump).
Oil-pumping shaft gear (inside the pump).
Oil-pumping follower gear.
Oil-pump cover.

Group 3—Oil Pipes, Strainers, Gages:
(Oil pipes should be named from the parts they connect, as "Oil-pump to pressure-gage pipe.")
Circulating-oil strainer.
Oil-strainer cap.
Sight feed.
Sight-feed glass.
Oil level-gage.
Oil level-gage float.
Oil level-gage glass.
Oil pressure-gage.

DIVISION VII—IGNITION

Group 1—Spark-plugs, Cables and Switches:
Spark-plugs.
Spark-plug cables (numbered according to cylinders).
Coil high-tension cable.
(Low-tension cables should be named from the parts they connect, as: "Storage battery to ignition switch cable." In case of more than one conductor the cable should be designated as double, triple, etc.)
Ignition coil.
Ignition switch.
Dry cell (two or more cells make a dry battery).

Group 2—Ignition Distributor:
Ignition-distributor breaker.
Ignition-distributor breaker-arm.
Ignition-distributor breaker-arm point.
Ignition-distributor fixed breaker-point.
Ignition-distributor brush.
Ignition-distributor shaft.
Ignition-distributor shaft gear.

Group 3—Magneto:
Magneto.
Magneto distributor.
Magneto breaker-box.
Magneto breaker-arm.
Magneto fixed breaker-point.
Magneto breaker-arm point.
Magneto distributor brush.
Magneto-collector-ring brush.
Magneto coupling, pump end.
Magneto coupling, center member.
Magneto coupling, magneto end.

Group 4—Ignition Control:
Spark control rod (name parts connected).
(Other control parts named as explained under throttle control.)

DIVISION VIII—STARTING AND LIGHTING EQUIPMENT

A one-unit system uses a starter-generator.
A two-unit system uses a generator and a starting motor.
A combined unit system uses a duplex starter-generator.

Group 1—Generator:
Generator.
Generator brush.
Generator brush-holder.
Generator gear.
Generator shaft.
Generator coupling (members as indicated under magneto coupling).

Group 2—Starting Motor:
Starting motor.
Starting-motor brush.
Starting-motor brush-holder.
Starting-motor pinion.
Starting-motor intermediate gear.
Starting-motor intermediate-gear shaft.
Starting-motor intermediate pinion.
Overrunning clutch.

Group 3—Wiring:
(Cables and conduits should be named from parts they connect.)
Starting switch.
Starting-switch pedal (or lever).

Group 4—Battery:
Storage battery.
Filler cap.
Terminal post.
Connector strip.

DIVISION IX—MISCELLANEOUS ELECTRICAL EQUIPMENT

Group 1—Lamps and Wiring:
Head-lamp.
Tail-lamp.
Side-lamp.
Instrument lamp.
Tonneau lamp.
Dome lamp.
Pillar lamp.
Inspection lamp.
Inspection-lamp cord.
Inspection-lamp plug.
Inspection-lamp socket.
Head-lamp socket.
Head-lamp support.
Head-lamp support tie-rod.
Tail-lamp support.
(Cables and conduits should be named from the parts they connect.)
Junction-box (wires not attached to box).
Junction-box screw.
Junction-box cover.
Fuse-box.
Fuse-box cover.
Fuse-block.
Fuse-clip.
Fuse (designated by name of part fed by circuit).
Junction panel.

Group 2—Switches and Instruments:
Lighting switch.
Ammeter.
Voltmeter.
Volt-ammeter.
Charging indicator.
Reverse current cut-out.
Current regulator.

Group 3—Horn:
(No names have been selected for horn parts.)

Group 4—Miscellaneous:
(Will include any additional electrical equipment, such as electrical gearshift.)

DIVISION X—CLUTCH

General

Plate clutch (one plate clamped between two others).
Disk clutch (more than three disks).
Dry disk clutch.
Lubricated disk clutch.
Cone clutch (leather faced, asbestos faced).
Expanding clutch.

Group 1—Clutching Parts:

Cone Clutch

Clutch cone.
Clutch facing.
Clutch-facing spring.
Clutch-facing-spring plunger.
Clutch spring.
Clutch thrust-bearing.
Clutch cone hub.
Clutch cone bushing.
Clutch-spring spider (for cone clutch with multiple springs).
Clutch-spring stud.
Clutch-spring retainer.
Clutch-spring nut.
Clutch spindle.
Clutch shaft (not attached to crankshaft).
Clutch shaft bearing (not in transmission case).

Disk Clutch

Clutch case (rotating member).
Clutch housing (non-rotating member).
Clutch cover.
Clutch housing cover.
Clutch driven disk.
Clutch driving disk.
Clutch driving disk stud.
Clutch pressure plate (front and rear, if two—used on both disk and plate clutches).
Clutch driven spider (or drum—driving and driven, if two).
Clutch cork-inserts.
(Facing, spring, thrust-bearing, etc., as under cone clutch.)

Plate Clutch

Clutch driven plate.
Clutch driving plate.
Clutch pressure levers.
(Other parts as under cone and disk clutches.)

Group 2—Releasing Parts:
Clutch release sleeve.
Clutch release shoe or clutch release bearing housing.
Clutch release bearing.
Clutch release fork.
Clutch release fork lever.
Clutch release fork shaft.
Clutch pedal shaft.
Clutch pedal adjusting link.
Clutch pedal.
Clutch pedal pad.
Clutch brake.
Clutch brake facing.

DIVISION XI—TRANSMISSION

Group 1—Transmission:
Transmission case (upper half and lower half, if bearings seat in both).
Transmission case cover.
Clutch gear.
Clutch gear bearing (front and rear, if two).
Clutch gear bearing retainer.
Countershaft.
Countershaft front bearing (if ball or roller).
Countershaft front bearing bushing (if plain bearing).
Countershaft front bearing retainer.
Countershaft rear bearing retainer.
Countershaft drive gear.
Countershaft second-speed gear.
Countershaft low-speed gear.
Countershaft reverse gear.
Reverse idler gear.
Reverse idler gearshaft.
Reverse idler gear bushing.
Transmission shaft.
Transmission shaft pilot bearing.
Transmission shaft pilot bearing bushing (if plain).
Transmission shaft rear bearing.
Transmission shaft rear bearing retainer.
Second and high sliding gear.
Low and reverse sliding gear.

Group 2—Shifting Mechanism:
High-gear shift fork.
Low-gear shift fork.
Reverse shift fork (if three are used).
High-gear shift bar.
Low-gear shift bar.
Reverse shift bar.

Group 3—Control:
Gearshift bar selector.
Gearshift lever shaft.
Low gearshift connecting-rod.
High gearshift connecting-rod.
Gearshift hand lever ("hand" may be omitted).
Gearshift hand lever bracket ("hand" may be omitted).
Gearshift housing (center control).
Gearshift gate.

Group 4—Propeller-shaft:
Propeller-shaft.
Propeller-shaft front universal-joint (assembly—"propeller-shaft" may be omitted).
Propeller-shaft rear universal-joint (assembly—"propeller-shaft" may be omitted).
Propeller-shaft front bearing (with inclosed shaft).
Transmission shaft universal-joint flange (substitute name of any other shaft on which flange is mounted).
Universal-joint flange yoke.
Universal-joint slip yoke.
Universal-joint plain yoke.
Universal-joint center cross (ring or block).
Universal-joint bearing bushing.
Universal-joint pin (may be designated as long and short, straight and shoulder, etc.).
Universal-joint inner casing.
Universal-joint outer casing.
Universal-joint casing packing.
Universal-joint casing nut.
Universal-joint trunnion (for trunnion type joint).
Universal-joint trunnion block.

DIVISION XII—REAR AXLE

General Types

Dead Axle—An axle carrying road wheels with no provision in the axle itself for driving them.

Live Axle—General name for type of axle with concentric driving shaft.

Plain Live Axle—Has shafts supported directly in bearings at center and at ends, carrying differential and road wheels.

(The plain live axle is practically extinct.)

Semi-Floating Axle—Has differential carried on separate bearings, the inner ends of the shaft being carried by the differential side gears and the outer ends supported in bearings.

The semi-floating axle shaft carries torsion, bending moment and shear. It also carries tension and compression if the wheel bearings do not take thrust, and compression if they take thrust in only one direction.

Three-Quarter Floating Axle—Inner ends of shafts carried as in semi-floating axle. Outer ends supported by wheels, which depend on shafts for alignment. Only one bearing is used in each wheel hub.

The three-quarter floating axle shaft carries torsion and the bending moment imposed by the wheel on corners and uneven road surfaces. It also carries tension and compression if the wheel bearings are not arranged to take thrust.

Full-Floating Axle—Same as three-quarter floating axle, except that each wheel has two bearings and does not depend on shaft for alignment. The wheel may be driven by a flange or a jaw clutch.

The full-floating axle shaft is relieved from all strains except torsion, and in one possible construction, tension and compression.

Types of Axle Drive

The different types of live axle can be driven by *Bevel Gear, Spiral Bevel Gear, Worm, Double-Reduction Gear* or *Single Chain.*

In other constructions the rear wheels are driven by *Double Chains, Internal Gears* or *Jointed Cross-shaft.*

Group 1—Housing:
Rear-axle housing (if one piece).
Right and left halves (if two pieces).
Bevel (or worm) gear housing } (if three pieces)
Right rear-axle tube } (if three pieces)
Left rear-axle tube } (if three pieces)
Rear-axle-housing cover.
Differential carrier (bolted to housing).
Rear-axle spring-seat.
Axle brake-shaft bracket (right and left).
Wheel brake-support, right and left ("wheel" may be omitted).
Wheel brake-shield ("wheel" may be omitted).

Group 2—Torque Arm and Radius Rod:
Radius rods.

Group 3—Drive Pinion:
Axle drive bevel pinion (or worm).
Axle drive pinion (or worm) shaft.
Axle drive pinion front bearing.
Axle drive pinion rear bearing.
Axle drive pinion thrust-bearing.
Axle drive pinion front bearing adjuster.
Axle drive pinion front bearing adjuster lock.
Axle drive pinion rear bearing adjuster.
Axle drive pinion rear bearing adjuster lock.
Axle drive pinion adjusting sleeve (containing both bearings).
Axle drive pinion (or worm) carrier.

Group 4—Differential:
Axle drive bevel (or worm) gear.
Differential.
Differential case, right.
Differential case, left.
Differential side gear.
Differential spider pinion ("spider" may be omitted).
Differential spider (or pinion shaft).
Differential bearing.
Differential thrust-bearing.
Differential bearing adjuster.
Differential bearing adjuster lock.

Group 5—Axle Shafts:
Axle shaft (right and left).
Axle shaft wheel-flange (or clutch).

DIVISION XIII—BRAKES

General

In the following list of brake parts the terms "outer" and "inner" are used, being applicable to any case of two sets of brakes on the rear wheels. Where the brakes are external and internal these terms may be substituted for "outer" and "inner." Where one brake is located at the wheels and the other at the transmission the terms "wheel brake" and "transmission brake" should be substituted. With other concentric or side-by-side brakes the terms "outer" and "inner" should be retained, "outer" indicating in the latter case the ones nearer the wheels.

The list is made up for external contracting and internal expanding brakes. If both brakes are of one type the necessary changes will be obvious. The designation of brake parts on the rear axle as foot-brake or hand-brake parts, or by equivalent terms, is too remote to be clear, especially in the case of stock axles whose brakes may be connected either way according to chassis design. Nearly the same condition prevails in regard to designating parts on the chassis according to whether they are connected to the inner or outer brakes at the axle.

The terms "service brake" and "emergency brake" should not be used. Better designations are "foot brake" and "hand brake"; or if both brakes foot-operated, "right foot-brake" and "left foot-brake."

Group 1—Outer Brake:
Outer brake band.
Outer brake band lining.
Outer brake band adjusting nut (yoke, etc.).
Outer brake hand lever.
Outer brake lever shaft.
Outer brake shaft inner end lever.
Outer brake shaft outer end lever.

Group 2—Inner Brake:
Inner brake shoe (or band).
Inner brake shoe (or band) lining.
Inner brake toggle (link, etc.).
Inner brake toggle lever.
Inner brake toggle shaft.
Inner brake cam.
Inner brake camshaft.
Inner brake camshaft (or toggle shaft) lever.

Group 3—Pedal (or outer) Brake Control:
Outer brake rod.
Outer brake rod yoke.
Outer brake intermediate shaft (or tube)—right and left.
Outer brake intermediate shaft (or tube)—right lever.
Outer brake intermediate shaft (or tube)—left lever.
Outer brake intermediate shaft (or tube)—center lever.
Outer brake right equalizer lever.
Outer brake left equalizer lever.
Outer brake equalizer.
Brake pedal.
Brake pedal rod.
Brake pedal rod yoke.
Brake pedal pad.
Brake pedal shaft.

Group 4—Hand (or inner) Brake Control:
Inner brake rod.
Inner brake rod yoke.
Inner brake intermediate shaft (or tube)—right and left.
Inner brake intermediate shaft (or tube)—right lever.
Inner brake intermediate shaft (or tube)—left lever.
Inner brake intermediate shaft (or tube)—center lever.
Inner brake right equalizer lever.
Inner brake left equalizer lever.
Inner brake equalizer.
Brake hand lever rod.
Brake hand lever rod yoke.
Brake hand lever.
Brake lever segment (or sector).
Brake lever pawl.
Brake pawl spring.
Brake pawl button.
Brake pawl finger lever.
Brake pawl rod.

DIVISION XIV—FRONT AXLE AND STEERING

Group 1—Axle Center.
Front axle center.
Front spring seats.
Front axle bushing.

Group 2—Steering Knuckles:
Right steering-knuckle.
Left steering-knuckle.

Steering-knuckle bushing (upper and lower).
Steering-knuckle pivot.
Steering-knuckle pivot nut.
Steering-knuckle thrust-bearing.
Right steering-knuckle arm.
Left steering-knuckle arm.
Steering-knuckle gear rod arm.

Group 3—Steering-rods:
Steering-knuckle tie-rod.
Steering-knuckle tie-rod end.
Steering-knuckle tie-rod clamp bolt.
Steering-knuckle tie-rod pin.
Steering-gear connecting-rod.

Group 4—Steering-gear:
Steering-gear case.
Steering-gear-case cover.
Steering-gear bracket.
Steering-gear arm.
Steering-arm shaft (if separate from sector or other operating member).
Steering-wheel rim.
Steering-wheel spider.
Steering-wheel tube (or shaft).
Spark and throttle sector.
Spark and throttle sector tube.
Spark hand-lever.
Spark hand-lever tube (or rod).
Throttle hand-lever.
Throttle hand-lever tube (or rod).
Steering-column tube (stationary).
Steering-column cowl (or dash or floor) bracket.

The various bushings in the steering-column take names from parts to which they are permanently fitted, being further distinguished as upper and lower, inner and outer, if necessary. Bushings in the steering-gear case take names from the worm and sector or other main operating parts which they support, as steering-gear worm upper bushing, although the steering-wheel tube may be the member which turns inside the bushing.

Steering worm
Steering-worm sector (or gear)
Steering-worm shaft
} (worm and sector gear)

DIVISION XV—WHEELS

Group 1—Front Wheels:
Front wheel felloe.
Front wheel felloe band.
Front wheel rim.
Rim bolts.
Rim clamps.
Front wheel hub.
Front wheel hub flanges.
Front wheel hub-cap.
Front wheel outer bearing.
Front wheel outer bearing inner race.
Front wheel outer bearing outer race.
Front wheel outer bearing balls.
Front wheel outer bearing ball retainer.
Front wheel outer bearing rollers.
Front wheel outer bearing roller cage.
Front wheel inner bearing (parts same as outer bearing).
Front wheel bearing spacer.
Front wheel bearing nut.
Front wheel bearing lock nut.
Front wheel bearing locking washer.

Group 2—Rear Wheels:
Rear wheel hub.
Rear wheel hub-flange.
Rear wheel hub-cap.
Rear wheel outer bearing.
Rear wheel inner bearing.
Wheel brake-drum.
(Other parts named like front wheel parts.)

DIVISION XVI—FRAME AND SPRINGS

Group 1—Frame:
Frame side member (right and left).
Front cross member.
Rear cross member.
Center cross member.
(As above if only three cross members; as below if more than three.)
First cross member.
Second cross member, etc.
Sub-frame side member (right and left).
Sub-frame cross member (front and rear).
Right rear gusset (upper and lower).
(Gussets at other cross members named according to member.)

Group 2—Frame Brackets and Sockets:
Front spring front bracket (right and left).
Front spring rear bracket (right and left).
Rear spring front bracket (right and left).
Rear spring rear bracket (right and left).
Running-board bracket (front, right, etc., if not duplicates).
Running-board bracket brace.
Engine front support bracket.
Engine rear support bracket.
Torque-arm bracket.
Radius-rod bracket.

Group 3—Front Springs:
Front spring (right and left).
Front spring shackle.
Front spring shackle-bolt (upper and lower).
Front spring front bolt.
Front spring rebound-clip.
Front spring seat.
Front spring seat pad.
Front spring clip.
Front spring clip plate.
Front spring center-bolt.

Group 4—Rear Springs:
Rear springs (upper and lower for elliptic and three-quarter elliptic).
Rear spring pivot bolt (or pin)
Rear spring pivot seat
} (for half-elliptic cantilever spring)
Rear spring double shackle
Rear side spring
Cross spring.
} (for platform spring)
(Other parts as for front springs.)

DIVISION XVII—HOOD, FENDERS AND SHIELDS

Group 1—Hood:
Hood.
Hood sill.
Hood handle.
Hood fastener.
Hood fastener bracket (spring, lever, etc.).

Group 2—Engine Shield:
Engine shield.
Engine shield fastener.
Engine shield bracket (spring, etc.).

Group 3—Fenders and Running-boards.
Running-board (right and left).
Running-board linoleum coverings.
Running-board outside binding.
Running-board inside binding.
Running-board front binding.
Running-board rear binding.
Running-board shield (right and left).
Right front fender.
Left front fender.
Right rear fender.
Left rear fender.
Fender support socket.
Right front fender front support.
Right front fender rear support.
(Other fender supports accordingly.)

Group 4—Windshield:
(Names for windshield parts have not been selected.)

DIVISION XVIII—BODY

Types of Bodies

Roadster—An open car seating two or three. It may have additional seats on running-boards or in rear deck.

Coupelet—Seats two or three. It has a folding top and full-height doors with disappearing panels of glass.

Coupe—An inside operated inclosed car seating two or three. A fourth seat facing backward is sometimes added.

Convertible Coupe—A roadster provided with a detachable coupe top.

Clover Leaf—An open car seating three or four. The rear seat is close to the divided front seat and entrance is only through doors in front of the front seat.

Touring Car—An open car seating four or more with direct entrance to tonneau.

Salon Touring Car—A touring car with passage between front seats, with or without separate entrance to front seats.

Convertible Touring Car—A touring car with folding top and disappearing or removable glass sides.

Sedan—A closed car seating four or more all in one compartment.

Convertible Sedan—A salon touring car provided with a detachable sedan top.

Open Sedan—A sedan so constructed that the sides can be removed or stowed so as to leave the space entirely clear from the glass front to the back.

Limousine—A closed car seating three to five inside, with driver's seat outside, covered with a roof.

Open Limousine—A touring car with permanent standing top and disappearing or removable glass sides.

Berline—A limousine having the driver's seat entirely inclosed.

Brougham—A limousine with no roof over the driver's seat.

Landaulet—A closed car with folding top, seats for three or more inside, and driver's seat outside.

Group 1—Floor-boards and Dash:
Floor-boards (horizontal).
Toe-boards (sloping).
Heel-boards (under seats).
Dash (separates engine compartment from driver's compartment).
Instrument board.

Group 2—Body.*

Group 3—Upholstering.*

Group 4—Top.*

DIVISION XIX—ACCESSORIES

Group 1—Speedometer.*

Group 2—Tire-pump:
Tire-pump.
Tire-pump driving gear.
Tire-pump shaft gear.
Tire-pump idler gear.

*Names for parts in these groups have not been selected.

Klaxon Horn Warns of Gas Attacks

AT the left is a reproduction of a photograph of a listening post at the front in France. This photograph was brought to this country by William R. Fay, of the American Ambulance, who explains the listening post as being a point in the first line trenches nearest to the enemy. These posts are manned by volunteers as the work is extremely dangerous, the posts sometimes being only a few feet from the enemy parapet. The duty of the men is to warn the defending forces of impending gas attacks. In this connection an interesting use of automobile horns is made, each post being equipped with a Klaxon as shown in the illustration, the roar and rattle of shell and machine gun fire rendering a sharp, clear-cut warning note necessary, while a man's voice is absolutely lost in the clamor. The piece of sheet steel mounted over the horn is for the purpose of protecting it from shrapnel fire. When the trench defenders hear the horn shriek they throw on their gas masks and are in readiness.

Fuel Commonsense

OF all proverbs the most true is that which says "a little knowledge is a dangerous thing." In this age when everyone has a smattering of scientific knowledge the public at large is a ready prey for the charlatan who can reel off a quasi-scientific tale. Even now in the twentieth century there are thousands of well educated people who are not aware of the impossibility of perpetual motion. The patent office has not yet ceased to have applications for thousands of machines that cannot ever operate. Thus when the claim is made that some liquid has been discovered of which a few drops will render water combustible there are plenty of persons to be found who fail to grasp the absolute scientific impossibility of the feat.

To do this would be the exact equivalent of turning ashes back into the coal from which they were formed, the equivalent of making bodies fall upward instead of downward.

Might Act as Carrier

There is only one way in which a water mixture could possibly serve as fuel and it is a way that is highly improbable to say the least. It is just conceivable that some high explosive, containing an immense amount of potential chemical energy might be dissolved in water and then burned while in suspension in a mist of spray, converting the water into steam. That such a solution would be capable of ignition by an ordinary sparking plug, or that it could be carbureted in the conventional way is almost as improbable as that such a solution could be made in the first place. Incidentally, it may be added, science has never yet discovered a cheap explosive, and that a few drops of liquid containing as much energy as a corresponding number of gallons of gasoline would be an explosive so powerful that its manufacture would be both difficult and dangerous.

The Laws of Energy

Scientific progress has taught us that what seems highly improbable to-day may be simple enough to-morrow, but the laws of energy remain the same as they have always been. Scientists know every substance from which the earth is made and they know the exact amount of energy which is available by burning those substances in the atmosphere. Science also knows how to make many other substances which will burn with much greater liberation of energy, but the making of the latter necessitates the expenditure of energy. In other words science has never discovered how to get more energy out of a substance than was put into it originally and the common fuels used by man contain the greatest amounts of natural or inherent energy. All our fuels are vegetable products containing the energy of the sunlight which shone upon them millions of years ago.

Thus while few things are utterly impossible, many are so improbable that they approach impossibility. Any liquid which would do what is claimed for the water energizer would not only solve the gasoline problem, it would revolutionize the entire artificial heat and power system of the world.

Important Trade News

IN this, and future issues of THE AUTOMOBILE the leading events of the week will be dealt with on the first few pages instead of in the center of the paper as hitherto. Trade news of lesser importance will conclude the editorial section, while all the articles and the regular features will form the center. We believe that very many of our readers turn to the news pages first of all and the latter will now be more readily accessible.

Better Work Wanted

WHILE there is no doubt that some of the cheapest of automobiles are well and carefully made, there is no doubt that a good many thousands of machines have been sold in the last few months which were really unfit to go into the hands of the user. Throughout the country there has been considerable complaint regarding the accuracy of fitting and assembling and, though the owner or dealer does not expect perfection of workmanship in an admittedly cheap car, he does not expect to have to overhaul the engine bearings after 500 miles of running. Some reputations are suffering.

$16,213,387 in Fees for Roads

This Is 90% of Total Collected in United States in 1915

WASHINGTON, D. C., July 3—Ninety per cent of the registration and license fees paid in 1915 by automobilists to the States, or $16,213,387, was spent for the building and maintenance of county and State roads, according to a compilation just published by the Office of Public Roads, U. S. Department of Agriculture. In all, 2,445,664 motor vehicles were registered in that year and their owners paid a total of $18,245,713 for registrations and drivers' and dealers' licenses. This is an increase of $5,863,760 over 1914, and an increase of 734,325 in the number of vehicles registered. Automobile fees now defray nearly 7 per cent of the total amount spent on rural road and bridge building, whereas in 1906 the income from this source was less than three-tenths of 1 per cent of the total expenditure.

Rapid Growth in Registration

The growth of the volume of fees and registrations is noted by the fact that in 1901 New York, the first State to require fees, collected only $954. In 1906 only 48,000 cars were registered throughout the entire United States. By 1915, however, the number had jumped to the figure given, so that there is slightly more than one motor car registered for each of the 2,375,000 miles of road outside of the incorporated towns and cities.

The relation between cars and road mileage varies widely in different sections. There is only one car for every 6 miles of rural road in Nevada, but nearly six cars for every mile of such road in New Jersey. There is an average of one car registration for every forty-four persons in the United States. Iowa apparently leads, however, with one car for every sixteen persons, while only one for every 200 persons is registered for Alabama.

It must be understood, however, that the figures of registration do not necessarily represent a total number of cars, as some of the States do not require annual registration, others group pleasure and commercial cars and motor cycles in their accounts, while still other States do not require registration of motorcycles.

There is great inequality in the registration fees charged by the different States. The average for the United States was $7.46. The State of Vermont, however, secured in 1915 a gross revenue of $18.10 for each car, while Minnesota received only about 50 cents annually for each car. In Texas and South Carolina no annual registration fees are collected, the only requirement being a county fee of 50 cents and $1 respectively for perennial registration. Most of the States, however, also levy annual taxes on motor vehicles and this adds importantly to the public revenue contributed by the owners of motor-propelled vehicles.

In the use of fees, however, there seems to be a general policy of applying the major part of the money collected from automobilists directly to road betterment. In forty-two of the States of the Union all or the major portion of the motor-vehicle revenue must be expended for the construction, improvement, or maintenance of the public roads, or for the maintenance of the State highway department. In twenty States, all or the major portion of the net motor vehicle revenues are expended by or under the supervision or direction of the State highway department. In seven States one-half to one-fourth of the State motor vehicle revenues are expended through the State highway department, and the remainder by the local authorities. Many States, in addition to applying license fees to road construction expend for this purpose a large part of the fines and penalties collected from owners.

California Leads in Fees

In the number of registrations New York State led in 1915 with 255,242; Illinois was second with 180,832; California third with 163,797; and Pennsylvania fourth with 160,137. In gross revenues received from this source, however, California led with $2,027,432; New York was second with $1,991,181; Pennsylvania third with $1,665,276; while Iowa, with 145,000 cars registered, came fourth in point of revenue with $1,533,054.

—

Cole Adds All-Weather Body

INDIANAPOLIS, IND., July 1—The Cole Motor Car Co., this city, has mounted an all-weather body on its eight-cylinder chassis. The Cole-Springfield body, as it is known, sells at $2,195. The car is called the Cole-Springfield Toursedan.

There are two other Cole models equipped with the new body. One is known as the Tourcoupé, selling for $2,195, and the other is the Towncar listed at $2,495.

The body is finished in American flag blue with dull block trimming and mouse gray upholstering. It has automatic electric door lights, which switch on and off as the doors are opened and electric light switches are located both at the driver's seat and in the tonneau.

The company will continue its standard eight, seven-passenger touring car and four-passenger Tuxedo roadster, which continue to sell for $1,595.

British Bar U. S. Cars July 16

Importation of American-Built Trucks Is Also More Closely Restricted

LONDON, ENGLAND, June 30—*Special Marconigram* to THE AUTOMOBILE:—The British Government has further restricted the importation into the United Kingdom of automobiles and commercial vehicles, which is to go into effect on July 16. Provision is made for the importation under licenses issued by the Government of such articles as may be approved by the authorities.

After July 16 the importation into the United Kingdom of such automobiles, trucks, chassis, parts and accessories, except tires, as were exempted from previous prohibition will be prohibited. Licenses to import such goods will be granted where goods were en route or were paid for on the date of the proclamation. Licenses for the importation of automobiles will be issued where the national interest is apparent or where trucks are required for fire departments, conveyances for wounded or sick, for police or local government authorities, agricultural purposes, or the conveyance of essential goods. Spare automobile parts may be imported under license when intended for imported commercial vehicles already in the United Kingdom.

A general license has been issued permitting the unrestricted importation of steel ball bearings and tool handles.

Fighting American Competition

This action, presumably by the Chancellor of the Exchequer, Reginald McKenna, culminates a long series of efforts on the part of the British trade to prevent further American competition. Tied up with government orders to such extent that they could not supply private users and later released to some extent for private trade with government contractors, British factories have been unable to supply British business men with motor delivery and haulage equipment. There are now some thirty lines of American trucks represented in England. Recently a number of releases of product for private sale were granted some of the truck firms which have since been withdrawn, so that with the demand for trucks greater than ever before and the home-manufactured product still largely taken up by the government, British business is to be forced by the government to put up with inferior equipment or no equipment at all lest American trucks secure too firm a foothold in the British market.

This action on the part of England tallies closely with that of France, which

has put a ban on all motor vehicles not ordered before May 8. An attempt is being made to exempt trucks from this drastic measure, as was successfully done at the time of the passage of the prohibitive tariff on motor vehicles in England; but the French effort is not apt to prove effective since the government is willing to rent trucks to government contractors as they may be required. They will be able to provide all of the vehicles that will be needed, since they can be purchased from America by the government. This will give the government of France complete control of the situation, so that the number of American trucks required to carry on the war will be sufficient and yet American enterprise will be prevented from securing a place in the French market.

—

Republic Truck Co. Adds $1,000,000 to Its Capital

ALMA, MICH., June 30—The Republic Motor Truck Co., has increased its capital $1,000,000, the former capital being $250,000. The company recently bought a large tract of land in this city and the cash increase will be used to improve this tract and triple the capacity of the plant. It has contracted for materials to build 18,000 trucks for 1917.

—

Cummins Monitor Capital $100,000

COLUMBUS, OHIO, July 1—The Cummins Monitor Co., this city, has increased its capital to $100,000.

—

Few Market Changes

NEW YORK CITY, July 3—The automobile materials market last week remained steady, with few price changes. Aluminum went down 3 cents a lb. to 60.

With the War Department taking bids on over 5000 trucks for immediate delivery to the Mexican border, the manufacturers in the West are urgently seeking to cover their requirements against prospective contracts. Several of the companies have sounded mills on steel for frames, taking material out of stock. One Western automobile plant has already secured a contract for 1500 trucks from the U. S. Government and placed a rush order for 4 and 6-in. channels.

Day and Warner on G. M. Board

—

General Managers of G. M. Truck Co. and Oakland Complete Directorate

DETROIT, MICH., July 3—Following a policy of having the various units of its organization as representative as possible on the board of directors, the General Motors Co., at a meeting in New York on June 27, elected W. L. Day, general manager of the General Motors Truck Co., and Fred W. Warner, general manager of the Oakland Motor Car Co., both at Pontiac, Mich., to the board of directors. These elections filled vacancies occasioned by the resignations on June 1 of three members of the banking interests that had aided in tiding the organization over its period of depression some years ago.

Fill Vacancies

Those resigning at the time of the election of W. C. Durant to the presidency to succeed C. W. Nash, were Albert Strauss of J. & W. Seligman & Co., J. J. Storrow of Lee, Higginson & Co., both of New York, and Emory W. Clark, head of the First and Old Detroit National Bank of Detroit. To fill one of these vacancies on the board, W. C. Leland, vice-president and general manager of the Cadillac Motor Car Co., was elected at the June 1 meeting, and Day and Warner have now completed the directorate.

Both Implement Men

Both Day and Warner are old farm implement men, who, like many others in the industry, graduated to the automobile business after long years of experience in the other line. Day came to the truck unit in 1912, leaving the Mitchell-Lewis Motor Co., where he was general manager. Before his connection with the latter concern he had been for 27 years general manager of the Parlin & Orrendorff Plow Co. at Kansas City. Warner 2 years ago took up the Oakland management, coming from Chicago, where he had managed the Buick branch. Prior to his connection with Buick he had long been connected with the John Deere Plow Co., also at Kansas City. Both men have made a striking success of the General Motors units they are now managing.

—

Willys-Overland Earns $4,377,799 in 4 Months

NEW YORK CITY, June 30—The Willys-Overland Co. reports to the local stock exchange for the 4 months ended April 30, 1916, net earnings all companies, $4,377,799; interest on floating debt, $184,655; surplus, $4,193,144.

The $1,500,000 Willys-Overland common stock which has just been listed on the Stock Exchange is the stock which was specifically reserved for that purpose when the authorized capitalization was increased by action of the stockholders last January.

Practically all of this $1,500,000 common stock has been allotted to employees, and is to be paid for in monthly instalments over a period of 10 years. No stock is to be delivered to the employees until all payments are completed, thus requiring 10 years before this stock is to be delivered.

—

Diamond 300% Cash Dividend

DETROIT, MICH., July 1—The Diamond Mfg. Co., one of the Detroit concerns that was recently taken over by the Motor Products Corp., of which W. H. Rands is president, is now paying its stockholders a 300 per cent cash dividend as a result of the change of control. In a letter to the stockholders it is explained that additional cash dividends will be forthcoming and that each will receive pro rata stock in the Motor Products Corp. The Diamond company had a capital stock of $300,000, of which two-thirds was outstanding.

—

Continental Pays 5 per Cent on Common

DETROIT, MICH., June 29—At a meeting of the directors here to-day the Continental Motors Co. declared an initial cash dividend of 5 per cent, payable July 15 to common stock of record July 5.

—

Autocar Co. Increases Capital to $1,800,000

ARDMORE, PA., June 30—The Autocar Co., this city, has declared a cash dividend of 5 per cent., payable to-day, and has also increased its paid-in capital from $300,000 to $1,800,000.

—

Stutz Stock All Purchased

NEW YORK CITY, June 30—The Stutz Motor Car Co. of America, which was recently organized by A. A. Ryan and associates, has completed the purchase of

all the stock of the Stutz Motor Car Co. of Indiana.

The company is planning a larger output. In 1912 it produced 266 cars; in 1915, 1079, while for the 5½ months ended June 15 the output was 874 cars.

Within 4 or 5 weeks the new plant, which is as large as the existing factory, will be in operation. At the present rate, it is estimated that the company will earn in 1916 at least $750,000, which will be available for dividends, amounting to $10 a share on its 75,000 shares of stock, no par value.

H. C. Stutz remains president. The refinancing has brought in new blood, including, A. A. Ryan, G. H. Saylor, S. A. Fletcher and others.

—

Hare, Packard New York Sales Manager

NEW YORK CITY, June 29—E. S. Hare has been appointed manager of sales of the Packard Motor Car Co. in this city, under E. B. Jackson, president of the company. Mr. Hare comes from Philadelphia. From 1909 to 1916 he was vice-president of the Commercial Truck Co. of America, Philadelphia, and joined the Packard organization Jan. 1, 1916, as a special representative of the motor truck department.

—

Dividends Declared

White Motor Car Co., initial quarterly of 87½ cents a share, par value $50, payable July 15 to stock of record July 6. This places the stock on 7 per cent basis.

Swinehart Tire & Rubber Co., quarterly 1½ per cent, payable July 1. Books closed June 26.

Automobile Issues Are Active

—

Willys-Overland on $25 Par Basis—Stutz Reaches New High of 60⅞

NEW YORK CITY, July 3—Automobile issues last week were fairly active with few important changes. The stock of the Stutz company advanced to the new high price of 60⅞ on Friday. At this figure it was nearly 6 points above the figure at which subscriptions were received about 2 weeks ago.

United Motors went up 3 points on reports that interests identified with the property declared current earnings are at the rate of $12 a share on the outstanding stock, and that the management has in mind the payment of quarterly dividends at the rate of $6 a share early in October.

Overland Common High

Trading in Overland common began last week with the stock on a $25 par basis. It opened around 69 and later sold above 72.

Several of the issues on Saturday saw declines. Studebaker sold below 133 as against 137¼ for Friday; Maxwell common dropped to 79½, off 2⅝ points.

Peerless came into prominence after a long period of inactivity, and sold at 26 and 27, a gain of 2 points.

Studebaker common was one of the weak issues last week with a drop of 24¼ points. No reason is given for the drop as the company has just made a very favorable report as to the sales during the first 6 months this year, which amounted to 36,700 cars against 20,400 for the same period of 1915, a gain of 16,300 cars, or 80 per cent.

One more issue has been put on the Stock Exchange. The Ajax Rubber Co. stock has had admittance to the Exchange to the value of $4,000,000.

—

Harry Newman Appointed Chalmers Distributor in Chicago

CHICAGO, ILL., July 3—*Special Telegram.*—Harry Newman, Inc., distributor of Chalmers cars in Wisconsin, northern Michigan and southeastern Minnesota since Dec. 1, 1915, has been appointed Chicago distributor. Distributing stations will be established in Springfield and Chicago. Contracts have been made with the Chalmers company to supply the new distributor with 5000 cars during the fiscal year ending July 1, 1917, which represents a season's business in excess of $6,000,000.

—

Ford Holds Sales Conference

DETROIT, MICH., July 1—The annual sales conference of the Ford Motor Co. has been in progress here this week, managers and assistant managers of the twenty-eight branches of the company in the United States, and of the fifty-one sales and service branches throughout the country being in attendance. These men are responsible to a large extent for the marketing of 500,000 Ford cars for the present fiscal year which ends July 31, and on them will depend a great deal

of the success of the contemplated marketing of 1,000,000 Fords for the next fiscal year. Somewhat over 500,000 cars will have been built when the present year ends, probably being in the neighborhood of 560,000.

—

New Record of 28,500 Goodyear Tires in 1 Day

AKRON, OHIO, June 30—The Goodyear Tire & Rubber Co., this city, on June 22 established a new production record of 28,500 tires, the best previous known record being 18,000 tires in a single day.

The company has 13,000 employees working in three shifts of 8 hr. To achieve the record run the company for 1 day put on a 12-hr. shift so as to utilize 6700 employees on each shift.

A year ago the company was producing about 12,000 tires on the daily average. Last month the gross sales were in excess of $6,000,000 and the total for the month will exceed $7,000,000.

—

Gearless Differential Reduces Prices

DETROIT, MICH., July 3—The Gearless Differential Co., this city, has reduced the price of its replacement differential on Ford and Chevrolet 490 models from $20 to $15; and on its Overland model from $25 to $20.

The company has reduced the cost of manufacturing on account of a much larger manufacturing schedule and the fact that it has been able to standardize many of the parts for the above models for the car and axle makers.

Overland Buys Out Leavitt

Deal with Pacific Coast Distributor of Co.'s Products Involves $1,000,000

LOS ANGELES, CAL., June 30—The J. W. Leavitt & Co. organization is no more. The entire holdings of the company, which has distributed Willys-Overland products on the Pacific Coast, have been purchased by Willys-Overland, Inc., of Toledo. The deal involves practically $1,000,000 cash and is one of the most talked of changes in the automobile industry on the Pacific Coast in years. It is the first time that a factory has purchased an agency from a Pacific Coast dealer or distributor.

The new organization will operate in the form of two companies. The interests in California are to be known as the Willys-Overland of California and those in the Northwest as the Overland-Pacific, Inc.

—

Stutz Features Newark Race

NEWARK, N. J., July 4—J. W. Dickinson in his Stutz Special again carried off the honors at the ½-mile dirt track meet held to-day at Olympic Park, this city. The ½-mile record of 37 2/5 sec., made by him on June 17 last, was shattered when both he and I. C. Barber of Washington, D. C., in an Eye See Bee Special, made the distance in 35 2/5 sec.

To-day's races were featured by closely contested events, the entry list including such cars as Jessop's Chevrolet, Gouirand and Moore's Mercers; and an Adams Special. The last named car, which had raced during the early part of the afternoon at the Sheepshead track, arrived near the closing of the local meet, and managed to participate in a special 3-mile race with Dickinson's Special and the Eye See Bee. The Stutz was put out on account of a punctured tire and the Adams Special just managed to beat the Eye See Bee.

A new 3-mile mark was hung up by Dickinson when he beat the old mark of 3:54 2/5 sec. by 15 sec., his time being 3:39 2/5.

—

Commercial Preparedness Keynote of Studebaker Dealers' Convention

DETROIT, MICH., July 1—Practically every eastern Studebaker dealer in the territory of the New York, Boston, Philadelphia and Norfolk, Va., branches attended the series of conventions held at these branches last week and part of the week before. The conventions were conducted by L. J. Ollier, vice-president and director of sales of the Studebaker Corp.; R. T. Hodgkins, general sales manager; H. A. Biggs, of Frank Seaman, Inc., advertising counsel, and C. F. O'Meara, efficiency expert.

Realizing that it would work a hardship on dealers to ask them to visit the factory at this time of the year, the

De Palma Wins Twin City 150-Mile Race

—

(*Continued from page* 1)

Fourteen cars rolled across the tape for the start. Chevrolet had the pole, and his neighbors were Aitken, De Palma and Christiaens. In the second batallion were Rickenbacher, O'Donnell, Anderson and Galvin. The third row included Milton, Buzane, Henderson and Osteweg, and Sorenson and Muller brought up the rear. Cooper broke a connecting-rod in the trials and did not start.

The real fight for first money was between the first four until Chevrolet dropped out with a broken rocker arm at the end of the fifty-second mile. Christiaens, who led at the start, finished third. De Palma, who started second, ended first. Aitken, who was third, finished second. Milton, a local celebrity, gathered in fourth money and made a strong run. O'Donnell was fifth; Sorenson, local entrant, was sixth, and Muller seventh. Christiaens made a good race with De Palma. They were neck and neck at the end of the third lap and at 10 miles crossed the wire together. De Palma led in the sixth lap; up to the eighteenth Christiaens led by a good margin; then De Palma took the lead. Rickenbacher, who ran third, after the second lap had worked up to second place by steady driving and in the twenty-sixth lap jumped to the lead. This was notwithstanding a blow-out as Rickenbacher rounded the first quarter at 20 miles.

De Palma resumed the lead in the thirtieth lap, after a record of 93.30 miles average for the first 60 miles. Aitken made his way to the front in the thirty-eighth and held it for the next 6 miles, when he was nosed out by De Palma. Christiaens jumped back to the lead for two laps, and then Rickenbacher took the van for 22 miles. The lead then seesawed between Aitken and De Palma, Aitken dropping out in the sixty-ninth lap from tire trouble. Milton ran along about tenth place until he had covered nearly 50 miles, when he began to spurt up to third place. He ran steadily third and fourth until he had tire trouble in the fifty-third round. After 10 miles he dropped out again. For 6 miles he had a neck-and-neck brush with De Palma.

Rickenbacher dropped out at the end of 116 miles, leaving the fast field to De Palma, Aitken and Christiaens. Osteweg withdrew at the end of 30 miles, Galvin at the end of 42 miles. Henderson had 118 miles to his credit when the flag fell and Buzane ran only 138 miles.

De Palma used Mercedes carbureted and shock absorbers, Eisemann plugs, Bosch magneto and Monogram oil. Aitken used Miller carbureter, K. L. G. plugs, Oilzum and castor oil, Rudge-Whitworth wheels and Bosch magneto. Christiaens used Miller carbureter, K. L. G. plugs, Rudge-Whitworth wheels and Bosch magneto. Milton used Zenith carbureter, Rajah plugs, Oilzum, Rudge-Whitworth wheels and Bosch magneto. All the cars in the race used Bosch magnetoes except Muller's Dans L'Argent, which used Delco ignition. All but De Palma's Mercedes used Dixon's graphite and Hartford shock absorbers. All used Motometers except Milton, O'Donnell and Muller.

factory officials came from Detroit to tell them of the company's plans for the year.

Commercial preparedness was the keynote of the gatherings at the eastern cities. A warning was sounded to dealers against any tendency to treat the immediate future as a period of easy sailing simply because the demand for automobiles at this time exceeds anything experienced in the past. It was pointed out that increased production will demand increased selling activity.

100,000 Cars Planned

Announcement was made to the dealers by Vice-president Ollier that the Studebaker Corp. plans a production of 100,000 cars beginning July 1. Sales for the past 12 months have been double those in any similar period, and practically another doubling of sales for the coming 12 months over the period just closing is provided to take care of the greater output. Information was given to the dealers regarding the factory's plans for selling the increased production of cars.

Perfection Spring in U. S. Service

CLEVELAND, OHIO, July 5—The Perfection Spring Co. has been appointed by Secretary of War Baker responsible for the maintenance of the spring equipment on all United States government trucks in use in the Mexican campaign. E. O. Blanchard, president of the Perfection service station in this city, has left for the front in charge of the work for the local company.

—

Rain Postpones Sioux City Race

SIOUX CITY, IOWA, July 4—*Special Telegram.*—A 3-hour cloudburst which visited this city early this morning transformed the local speedway into a pasty mass of mud and made necessary postponement of the Independence Day race meet until Saturday of this week. A number of the drivers disagreed on the time of postponement and the result was that several entrants withdrew their cars Dissatisfaction has been expressed among the drivers concerning the method of prize distribution without a stipulated guarantee. The arrangement here this year calls for a percentage division of the gate receipts among the winners. Several drivers have stated that they would refuse to appear again under similar conditions.

—

Tacoma Races Cancelled

TACOMA, WASH., July 4—*Special Telegram*—The match race for the Northwest Championship at this city to-day was cancelled in the third lap, when Parsons went out with a broken connecting-rod.

1916 Gasoline Output Is Record

140,000,000 Bbl. Marketed in First 6 Months, It Is Estimated

WASHINGTON, D. C., July 1—Some illuminating figures regarding the quantity of petroleum marketed in the United States during the first half of 1916 have been prepared by John D. Northrop, of the United States Geological Survey. He estimates that 140,000,000 bbl. were marketed during that period, his apportionment of the output among the major fields being as follows:

Appalachian, 11,400,000; Lima-Indiana, 1,800,000; Illinois, 7,900,000; Kansas and Oklahoma, 50,500,000; Northern and Central Texas, 4,200,000; Northwest Louisiana, 6,800,000; Gulf Coast, 11,400,000; Wyoming and Montana, 3,400,000; California, 43,500,000; miscellaneous, 100,000.

This quantity, which includes a little oil actually produced in 1915 but marketed during 1916, is appreciably less than the output during the first half of 1915, though it is greater by about 5,000,000 bbl. than one-half the entire quantity marketed last year. When it is considered that the first half of 1915 includes the period of maximum production of the Cushing pool in Oklahoma and the Crichton pool in northwestern Louisiana the disparity in output between the corresponding periods is not especially significant. The magnitude of this quantity, the fact that is is greater than one-half the total petroleum marketed in the United States in 1915, and the further fact that it reflects the results of general activity throughout all oil-producing areas rather than flush production in restricted areas is, however, significant and leads to no other conclusion than that the final satistics of oil marketed in 1916 are destined to establish a new record.

The outstanding feature of the petroleum industry during the half-year just closed was the high level reached in the prices of crude oil in March and maintained firmly to the end of the period. This level involves prices ranging from 90 to 350 per cent higher than those of a year ago for high-grade Eastern and Mid-Continent grades and reflects less strongly the decreased capacity of Cushing than it does the increased demand for crude oil.

—

K. C. Speedway Nears Completion

KANSAS CITY, Mo., July 3.—The new 1⅛-mile speedway south of Kansas City, being built by the Kansas City Speedway and Exposition Co., will be finished by July 10, and the first event will be staged July 22. Several drivers have signed up for the races, including Ralph De Palma, Hudson; Eddie O'Donnell, Duesenberg; Eddie Rickenbacher, Peugeot; Ralph Mulford, Hudson; Earl Cooper, Burman Special; Jack Gabel, Sunbeam; Art Klein, Miles Special; and there is an entry of H. J. Rahe's Hudson with racing body, Mr. Rahe making the entry from the K. C. Automobile Training School.

The track is a triple radius track, built of the black gumbo that people of this territory known to be pasty and to pack like glue—there will be no holes dug in it by the tires.

—

Uniontown Hill Climb July 20

UNIONTOWN, PA., July 1—The fourth annual Summit Hill Climb under the auspices of the Uniontown Motoring Association will be held July 20 on the mountain course between Hopwood and Summit. There will be three automobile races, consisting of a free-for-all and two races for cars of limited piston displacement. Flying starts of 100 yd. will be given in each event. Entries will close July 17. More than forty cars are already entered, including De Palma. The management expects the entry of Mulford and the Christiaens brothers in their two Sunbeams.

—

More Firms to Protect Soldiers

JACKSON, MICH., July 1—The Briscoe Motor Corp., this city, will place the families of its soldier employees on its payroll during the guardsmen's service to their country in Mexico. Their positions will also be held open for them until they return. It is reported that more than 1 per cent of the employees of the concern are guardsmen in the army.

Several of the automobile concerns in Long Island City will also protect their workmen. The Pierce-Arrow company will hold the men's jobs open until they return and give them full pay all the time they are away.

—

New Miller Tire

AKRON, OHIO, June 29—The Miller Rubber Co., this city, announces its new Millermolded black tread geared-to-the-road tire to be sold at a popular price. The company has been experimenting with this model for over a year.

—

Peugeot Co. to Sell Premier

NEW YORK CITY, July 1—The Premier and the Peugeot cars will be sold together by the Peugeot Import Co., Broadway and Fifty-ninth Street.

—

Oakland Branch in Dallas

DALLAS, TEX., July 1—C. L. Zutavern and others will open a factory branch of the Oakland Motor Co. here to distribute in Texas.

Factory Miscellany

To Make Vulcanizing Machinery—A new factory for the manufacture of vulcanizing machines was opened this week on West Chestnut Street, Canton, Ill. The company is in charge of F. A. Whitten, Charles Palmer and Abe Lewis. The machine produced is a timely invention. By a simple chemical process owners are enabled to repair a break in a tire within 5 minutes and without danger of burning the rubber. The operations of the company will be upon a small scale at the outset, but it is planned to expand as business warrants.

Gillette Tire Plant Progresses—Excellent progress is being made by the Gillette Safety Tire Co., Eau Claire, Wis., on the construction of its new plant and it is expected that the first tires will be coming through before Aug. 15. The main building, the first unit of the proposed group, is 60 x 250 ft. in size. It will be equipped with $30,000 worth of tire and rubber working machinery purchased from the Adamson Machinery Co., Akron, Ohio, and the total investment at this time will exceed $75,000. R. B. Gillette is general manager and J. S. Wilson is secretary. The initial output will be 150 tires daily and between eighty-five and 100 skilled workmen will be employed.

Wis. Factory Items—The Wald Mfg. Co., Eighteenth and Martin Avenue, Sheboygan, manufacturing accessories and parts, will erect an additional machine shop, 80 by 100 ft., one story high, made necessary by the rapid growth of its business.

The Four Wheel Drive Automobile Co., Clintonville, which has more than doubled the size of its works during the last year, is planning to erect a large new gray iron and malleable foundry during the late summer and early fall. A new machine shop, 100 by 200 ft., is now being completed. The company is working on large orders for army commercial vehicles for the American and European governments.

The Kurz & Root Co., Appleton, manufacturing electrical devices, has booked a large order from the United States government for the military electrical generating units which it has built for the last 18 months or more for foreign governments. The unit is designed for military camp service, in connection with the portable machine shops on motor trucks used generally for army service in this and foreign countries. The generator takes the place of the flywheel on a small four-cylinder, four-cycle gasoline engine and produced current for lighting camps as well as for wireless apparatus. The overall length of engine and generator is only 42 in.

The Pan-American Rubber Co., Milwaukee, has been organized with a capital stock of $200,000 to manufacture a patented inner tire, known as the cellular pneumatic inner tire. The concern takes over the business of the Sporub Tire Co., which has been manufacturing inner tires for about 10 months. Factory quarters have been leased in the Kopmeier Building, Third and Prairie Streets, and a large production is planned. At this time about fifty tires are being manufactured daily, but within a short time the number will be increased to 100, and within 60 days to 200. F. J. Ramler, H. C. Clauson and J. Kopmeier appear as incorporators of the new company. F. J. Ramler is president and general manager. He is half owner of the Standard Racine Rubber Co., Milwaukee, and a large stockholder in the Racine Rubber Co., Racine, Wis. He has been engaged in the rubber and tire business for more than 16 years. The cellular pneumatic tire is distinct from so-called tire fillers, in that it is virtually a pneumatic tube without the disadvantages of the ordinary tube and does not require inflation, and may be transferred from one casing to another.

Start Perfex Radiator Plant—Ground has been broken for the new plant of the Perfex Radiator Co., Racine, Wis., which established a factory in leased quarters about 4 years ago for the production of radiators for pleasure and commercial cars, trucks, tractors, etc. The main building will be 85 by 250 ft.

The AUTOMOBILE

VOL. XXXV NEW YORK—THURSDAY, JULY 13, 1916—CHICAGO No. 2

U. S. Places Orders for Trucks Worth $3,500,000

Nine Makes of Vehicles, the Majority Being of 3-Ton Capacity, Included in Order—Two 5-Ton Types Are Ordered

WASHINGTON, D. C., July 8—Nine makes of vehicles are included in the motor truck order placed by the quartermaster general of the army during the past week—an order amounting to almost $3,500,000. Most of these nine makes are of 3-ton capacity, although two makes are of 5-ton capacity. In the purchase of these trucks the War Department has been largely governed by the recommendation of Gen. Frederick Funston, who has learned, through his subordinate officers, of the real needs of the army along motor truck lines, particularly the needs of the present service. Government officials here also are giving some consideration to the type of vehicles purchased to better regulate the models for military use.

To Simplify Purchases

By this means it will be possible, officers say, to eliminate the purchase of too many types, which would require the keeping of manifold parts and greatly add to the repair problem. It is entirely out of the question, experts declare, to adopt a single standard type, owing to the refusal of motor truck manufacturers to depart from their own distinctive designs, which are of commercial value. The order recently given was divided as follows:

Ninety-seven Riker, with bodies, 3-ton capacity; two Riker tank trucks; 8 Riker, with platform bodies, 3-ton capacity; 224 Peerless, with bodies, 3-ton; seventy-three Peerless chassis, 3-ton; two Peerless, platform bodies, 5-ton; twelve Peerless, platform bodies, 3-ton; six Reos, with bodies, ¾-ton; 264 Packards, with bodies, 1½-ton; 132 Packards, 3-ton; 528 Whites, with bodies, 1½-ton; thirty-three Whites, with bodies, 3-ton; ninety-nine Four Wheel Drive chassis, 3-ton; fifty-eight Kelly-Springfield, with bodies, 1½-ton; sixty-six Kelly-Springfield, with bodies, 3½-ton; ninety-nine Kelly-Springfield chassis, 3-ton; thirty-three Velie chassis, 1½-ton; thirty-three Velie chasis, 3-ton; 163 Packard chassis, 1½-ton; thirty-three Packard chassis, 3-ton.

—

France Lowers Truck Duty

PARIS, June 28—*Received in New York July* 12—By the repeal of the import prohibition law, American trucks are now admitted to the French market on the pre-war tariff, which is roughly equivalent to 12 per cent of value. All passenger cars, however, are met by a 70 per cent import duty. This duty applies virtually to all vehicles weighing less than 2½ tons. The adoption of a weight limit instead of an attempt to define a commercial vehicle is a very intelligent move.

—

Congress To Pass Trade-Mark Registration Law

NEW YORK CITY, July 1—Those manufacturers who are interested in export conditions will find it to their advantage by having their trade-marks registered. The United Export Bureau of THE AUTOMOBILE has received information from its agent in Chile, that Congress is about to pass a law in regard to the registration of trade-marks. Up to the present time, this has been a very simple procedure, but the Bureau is informed that in the future it will not be so easy, and above all, the expense for registering the trade-mark will be considerably higher than it is at present.

The United Export Bureau, which is thoroughly conversant with conditions in South America, is taking charge of this trade-mark work, charging a nominal fee to cover its expenses. Those makers wishing to procure the registration certificate may do so by sending the Bureau three copies of the trade-mark, also three photographs of the car which is to be registered.

—

Gaston, Williams & Wigmore Profits $10,000 a Day

NEW YORK CITY, July 7—Gaston, Williams & Wigmore, exporters of trucks and automobiles, this week declared an initial dividend of $1 a share. Earnings thus far this year have increased steadily. For the period from date of organization, April 19, to May 31, profits were $400,000, or $10,000 a day. From Jan. 1 to April 19 they were $1,073,851, or at the annual rate of over $3,500,000, or approximately $10,000 a day.

For the current month, profits will run between $350,000 and $400,000, bringing the total for the first half year up to $1,800,000, or equivalent to $6 a share.

S. A. E. Aeronautic Division to Meet

NEW YORK CITY, July 12—The aeronautic engine division of the S. A. E. standards committee will meet in Washington, Tuesday, July 18. Henry Souther will be chairman of the division and the first meeting will be attended by representatives of the aeroplane industry, government officials and officers of the army and navy.

7992 Cars and Trucks Valued at $8,426,928 Exported in May

Parts, Not Including Engines and Tires, Valued at $789,826—Total for 11 Months Period Is 71,175 Machines Worth $91,594,466—Parts, $20,649,739

WASHINGTON, D. C., July 8.—During May 1717 commercial cars, valued at $4,357,238, and 6275 passenger cars, valued at $4,069,690, and parts, not including engines and tires, worth $789,826, were exported to various countries. During the 11 months ended May the exports were as follows: Commercial cars, 19,849, valued at $53,254,400; passenger cars, 51,326, valued at $38,340,066; parts, not including engines and tires, $20,649,739.

In May a year ago 2426 commercial cars, valued at $6,583,912, together with 4821 passenger cars, valued at $3,971,483, and parts, not including engines and tires, to the value of $789,829, were shipped abroad. For the 11 months' period the exports were 11,006 commercial cars, valued at $30,561,880; 19,462 passenger cars, valued at $16,327,955, and parts, not including engines and tires, to the value of $6,714,001.

Europe Takes Most

As has been the case ever since the European war began, the bulk of our automobile shipments continue to find their way into Europe. A total of 877 cars, valued at $1,764,489, was exported to France in May last, as against 521 cars, valued at $1,106,572, shipped there in May a year ago. During the 11 months' period these shipments increased from 4472 cars, valued at $11,142,414, in 1915 to 7080 cars, valued at $18,054,753, in 1916.

The United Kingdom bought 975 machines, valued at $1,745,415, in May, a considerable falling off as compared to the purchases in May a year ago, which amounted to 4036 cars, valued at $5,895,856. However, this decline was nothing as compared with the big increase in the purchases for the 11 months' period, which in 1916 totaled 17,795 machines, valued at $24,705,017, as against 11,688 cars, valued at $16,736,165, exported in 1915.

Russia, which did not figure in the export tables last year, bought 359 cars, valued at $660,620, in May last, and that country's purchases of American cars during the 11 months' period of this year amounted to 5133 cars, valued at $15,528,974.

Denmark Becomes a Factor

Denmark is another country whose car imports from this country were not separately reported last year, but in May last we shipped there 210 machines, valued at $144,737, while during the 11 months' period the shipments totaled 807 cars, valued at $556,445.

There were no car shipments to Germany during any of the periods under consideration, but Italy took fifty-one cars, valued at $19,376, in May last and 307 cars, valued at $192,107, during the 11 months of this year. Twenty-three cars, valued at $17,004, were exported there in May a year ago. while during the 11 months' period the number was 111 and the value $75,372.

There was a big drop in our exports of cars to "other Europe," the shipments declining from 699 cars, valued at $1,638,709, in May, 1915, to 404 cars, valued at $392,189, in May last, and from 2817 cars, valued at $7,768,101, during the 11 months of last year to 2149 cars, valued at $2,651,331, during the same period of this year.

Shipments to Canada show a big increase from 838 cars, valued at $630,990, in May a year ago to 1779 cars, valued at $1,212,260, in May last and from 3606 cars, valued at $3,796,729, during 1915 to 9212 cars, valued at $6,368,633, in 1916.

Even war-ridden Mexico shows a healthy growth in its imports of automobiles from this country, fifty-eight cars, valued at $53,500, being shipped there in May last, as against three cars, valued at $4,407, exported in May a year ago, while during the 11 months' period the exports increased from sixty-seven cars, valued at $68,067, in 1915 to 396 cars, valued at $381,818, in 1916.

Another section of the world that is showing a fondness for American cars is the West Indies and Bermuda, which took 495 cars, valued at $296,798, in May last and 4355 cars, valued at $2,642,466, during the 11 months of this year. Last year the shipments there amounted to 262 cars, valued at $131,779, during May and 1383 cars, valued at $827,989, during the 11 months.

Under the heading "South American countries," we shipped 165 cars, valued at $88,631, in May a year ago, while during the 11 months of 1915 the exports there amounted to 1071 cars, valued at $583,119. This year the shipments have increased to such an extent that the various countries of South America are listed separately in the export tables and the figures are as follows: Argentina, 578 cars, valued at $279,736, in May and 4075 cars, valued at $1,910,679, during the 11 months of 1916; Brazil, thirty-two cars, valued at $14,944, and 236 cars, valued at $142,191; Chile, sixty-nine cars, valued at $62,736, and 773 cars, valued at $527,291.

Exports of Automobiles, Trucks and Parts for May and 11 Previous Months

	May				11 Months Ending May			
	1915		1916		1915		1916

Hupp Business Gains 47.3 Per Cent

Floorspace Increased 93.9%—Will Produce 18,000 Cars in Next 12 Months

DETROIT, MICH., July 10—With the close of the 1916 selling season, July 1, the Hupp Motor Car Corp. announced an increase in business over the 1915 season of 47.3 per cent. The gain in the Hupp corporation's business was made notable by the fact that for practically 8 months the main Detroit plant has been in the hands of builders. During the past season, the floorspace in the Hupmobile factories has been increased 93.9 per cent, practically doubling the space of 1 year ago.

With the buildings now being completed, the plants will have a capacity more than double that of 1 year ago. The company is installing approximately $500,000 worth of cost-reducing machinery and efficiency equipment in its Detroit and Jackson plants. In preparation for a steadily growing business, the company's investments in enlarging and improving the plants have in the past year aggregated approximately $1,000,000.

The number of factory employees has been increased 74.6 per cent, and an additional increase of nearly 1000 men will be made within the next 90 days, when the final factory additions are completed. A production of 18,000 to 20,000 cars is planned for the next 12 months.

—

General Motors Directorate Includes Chrysler

DETROIT, MICH., July 10—Further revision of the directorate of the General Motors Co. was made at the quarterly meeting, when Walter P. Chrysler, the newly elected general manager of the Buick company, was made a director, following the resignation of S. F. Prior, who is prominent in the Union Metallic Cartridge Co. and the Remington Arms Co.

Thomas Neal, former president of the organization and chairman of the board, is again an officer by his election as vice-president at this meeting. He will share the duties of the vice-presidency with A. G. Bishop, the Flint banker, who was elected a vice-president last fall.

In placing Chrysler on the directorate, another of the General Motors subsidiaries was given representation on the board. Not long ago W. C. Leland, of the Cadillac company, was elected to the board, and with the placing of W. L. Day of the General Motors Truck Co., and F. W. Warner of the Oakland Motor Car Co. also on the directorate, there are four of the subsidiaries directly represented.

These recent director changes followed the resignations of J. J. Storrow, Albert Strauss, Emory W. Clark and S. F. Prior. The revised board as it now stands follows:

Pierre du Pont, chairman; J. H. McClement; C. S. Mott; C. W. Nash, Lammont Belin, A. H. Wiggin, C. S. Sabin, J. A. Haskell, J. J. Roskob, F. W. Warner, W. L. Day, W. C. Leland, W. P. Chrysler, Thomas Neal, W. C. Durant, L. G. Kaufman, and A. G. Bishop.

New Thomas Truck Ready for Market

NEW YORK CITY, July 10—The Thomas Auto Truck Co., Inc., which was organized early this year by C. K. Thomas, formerly vice-president and general manager of the Federal Motor Truck Co. of New York, now has its 2-ton model ready for the market. Eventually there will be three other models rated at ¾-ton, 1-ton and 1½-ton. The 2-ton model is built entirely of standard units the principal specifications including a 4-cylinder, 4⅛ by 5½ Buda motor, selective three-speed gearset, dry-plate clutch in unit with the motor, worm drive, with Timken-David Brown worm and propulsion and torque taken through the spring. Frame is pressed steel with a total overall length of 214 or 232 in. Wood wheels are fitted with 34 by 4 front and 34 by 4 dual or 34 by 6 single rear tires. The steering wheel is at the left with control levers in the center. The standard wheelbase is 150 in. with 168 in. optional and the tread is 58 in. The loading space is 112 in. with 130 in. optional. Regular equipment includes Bosch lighting generator, electric lamps, 6-volt 110 amp.-hr. battery, electric horn, bumper, windshield, front fenders, tools, etc. The company does not manufacture bodies but will furnish conventional designs on orders. Special designs will also be produced.

—

Reo Buys Out National Coil

LANSING, MICH., July 10—The Reo Motor Car Co. has bought out the National Coil Co., which employs about 100 men. The building will be used to extend the manufacturing facilities of the Reo company. Although no figures are given out, it was stated by an official of the Reo Motor Car Co. that it has been decided to build 50 per cent more Reo passenger cars for the season 1917. This will probably mean a total production of from 38,000 to 40,000 cars. A proportionate schedule has been adopted by the Reo Motor Truck Co.

Signal-Commerce Merger

To Be Known as Signal-Commerce Motor Truck Co.—Neal and Parker Heads

DETROIT, MICH., July 8—Merging of the Signal Motor Truck Co., maker of the Signal line of trucks, and the Commerce Motor Car Co., manufacturer of the Commerce trucks, has been effected here. The new organization taking over these two properties is to be known as the Signal-Commerce Motor Truck Co., and it is incorporated under the laws of New York State with a capital stock of 600,000 shares of no par value. The proposition is to be underwritten by fourteen members of the Detroit Stock Exchange, and active in its management will be Thomas Neal, head of the present Signal concern, and W. E. Parker, who is the head of the Commerce company

To Concentrate Production

The capital of the Signal company was increased from $85,000 to $450,000 in January of this year, and by a stock dividend the Commerce company was also raised some time ago to $250,000 capital. It is planned to concentrate the production of a very complete line of trucks, ranging from light delivery types to heavy-duty vehicles, in the new plant of the Signal company, located on Commonwealth Avenue, this city, removing the Commerce manufacturing business from its present location on Mackie and Solvay Avenues.

These two truck manufacturers are strictly Detroit companies, their stock being largely held here. Each makes a range of models of different capacities, and their merger will eliminate a competition between them that was keen. Mr. Neal, at one time president of General Motors Co., later chairman of the board of directors of that organization, and now one of its vice-presidents, is to direct the policies of the Signal-Commerce concern as chairman of the board. Among the directors will be W. E. Parker, who is also connected with the Mexican Crude Rubber Co.; Myron Neal of the Acme White Lead & Color Works, A. H. Buhl, T. J. Bosquette and W. K. Hoagland. There are also several other prominent automobile men interested whose names have not been disclosed.

Stock at $6

To give some idea of the amount of money involved, it is understood that the stock will be offered for subscripton at about $6 per share.

Silence=Continuous Noise

Over 200,000 Sounds Each Minute in a Twelve-Cylinder Car at 20 M.P.H.—Careful Design and Exquisite Workmanship Blend These Into a Pleasant Hum

By A. Ludlow Clayden

FOR the quietness of the modern automobile engineers have hardly received the credit that is properly their due; the immense difficulties with which they have had to contend only appear on a close examination. Some interesting figures can be obtained by calculating the number of opportunities for noise production that exist in a chassis, and the comparative frequency of each gives an opportunity for some "noise analyses" which are instructive.

Just to take a few striking cases, in order to show the idea. Suppose a twelve-cylinder chassis geared between four and five to one on high and running at twenty miles an hour with 34-in. tires. Using round figures we know that the engine fires six times in each crankshaft revolution, that the road wheel revolves 247 times per minute and if the gear is 4 5/11 to 1 the crankshaft revolutions per minute will be just about 1100. To simplify the argument, suppose it is 1000 r.p.m. Then the number of explosions per minute will be 6000 or no less than 100 per second.

400 Valve Shocks per Second

Taking a further step, each valve is opened and closed once to each explosion; so at a rate of 100 explosions per second there are 200 valve-lifting motions performed and 200 valve closings. The crankshaft revolves twice to each explosion and the piston makes four complete strokes, hence the 100 explosions per second represent 400 piston strokes in the different cylinders. Meanwhile the breaker mechanism must operate the contacts in the ignition device 100 times. If a chain front end is used the crankshaft sprocket will have about twenty teeth and will revolve 1000 times in the minute, so there will be 20,000 engagements of chain link with sprocket tooth on the crankshaft pinion; on the camshaft sprocket, and on any other intermediate pinion an equal number of contacts must take place.

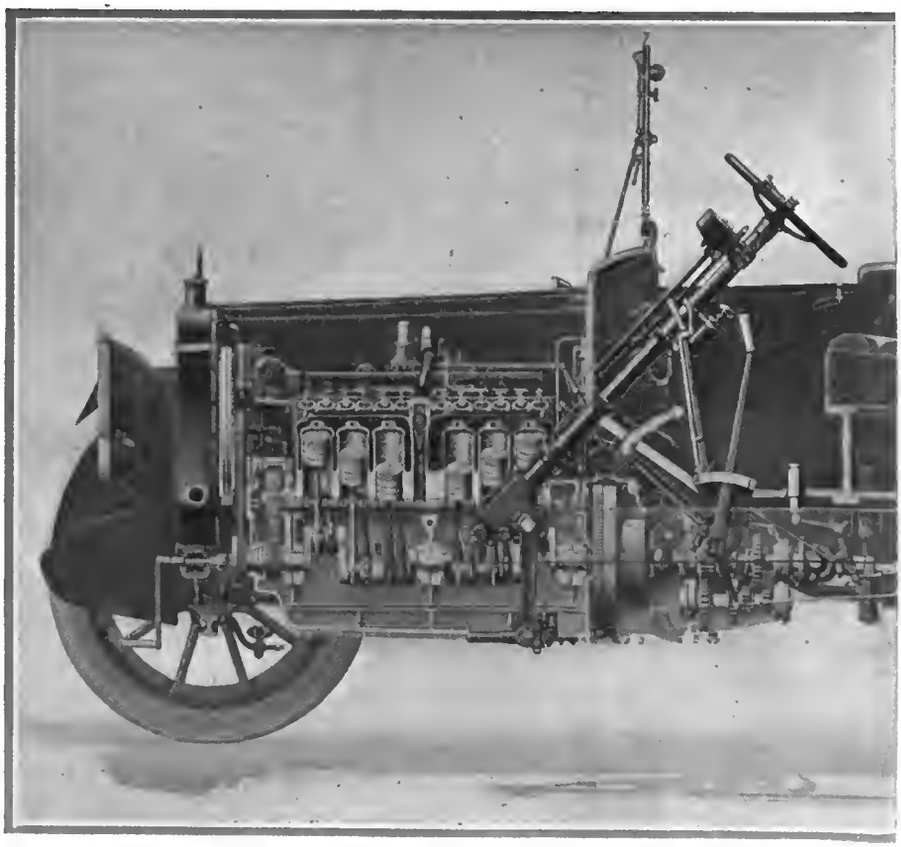
Thus, neglecting any other parts in addition to those mentioned, with a twelve-cylinder car running at 20 m.p.h. there are 2000 things happening every second which have possibilities for noise production; and each minute there will be 120,000.

Engine Makes 150,000 Sounds per Minute

Of course, what happens is that each minute sound blends with the others, so that the resulting sound is practically continuous and capable of being described as a low hum. Even today the predominant sound is almost always that of the escaping exhaust gases and, at certain speeds, the hiss of the air entering the carbureter.

There are many other small joints and connections on the engine which might be included. The generator brushes make and break contact on the commutator bars, the gears in the oil pump can be heard if you run the pump alone in a quiet room, there is probably a bevel geared head for the ignition which runs at a fairly high speed and so on. Altogether it is not too much to say that a twelve-cylinder engine at 20 m.p.h. performs 150,000 operations per minute, each of which could make an audible noise if it were not for the care taken to prevent it. And that engine is comparable with a water tank with 150,000 holes in the bottom, each closed by a cork of clever design and fine workmanship. Any falling off in quality of work means a loose cork and a leaking noise. As for instance a single loose lifter in the valve gear is instantly noticeable as a steady tap, tap, tap.

But, though the engine perhaps contains the greatest possibilities for noise making it is by no means all. In the gearset, in the rear axle, in the universals and in every bearing there is opportunity for sound production. To do a little more rough calculation let us consider the constant mesh gears in the gearset, one of the most troublesome parts from



This section of a twelve-cylinder Packard chassis shows most of the parts men
However, sufficient appear to emphasize the immense amount of engineering
ness of this and other

a noise viewpoint, though one which the average user never thinks about. Suppose there are twenty teeth on the pinion of the constant mesh gear pair, which is about the normal number. Then, since our engine is running at 1000 r.p.m. there will be 20,000 tooth contacts per minute.

Next, take the countershaft. This runs more slowly, say half the speed of the main shaft, and it drives the reverse pinion. Suppose there are sixteen teeth in the reverse pinion which is about as small as it could well be, then there will be 500 times sixteen or 8000 tooth contacts at this point.

Following the gear train through, the next step is the bevel drive of the rear axle. About as small a number of teeth as the pinion is likely to have is thirteen, twelve being the irreducible minimum. Thirteen teeth at 1000 r.p.m. means 13,000 contacts a minute and adding the contacts of teeth in the gearset we get a total of gear tooth contacts per minute of 41,000.

SOUNDS PER MINUTE MADE BY ALL PARTS OF TWELVE-CYLINDER CAR AT 20 M.P.H.

Explosions	6,000
Valves and tappets	24,000
Reversing piston direction	24,000
Breaker mechanism	6,000
Timing gear	60,000
Gearset and bevel drive	41,000
Bearings throughout car	56,000
Total	217,000

Bearings Create Noise

Another fruitful source of an audible, though quite a pleasant sound, is ball bearings. Each bearing contains a number of balls that carry the load when they are on one side of the shaft and have no load on them when on the opposite side. As each ball runs into the half where it is carrying the load it is compressed slightly; in other words it suffers a minute shock. Again, as it runs out of the loaded side into the half of the race where there is no pressure on it, it expands and thus creates another slight shock. Taking a very low estimate, this means that each ball bearing in the chassis, on the average, creates eight or ten tiny vibrations every revolution, roller bearings doing exactly the same thing, of course.

In the gearset there are two bearings at least on the mainshaft which make 1000 r.p.m. or a total of 16,000 shocks per minute. On the countershaft there will be another pair of bearings which run at half speed and so cause half the number of shocks or 8000, giving a total of 24,000 per minute for the gearset. In the rear axle there will be two races making 1000 a minute on the bevel pinion shaft, giving another 16,000 and the two bearings supporting the differential together with the two at the outer ends of the axle driveshafts will account for another 8000 shocks. This is figuring on a semi-floating axle, if it is floating another 4000 is to be added.

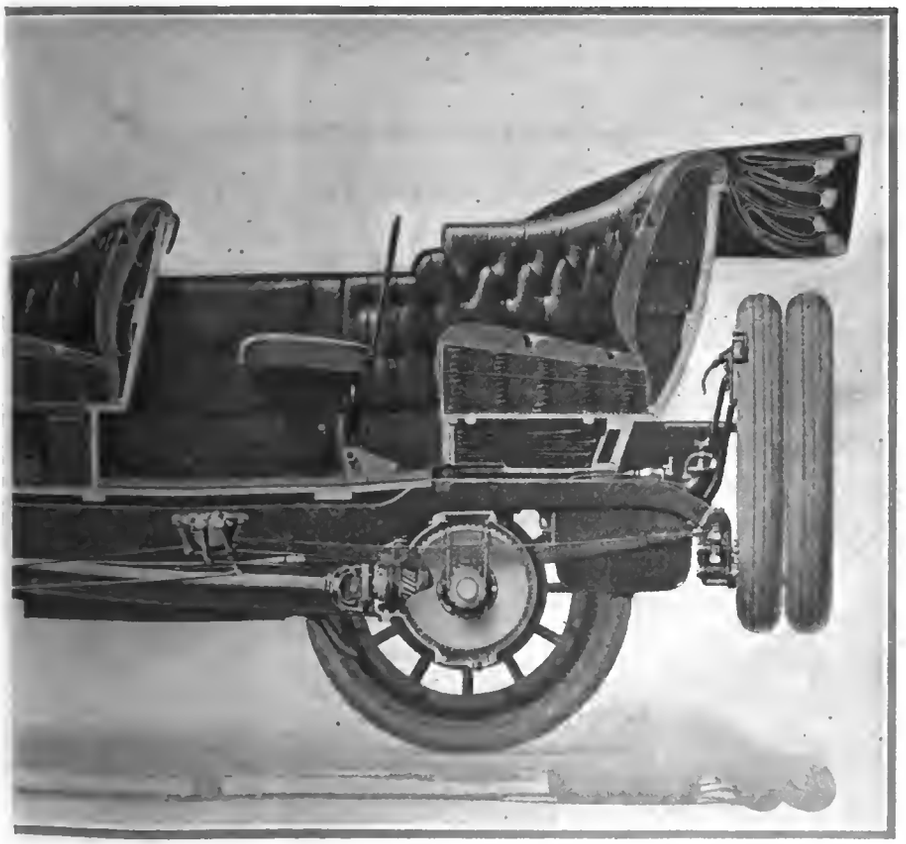
In the front wheels there will be at least four races of ball or roller bearings and these will cause another 8000 shocks between them. This completes the consideration of the principal parts of the chassis, with the exception of the universal joints, but as the stress on these is steady and does not vary in direction there is no reason why they should produce any sound, however small.

In the foregoing many other possible sources of sound have been neglected. For example there are probably gears to drive the speedometer, there may be ball bearings in the generator, there are ball thrust bearings which can make a sound if they are not perfect in manufacture and there are the engine auxiliaries already mentioned. One other thing which ought to be considered is the cooling fan which makes a hum by the action of its blades and also has to stand for at least 24,000 vibrations in the ball bearings which carry it, although, of course, like all other bearing variations, the amount of each is practically molecular in smallness.

Adding up all the sources of sound itemized we get the surprising total of 217,000 things which happen every minute, each of which taken individually is able to cause a sound. In an automobile running at 20 m.p.h. the hum which one hears is composed of *nearly a quarter of a million individual sounds.*

An experiment which may serve to illustrate what happens is to hold down the loud pedal of a piano and then to strike every note simultaneously. After the first crash has died away all the strings will be vibrating and a low sound will be heard that is a blend of all the chords and dischords of the keyboard. With the standard piano this is only a blend of eighty-four notes as compared with the 217,000 of the car.

Another rather interesting thought is that each of the 217,000 sounds taken alone, if they could be isolated, would produce a recognizable note. The smallest number of vibrations per second that is distinguishable as a steady note is sixteen, and this is said to be the pitch of the note made by a big bee. The middle C of a piano should give 512 vibrations per second, and the high C 1024 vibrations, while the highest pitch which any human ear can catch as a sound at all is 40,000 vibrations per second. In an automobile a definite note is to be avoided, and



tioned in the anaylsis of sound production. It does not show quite all of them. knowledge and of manufacturing skill which makes possible the extreme quiet high-grade chassis.

the reason that gears are such a particularly troublesome part to quiet is because they readily produce a note which is within the scale to which the ear is accustomed. For instance, as the middle C has 512 vibrations per second, this corresponds to a gear with twenty teeth running at 1536 r.p.m. Accuracy in workmanship can minimize the shock which occurs as each pair of teeth engage, and the use of large pitch, so as to reduce the number of vibrations per second by cutting down the number of teeth lowers the pitch of the note. A lower pitch not only is less irritating to the ear, but it blends more readily with the other sounds, hence the reason why coarse pitch gears often operate with such desirable quietness.

In the days when motoring was new S. F. Edge, of Napier fame, once said that there is in this world no such thing as silence, there is only continuity of noise. It is a succinct phrase and its truth is perhaps enhanced by the figures itemized above.

Determining Center of Gravity and Moment of Inertia

By Harry B. Wrigley

THE center of gravity and moment of inertia are properties well-known for common sections of beams, shafts, etc., but for other sections, as automobile axles, machine frames, rails, crane-hooks, etc., where the outline is such that the integration in the expressions for center of gravity and moment of inertia is difficult, the following graphic method will be found convenient.

Let it be required to locate an axis passing through the center of gravity of the axle shown in the figure.

Draw axes 1-1 and 2-2 at a convenient distance h apart, parallel to the required axis.

Draw any line as 3-3 parallel to 2-2 and project the points b-b on 2-2; from O and through the intersections on 2-2 draw straight lines intersecting 3-3 at b'-b'; continue this process by determining other points b'-b' and connect them to produce a transformed section.

The statical moment, M, of a plane surface with respect to an axis in the plane is equal to the sum of the products of the elementary areas and their distance from the axis considered, or, it is the product of the area of the plane surface and the distance of its center of gravity from the axis.

Measure the area of the original section and let A denote this area; also let d be the distance from 1-1 to the gravity axis; then by definition $M = Ad$. Measure the area of the transformed section $b' \ldots b'$ and let A_1 denote this area; then M, for the original section $= hA_1$, therefore $d = \frac{hA_1}{A}$, which will now be proved.

Let e denote the distance from axis O-Y to b;
e' the distance from axis O-Y to b';
ew an elementary area;
S the distance of ew from axis 1-1.

It will be noticed that $\frac{e}{h} = \frac{e'}{S}$,

hence $e = \frac{e'h}{S}$

By definition $M = ew.S \ldots\ldots + ew.S$
$= h(e'w \ldots\ldots + e'w)$
$= hA_1$

but $M = Ad$, therefore $d = \frac{hA_1}{A}$

To determine the moment of inertia of the section with respect to its gravity axis.

Project the points b'-b' on 2-2; from O and through the intersections on 2-2 draw straight lines intersecting 3-3 at b''-b'' and through these points construct a second transformed section.

The moment of inertia I of a plane surface with respect to any axis as 1-1 is the sum of the products obtained by multiplying the area of each element of the surface by the square of its distance from the axis.

The moment of inertia I of a plane surface with respect to any axis as 1-1 is equal to the moment of inertia I_g with respect to a parallel axis passing through the center of gravity of the surface plus the product of the area of the surface by the square of the distance between the axes; then $I = I_g + Ad^2$.

Measure the area of the transformed section $b'' \ldots b''$ and let A_2 denote this area, then for the original section $I = h^2A_2$, therefore $I_g = h^2A_2 - Ad^2$, the required moment of inertia.

Let e'' denote the distance from axis O-Y to b''.

Then $\frac{e'}{h} = \frac{e''}{S}$ and $e' = \frac{he''}{S}$; but $e' = \frac{es}{h}$ as before, hence

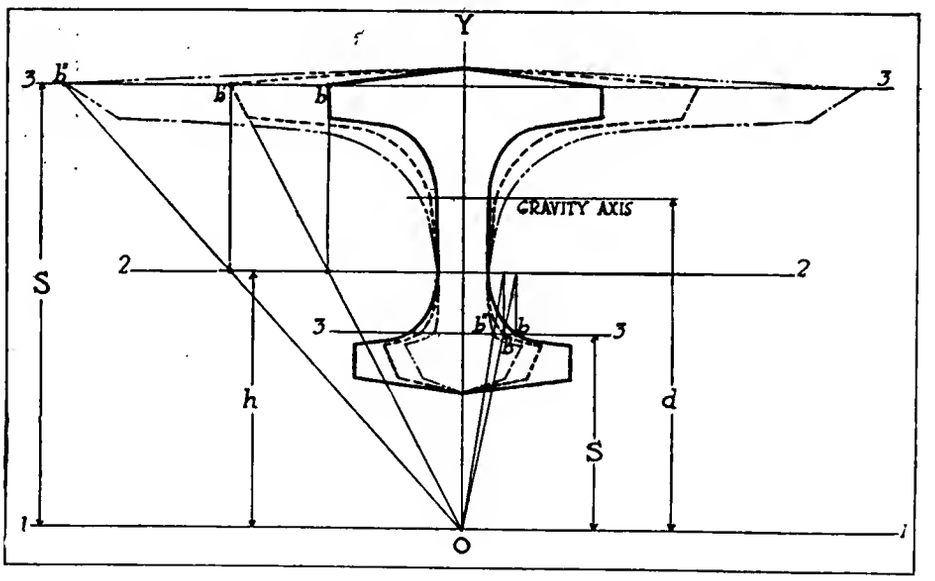
$S^2 = \frac{h^2e''}{e}$

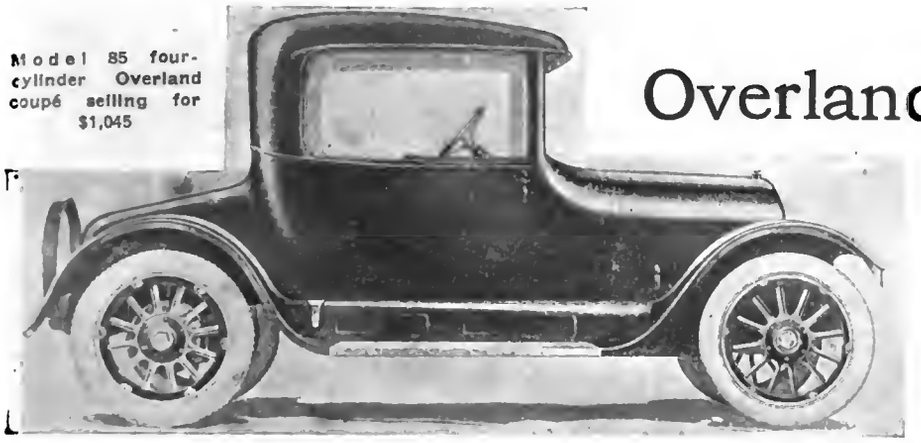
By definition $I = ew.S^2 \ldots\ldots + ew.S^2$
$= h^2(e''w \ldots\ldots + e''w)$
$= h^2A_2$

Armored Cars for U. S. Warships

Armored automobiles cradeled on the decks of warships, in seagoing rafts, for the use of detachments of the United States marine corps in short operations, may soon be added to the regular equipment of naval vessels.

Experiments at the Boston navy yard have demonstrated that these cars can be stowed aboard by the means of electric cranes on war vessels in a few minutes.





Model 85 four-cylinder Overland coupé selling for $1,045

Overland Fits Battery Ignition

Small Four Little Changed—Model 83 Discontinued—New Model 85 as Four and Six

IN the 1917 models of Overland cars made by Willys-Overland company, Toledo, Ohio, it is easy to see that many of the features of the little four which appeared last November have proved so good that they are now seen on the whole range of models. For example, the pressed steel rear axle case used for the small car is now found on the larger one, and the same is true of the cantilever springs. Sizes, of course are different, but the designs are almost identical.

Present models are series 75-B, the little four, and series 85, either four or six. Model 83 is discontinued altogether. The small car sells for $635 as a touring car and $620 as a roadster, while the model 85 touring car is $795 as a four and $925 as a six.

Will Use Battery Ignition

For the first time the Overland company will abandon magneto ignition for all its models. The new ignition incorporates a thermostatic throw-off arrangement, by means of which it is impossible to drain the battery through neglect to pull out the switch button. The current passing through the switch causes the temperature to rise in the thermostat, allowing it to bend and close an electric circuit, permitting the current to flow through a coil somewhat like a buzzer. This buzzer arrangement hammers on the switch button until it is thrown out, thus breaking the ignition circuit and preventing exhaustion of the battery.

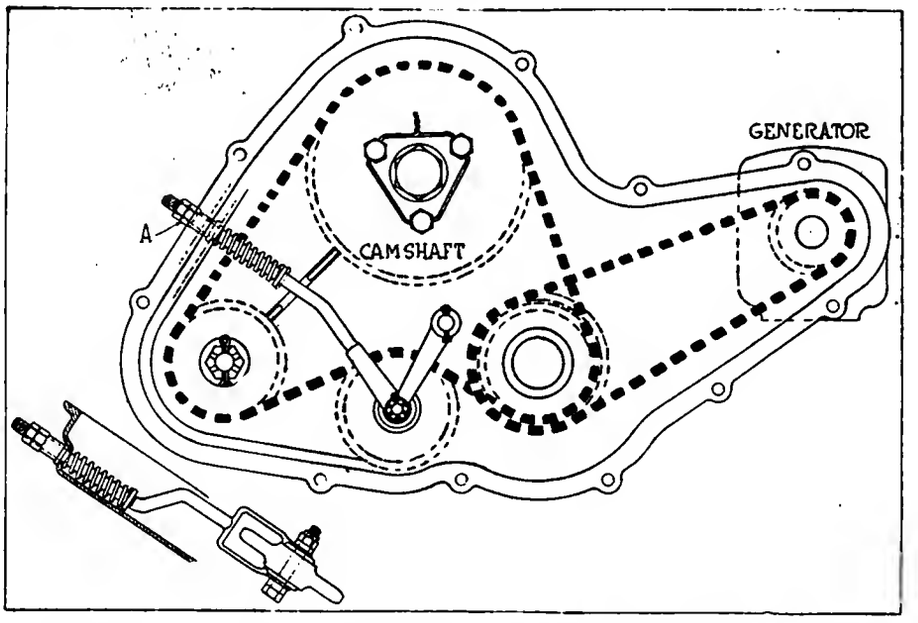
Among other changes it will be observed that the gasoline tank has been moved to the rear and a new form of rigid tire support has been incorporated. On the six-cylinder car, spiral bevel gears are used for the rear axle, while on the four-cylinder model the rear axle gears have straight teeth. The use of a leather universal joint is another innovation.

Probably the most outstanding feature of the model 85 Overland is the particular attention which has been paid to riding comfort. In relation to price both cars are quite long, the wheelbase of the four being 112 in. and of the six, 116 in. Both have large, comfortable bodies, with ample seating room for five persons. In addition to the improvements mentioned above, the seats in these new models have been built lower and deeper with a slight backward tilt to allow the passengers to relax slightly in the seats, and the seat cushions are built on deep coil springs which bear their share in the easy riding qualities of the car.

In the four-cylinder car, the power plant is a development of the four-cylinder engine which has now been used on over 300,000 Overland cars. It is of block design with a bore of 3¼ in. and a stroke of 4½ in. The manufacturers claim that it will readily develop 40 hp. The cylinders are iron castings and the pistons are also of cast iron. The piston length is 4 in., and the number of rings is two on this model. Connecting-rods are 8½ in. long and are of drop forged I-beam section. The crankshaft is carried on five main bearings and has a diameter of 1½ in. The engine is cooled on the thermo-syphon system, and one of the features of the engine is the large waterjacket space surrounding each cylinder.

The capacity of the radiator is increased by fitting of an auxiliary tank at the top, and the radiating surface is also augmented by corrugations in the thin vertical tubes of which it is com-

New universal used on model 85 Overland



In the Overland camshaft drive by silent chain the idler design has been changed. Formerly the idler was pulled against the chain by a spring, now the nut and lock nut A outside the timing case give a positive adjustment, the spring inside having only a limited cushioning effect

posed. A shell of pressed steel acts as a protective housing for the radiator tubes and this is made from a single piece of steel having no joints in the metal. The shell is supported in swivel seats which relieves the radiator from any stresses which would be due to racking of the frame.

Splash-feed lubrication is used on the constant-level system in which the oil is continuously drained. A small gear oil pump located within the crankcase in a well at the rear end provides a steady flow of lubricant and also sends the oil through a revolving sight feed on the dash. The oil passes through the sight feed and returns to a lead which runs the length of the crankcase, supplying each of the troughs with a quantity of lubricant and keeping them constantly full. The overflow from the trough escapes back to the well in the crankcase, after which it is strained before again being circulated. The sight-feed indicator on the cowl dash clearly shows the flow of oil, for the oil in passing through it revolves a small fan-bladed wheel close to the glass face. There is also a float gage on the crankcase which indicates the amount of oil in the reservoir and the breather tube is widened at the top so as to also act as a filler opening.

New top fastening on the model 85. This simple and positive device greatly simplifies top manipulation

Six and Four Alike

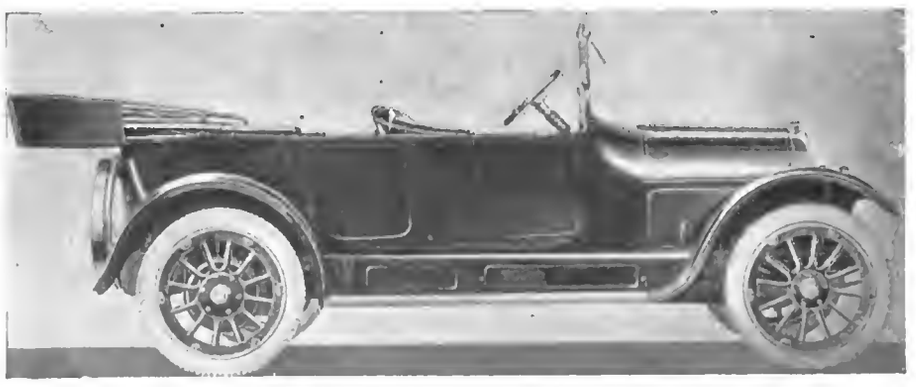
Other than in the power plant, the six-cylinder car is exactly the same as the four, except that the longer engine necessitates a longer hood and consequently a slightly longer wheelbase, the exact difference being 4 in. All this difference in length is made up at the front end of the car, necessitating, of course, a longer frame on the six than on the four. The six-cylinder engine is also a block design and is characterized by an extremely clean exterior. It has a bore of 3¼ in. and a stroke of 3½ in. It develops from 35 to 40 hp., according to the manufacturer's figures. The cylinder heads are removable and are cast in one piece, this construction giving great accessibility and also permitting accuracy in manufacture, particularly as regards the ability to machine all cylinders to a uniform size, thus having the effect of giving uniform compression in all cylinders. Throughout the engine is of conventional L-head design, with both the intake and exhaust manifolds on the right side, together with all the auxiliary apparatus, such as the water pump, ignition distributer, generator, starting motor, etc. The only parts mounted on the left side are the carbureter, the oil filler and the oil level gage.

The clutch is a leather-faced cone with three tension springs spaced evenly around, close to the rim. In releasing the clutch, six small spring studs press outward against the leather, raising it in spots, and when the clutch is engaged these raised spots touch first, providing a gradually increasing contract until the springs are fully depressed and the whole surface engaged. There is also a small fiber-faced clutch brake which stops the spinning clutch member and allows of easy gear shifting.

One Leather Universal

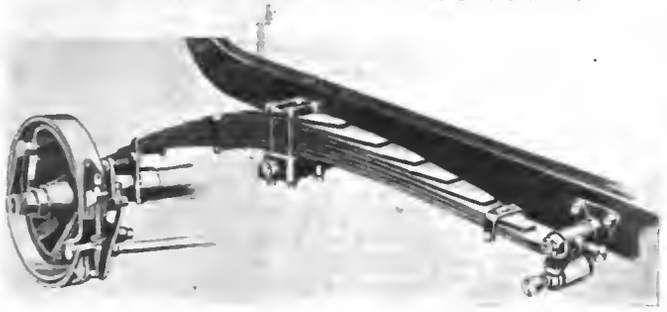
There is only one universal, this being the new leather design, since the gearbox is mounted in a unit with the rear axle. This gearbox provides three forward speeds and is made up of double heat-treated nickel steel gears of stub-tooth type. The shafts are carried on both roller and annular ball bearings. The rear axle is a floating type and as stated, on the four has straight teeth, while on the six it has spiral bevel teeth. There are four differential gears and the shafts are removable. The differential is carried on adjustable taper roller bearings, while the wheels are on annular ball bearings.

Two sets of brakes are used, the service set being contracting type, 13⅜ by 2¼ in. The emergency are expanding 13 by 2¼ in. Both sets



Overland 85-4 five-passenger touring car, which sells for $795

The cantilever springs used on model 75-B Overland are slung under the axle and the side members of the frame



On the 85 Overland, the rear cantilevers are mounted over the axle and at the sides of the frame members

operate on the rear wheel drums and are lined with asbestos fabric on woven brass wire core. The springs are semi-elliptic front, 36 by 1¾ in. and cantilever rear, 48 by 2¼ in. The wheels are wood, and the tires, 32 by 4 in., fitted with straight side tires and non-skids in the rear. On the touring sedan, mounted on the 85 chassis, the tires are 33 by 4½ in.; demountable rims are used throughout.

Bodies Last Word in Modernity

In the body work, the up-to-date conception of streamline design has been carried out through the entire line. The touring body is built with one-piece cowl and high-backed seat. The doors are hinged in front so that in case they are accidentally left open and strike an object they will be slammed shut instead of broken off. The doors are U-shaped, fitted with disappearing hinges and provided with large pockets, while the tool compartment is located under the front seat. Fenders are of heavy shaped steel and are crowned. The finish is Brewster green with ivory striping and the fittings are nickel and polished aluminum, while the fenders and other trimmings are black enamel.

Equipment Is Complete

The price of $925 for the six-cylinder and $795 for the four-cylinder touring car includes full equipment with Auto-Lite two-unit, 6-volt electric lighting and starting system; a complete set of lamps, dimmers and ammeter. There is also a speedometer and an oil pressure gage, complete tool equipment and an extra demountable rim. The top is a one-man mohair and the curtains are fastened from inside. The windshield is built in and incorporates both the rain vision and ventilating features. On this same chassis there is a touring sedan at $1,195 in four-cylinder, and $1,325 as a six, and a touring coupé at $1,045 and $1,175.

More Power in Small Four

The model 75-B is a new series which has taken the place of the previous small four-cylinder car. It is characterized particularly by a more powerful engine which is claimed to develop 31½ hp. at 1950 r.p.m., and to have a speed range of from 2½ to 53 m.p.h. on high. Another feature of the car is that it is equipped with 4-in. tires. It has cantilever suspension, two-unit, 6-volt lighting and starting and complete equipment. The body is new and is fitted with a one-piece cowl which slopes back in a graceful curve, preserving the characteristic Overland outlines.

Intake Manifold Cored in Casting

All four cylinders are cast in a block, having a bore of 3⅜ in. and a stroke of 5 in. and the combination of block casting with thermo-syphon cooling gives a very clean motor. The only auxiliary drive is that of the ignition distributer which is now used in place of a magneto and is mounted on the right side of the engine, back of the timing gear case. The valve mechanism drive is by silent chain and this drive also takes care of the distributer. The intake manifold is cored in the cylinder casting and delivers a warm mixture to the cylinders which is one of the factors in increasing the economy of the car.

Constant Level Splash Oiling

Lubrication is by constant level splash, the oil being circulated by a small pump which constantly maintains a supply of lubricant in the troughs beneath each cylinder. The clutch is the Overland type similar to that described for the model 85, having the three engaging springs with the auxiliary springs beneath the surface of the leather cone facing. The gearset is on the rear axle and is similar in design to that of the larger model, with three speeds and with nickel steel gears carried on shafts that are mounted on roller and annular ball bearings. The axle is floating and an unusual feature for such a low-priced car is that the differential is made up of four bevel gears. The axle shafts are removable and the bearing equipment is annular ball.

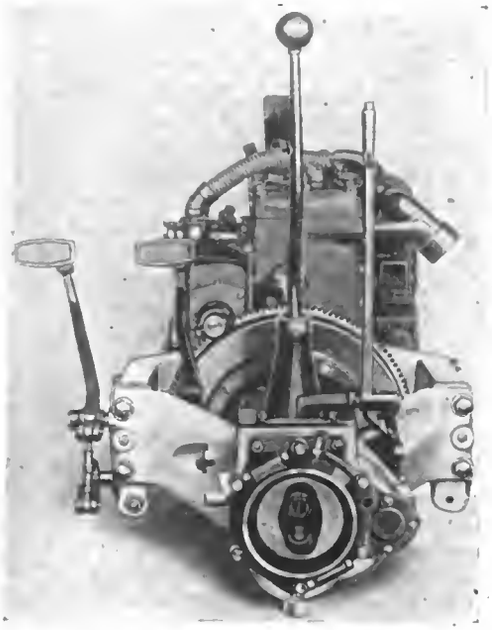
Fabrikoid Upholstery a Feature

Two sets of brakes are used, the surface being contracting 12⅜ by 1¾ in. and emergency 12 by 1¾ in. The springs are semi-elliptic, 36 by 1¾ in. with cantilever rear, 42 by 2 in. The tires are 31 by 4 in. mounted on artillery type twelvespoke wheels with demountable clincher rims. The bodies are streamline provided with Fabrikoid upholstery, front-hinged U-doors with large pockets and tool compartment beneath the rear seat. Heavy sheet steel crown fenders are fitted, and the finish is black and nickel and polished aluminum trimmings. The equipment is complete, including Auto-Lite starting and lighting, full set of lamps, ammeter, one-man Mohair top, inside fastening curtain, electric horn, combination tail light and license bracket, hinged robe rail, foot rest, tire carrier and extra demountable rim. There is also a full set of tools.

Instrument board of the 75-B Overland is compact and neat

Paige Makes Few Changes

Continues Models Seen at National Shows —Bodywork Has Been Improved, Giving More Room and Better Finish for 1917



Rear view of unit power plant used on Paige 6-38, showing control levers

AT the New York show last January a new model Paige known as the Fleetwood 6-38 appeared, this being an addition to the Fairfield model 6-46, which is a larger car. The 6-38 will be continued without any changes, but there have been a few alterations in the Fairfield model, mainly in connection with the body. The Paige-Detroit Motor Car Co., Detroit, Mich., has, like so many other manufacturers, found it necessary to raise its prices slightly, the smaller car now costing $1,090 as against $1,050 and the larger $1,375 as compared with $1,295. These prices are for five-passenger or roadster on the small chassis and seven-passenger or roadster on the larger six.

The changes in the 6-46 are not radical, but incorporate a few body alterations of importance and one mechanical difference. The body changes are a sloping windshield, instead of the vertical type formerly employed; a new form of upholstering in which the leather is arranged in piping, giving a long, tufted effect. Better springs are also used in the upholstery and these tend to make the car easier riding. Leather door flaps have been added and, in addition, there have been some improvements in the equipment in the form of a Boyce Moto-Meter, a vertical tire carrier in place of the slanting one on the previous car and a mahogany instrument board. A feature is made of the oversize tire equipment on this car and the color has been changed to Brewster green with ivory white wheels and black bonnet.

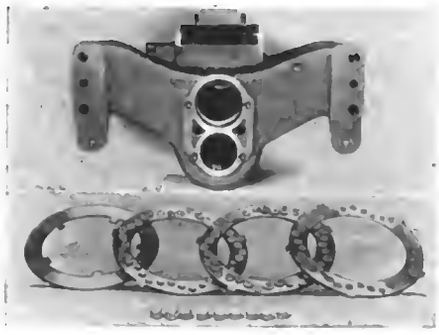
Has Gearbox Tire Pump

The only mechanical change is the addition of a single cylinder tire pump which is mounted on the gearbox and driven from the reverse idler pinion. This pump is a Stewart design and is arranged so that it is easily thrown into mesh by a lever projecting through the floorboard, and is of sufficient size to pump one of the 35 by 4½-in. tires the car uses in less than 5 min.

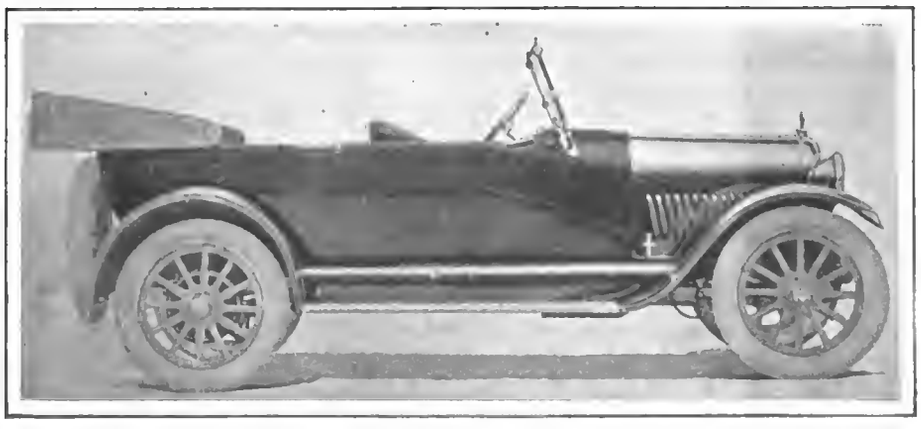
The Paige 6-46 chassis carries the Fairfield touring body and the Meadowbrook roadster. It is the larger of the two sixes and has a 124-in. wheelbase with a standard tread of 56 in. The engine is a block-cast 3½ by 5¼-in. unit power plant, having the clutch and gearset integral. The cylinder casting is of gray iron, while the crankcase proper is aluminum, the lower half of the crankcase which incorporates the oil pan being pressed steel. Valves are on the right and are composite, having nickel steel heads welded to 0.20-0.30 carbon steel stems. The entire valve mechanism is inclosed by aluminum cover plates, and the working parts are submerged in oil. With the aluminum covers and the block casting, a very simple exterior appearance is given the engine while, at the same time, the plates are removable and give easy access to the valve adjustments.

The crankshaft is a drop forging of alloy steel and every shaft is balanced individually for both running and static balance. The shaft diameter is 2¼ in. and three bearings are used for its support. The camshaft is also a carbon steel drop forging, having the cams integral with the wearing surfaces hardened and ground. The camshaft is carried in three die-cast bearings. In both the crankshaft and camshaft the bearing diameters are liberal, as are also the lengths. The crankshaft main bearings have the following dimensions: front, 2 3/16 in. diameter, 3 5/32 in. length; center, 2 7/32 in. by 2⅛ in.; rear, 2¼ in. by 3 9/32 in. The camshaft bearings measure: front, 2 17/64 in. diameter by 1 11/16 in. length; center, 2¼ in. by 1⅛ in., and rear, 2 7/32 in. by 1¾ in.

Drop forged, heat treated, I-beam connecting-rods are used of 0.35 carbon steel. The wristpin bearing has a diameter of 1 3/32 in. and a length of 1½ in., and the lower connecting-rod bearing has a 2 in. diameter and a 2 3/16 in. length. These rods, together with the pistons and the entire



Above—Massive aluminum gearbox. Below—Clutch disks in various stages



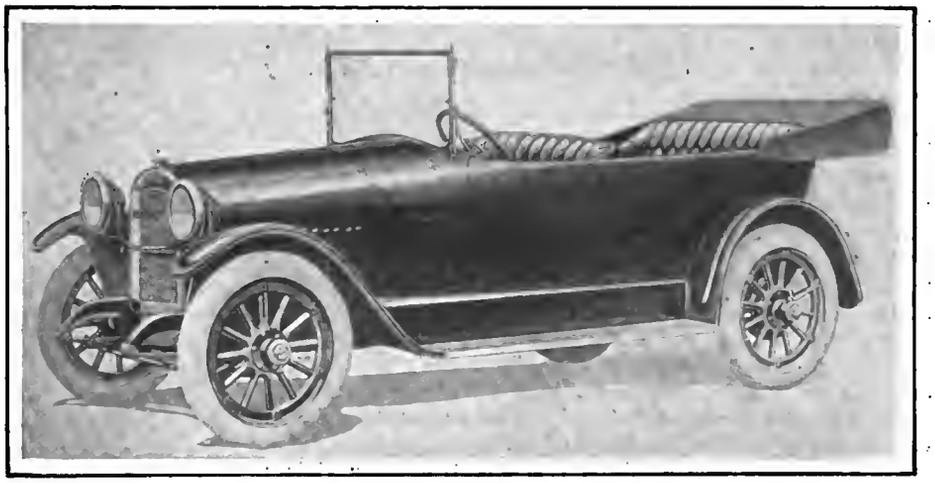
The Paige Fairfield model 6-46 seven-passenger touring car, which now sells for $1,375

reciprocating assembly, are balanced in sets, so that each complete assembly for a given engine must have a proper balance within very narrow limits.

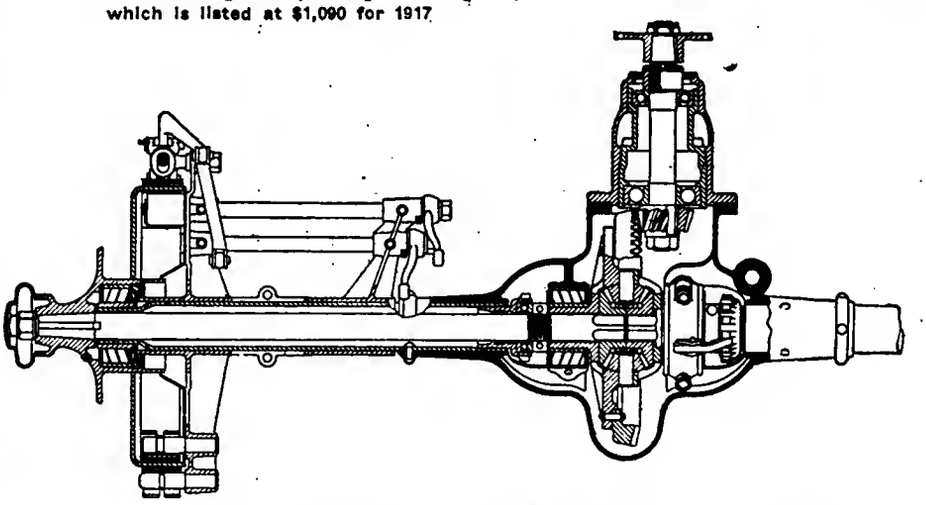
High Efficiency Sought

In carrying out the valve design particular attention has been paid to securing good volumetric efficiency at high speed. The diameter of the valve head is 1 11/16 in. and the opening of the port in the clear is 1 17/32 in. The valve lift is 5/16 in. The design of the valve is conventional with the 45 deg. seat, and the stem diameter is ⅜ in. The valve timing is also conventional, having the inlet opening at 10 deg. after top dead center with inlet closing at 28 deg. after bottom dead center. The exhaust valve opens 40 deg. before bottom center and closes 2½ deg. after top center. This leaves a 7½ deg. negative lap, during which time the piston descends a short distance on the suction stroke, allowing a vacuum to be created sufficient to overcome the inertia of the intake gases.

Lubrication is by a combined pressure and splash system. Oil is carried in the lower half of the crankcase, which has a capacity of 8 qt. A plunger pump operated from the camshaft forces the oil directly to each of the main bearings and to the helical timing gears. This gives four leads from the oil pumps as there are three main bearings and there is an independent lead to timing gears. Oil is forced through these leads in much greater quantity than is consumed by the main bearings, and the resulting overflow is allowed to pass into a series of splash troughs which are arranged one below each crank throw. The dip of the revolving cranks splashes enough oil to lubricate the remaining bearing surfaces, including pistons, cylinders, camshaft and cams.



Fleetwood model Paige five-passenger touring car, which is listed at $1,090 for 1917



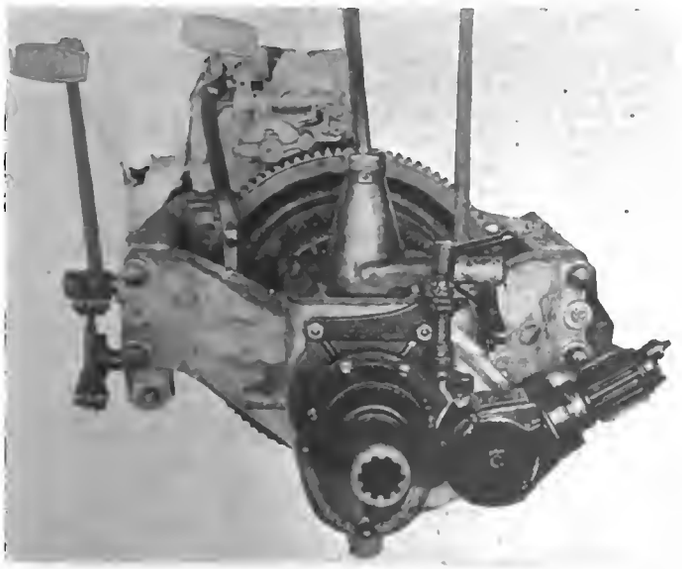
Section through the rear axle used on the Paige Fairfield six model for 1917

Cooling is by centrifugal pump which forces water to a zig-zag cellular radiator having a capacity of 7½ gal. Cooling is assisted by a ball-bearing four-bladed aeroplane type fan, which is hung from a casting directly on the front of the engine.

Gravity Gasoline Feed

The gasoline feed system is by gravity, the tank being located beneath the cowl and having a capacity of 14.7 gal. The carbureter is a Rayfield, supplied with both hot water jacket and hot air intake pipe. The exhaust manifold is located on the opposite side of the cylinder box from the carbureter and hence, in order to get the supply of hot air to the carbureter, it is necessary to carry it across the engine. This is done by fitting the hot air stove around the exhaust pipe and then carrying the hot air lead through the cylinder block between the third and fourth cylinders. Connection is made to the carbureter by a flexible tube on the opposite end of the passage. The hot air is thus provided directly from the exhaust manifold and is maintained at a high temperature by having it pass through the cylinder block where it comes in contact with the hot walls of the cylinder and also with the waterjacketing.

Electrically, the car is Gray & Davis as far as starting and lighting are concerned, while ignition is taken care of by the Remy high-tension distributer and Willard 6-volt storage battery. The starting and lighting system is a two-unit design with a series wound motor, meshing with the flywheel ring gear by means of a Bendix drive and a shunt wound generator on the right side of the engine, driven directly off



Mounting of the new power tire pump on the gearbox of the Paige Fairfield model for 1917

the water pump shaft through a flexible coupling. The automatic cut-out, which is a magnetic design, is mounted directly on the top of the generator, where it is easily reached.

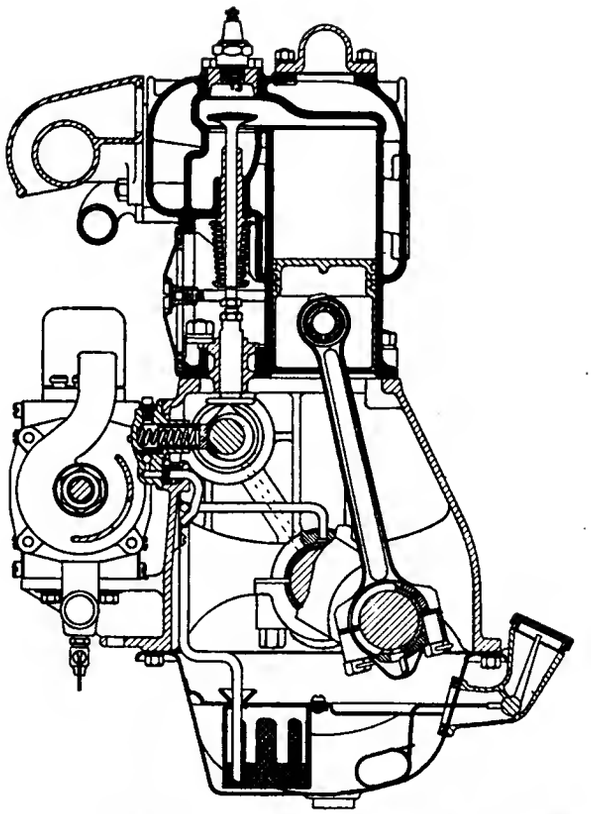
Clutch Runs in Oil

Power is transmitted through a multiple disk clutch, fitted with cork inserts, the entire clutch being inclosed within the flywheel and running in oil. The drive is carried back through a three-speed gearbox having an aluminum case which is a unit with the crankcase. The gears are of chrome nickel steel, hardened and ground, and the shafts are carried on both annular and Hyatt roller bearings. The main shaft is mounted on two annular ball bearings, while the countershaft is carried on two Hyatt high duty roller bearings. Lubrication for the gearbox is taken care of by transmission oil and the capacity of the box is 2 qt.

From the gearbox the drive is taken through a Spicer universal joint to the rear axle. This is a floating type having both the axle shafts and differential on Hyatt high duty roller bearings; the torque on this model is taken through a torque arm. The rear axle is geared 4.357 to 1, having a fourteen-tooth pinion and a sixty-one-tooth ring gear. This gives a reduction on low speed of 14.157 to 1, on second of 7.189 to 1, and reverse, 18.876 to 1. Two sets of brakes are used, working on 14-in. steel drums. The face width of the brake tooth is 2 in., one set of brakes being expanding and the other set contracting.

The front axle is a one-piece drop forged I-beam, heat-treated and provided with ball bearing spindles. The frame is of high carbon steel, channel section, having a 4-in. web and a 3-in. flange: the thickness of the material is 5/32 in., and it is narrowed in front to permit of a small turning radius, while at the rear there is a kick-up over the axle to reduce the height of the body. Springs are semi-elliptic front with cantilever rear, the fronts being 36 in. long and 2 in. wide, and the rears 48 in. in length and 2½ in. wide. The tires are Goodyear or Firestone, with non-skid tread on the rear. The steering gear is the Jacox irreversible screw and split sleeve type, adjustable for wear in any direction, with a steering wheel 18 in. in diameter in one piece, and made with a corrugated inner edge. The horn button is in the center of the steering wheel.

In bodywork, as noted, the cars have been very much improved, especially as regards fitting. The touring bodies are particularly roomy and easily carry a seven-passenger load. Some of the body measurements which are pertinent are as follows: front compartment from back of seat to toe board, 40 in.; height of cushion from floor, 13 in.; depth of seat cushion, 17 in.; width of seat, 47 in. and length of front compartment, 42 in.



Transverse section through the engine of the new Paige

The rear compartment measures from the back of the seat to the back of the auxiliary seat, 26 in., height of cushion from floor, 16 in.; depth of seat cushion, 19 in.; width of seat cushions, 48 in.

A Deferred Payment Difficulty

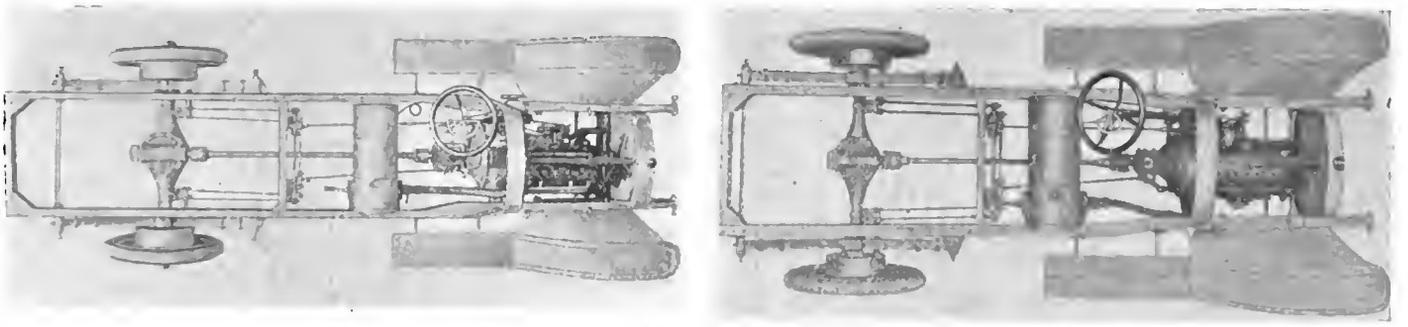
THAT an automobile manufacturer may retain title in an automobile even though he has received the whole amount under a sale contract, is the decision in a recent New York case.

The manufacturer had an agreement in writing with its agent in the city of Elmira, which contract was styled a "Limited Agency Contract." Under it the agent agreed not to sell automobiles for less than their list price; that he would advance in cash the sum of 85 per cent of the full advertised list price of each automobile at the time of its consignment to him; that his commission should be 15 per cent of the full advertised list price, to be paid by the company after payment of the full purchase price by the purchaser, and many other stipulations were contained in the contract.

In 1913 the agent sold a car and took from the buyer what was styled a "buyer's order and agreement." This was approved by the company and it was agreed that the car was to be paid for in monthly payments of $50 each. Thereafter the car was levied upon by a sheriff, who sold it under an execution issued on a judgment obtained against the purchaser. As the agent had forbade the sale of the car, he sued the sheriff to recover the sum of $195.70 which he claimed as his interest in the automobile.

The court held that the motor company, even after it had been paid the 85 per cent of the list price of the car, could have taken the car from its agent, as it held the title to it until the agent and the person to whom he sold it had fully performed their agreements.

It was further held that the cars were not sold to the agent at 85 per cent of the list price under the agreement, as the company restricted the sale of its cars at less than the list price and that such a contract was not against public policy under the decision of Ford Motor Co. vs. International Automobile League, 209 Federal 235, as that case did not hold that the company could not enforce its contract with its agents and fix a price at which its cars should be sold by them to users, but only held that the company cannot control the price of a car after it has passed into the hands of a user who has bought it from an agent and paid the full price for it. The agent was therefore allowed judgment against the sheriff on the ground that the title to the car was in the company until it assigned it to the agent. (Whitney vs. Biggs, 155 N. Y. S. (New York) 1107.)



The two Day-Elder chassis in plain view. The Senior model appears at the left and the Junior at the right

Two Worm-Drive Day-Elder Trucks

Junior and Senior of Conventional Design—No Governor

PRACTICALLY the same structural features characterize two truck models which the Day-Elder Motors Co., Newark, N. J., is now producing. They are rated at 1250 and 2000 lb. capacity, known respectively as the D-E Junior and Senior trucks. Both are conventional designs, with rather low, rakish lines, Hotchkiss drive through worm gears and unit power plant assembly.

An outstanding feature is that both models are without governors, the smaller one being mounted on pneumatic tires and especially designed for fast delivery work, and the larger with solid tires. Both have small, high-speed motors, which should show economy in ordinary work, and yet, being of the high-speed type, they are able to develop higher power than if they were governed. In each model the engine is incorporated with the clutch and gearbox and suspended on three points, final drive being by single shafts with two universals each.

On the Junior model the Le Roi motor is used and on the Senior, a Continental. Both are block-cast with valves to the right and both have thermo-syphon cooling through square-tube vertical radiators in sheet-metal cases. Single high-tension ignition with hand spark advance is used on each model, both having Dixie magnetos. A Schebler carbureter is used on the Junior model and a Zenith on the Senior.

Left Steer and Center Control

Brakes are all on the rear wheels, consisting of side-by-side internal types, with rocking equalizers. Left steer and central levers are common to both models, Gemmer steering gears being used. Jones wheels are employed, the pneumatic-tired ones on the smaller model having demountable rims.

The Stewart vacuum system of gasoline feed is used, fed from cylindrical tank beneath the seat on each model.

Clutches and gearsets on both models are the products of the Detroit Gear & Machine Co., and comprise dry-disk clutches and three-speed selective gearsets. The shafts and universals are of Hartford make, driving Sheldon worm-driven axles. Both torque and propulsion are taken by the springs.

Prices as quoted in the specification table below apply to the stripped chasis only, including the driver's cab. Electric starting and lighting will be installed for an additional charge of $85, including the lamps. Standard bodies are carried in stock and will be applied at extra cost or the chassis will be sold without bodies.

In appearance the trucks are pleasing, the radiators being located well back on the frame in both models, behind the front axle in each case.

	Junior	Senior

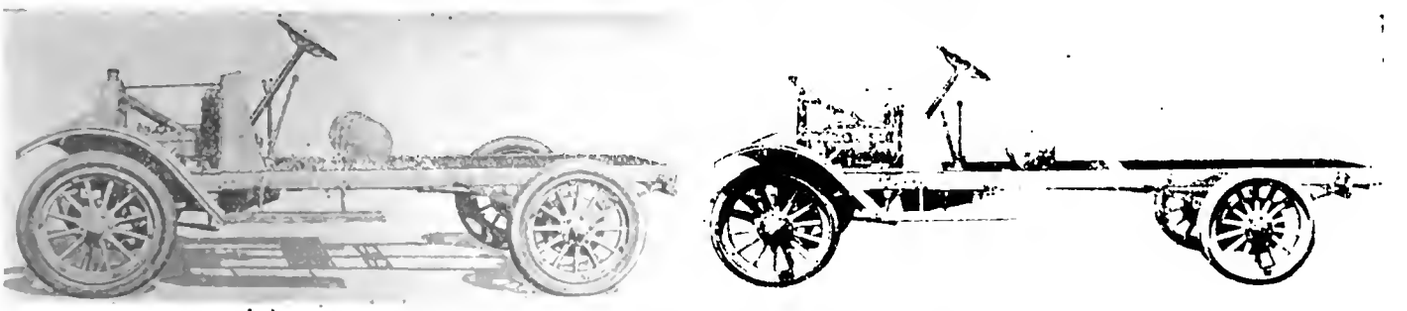
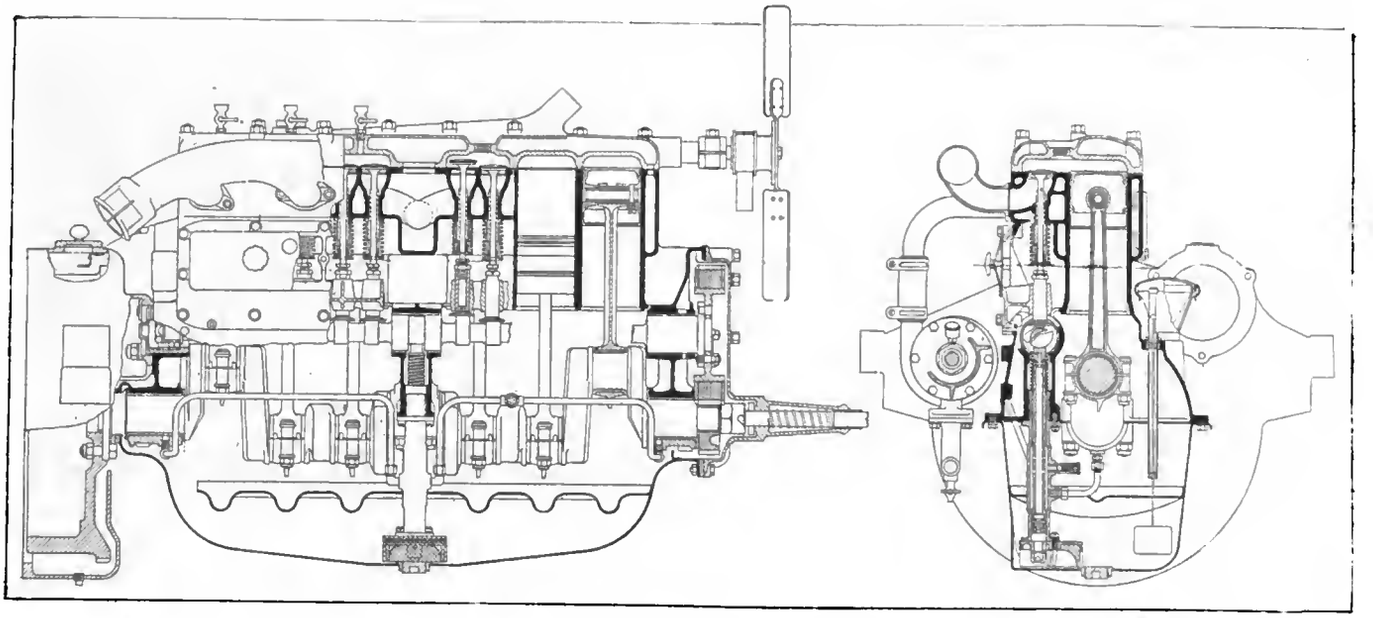
Some Simple Air Bag Precautions

A SUCCESSFUL western vulcanizer has found that he can save a great deal of money in the course of a year simply by being careful with his air bags.

The shape and inside dimensions of a Q. D. clincher tire are different from a straight side tire, so this vulcanizer has two sets of air bags, one for each type of tire. Tires of the same type but of different makes also vary in their dimensions but of course it would not be practical to have a different set of air bags for every brand of tires. To get around this difficulty the vulcanizer has pads of various sizes. —*Goodyear Tire News.*



Similarity of design marks the Day-Elder models. The Junior is at the left and Senior at the right



Longitudinal and transverse sections through the six-cylinder model 25 Rutenber engine. It has a bore of 3⅛ and a stroke of 5 in.

Rutenber Engines Made in Four Models

Two Are for Passenger Cars and Two for Trucks

RUTENBER engines, made by the Rutenber Motor Co., Marion, Ind., are made in four models. Two of these are for passenger cars and two for commercial vehicles. The bulk of manufacture in the plant is, however, given over to the model 25, which is used in the Paige, Auburn, Marion, Glide, Madison, Halliday, Roamer and Jones cars for the coming year.

This motor is a successor to the model 22 of last year and has been refined and rendered more powerful by an increase in the bore. In general design, however, it is very little different from its predecessor, what changes there are being due to the enlarged cylinder dimensions and in detail refinements. It is a six-cylinder L-head 3⅛ by 5 in.

The other passenger car engine is known as the model T. It is used in the Inter-State cars and is a four-cylinder, valve-in-the-head job, the dimensions being 3½ by 5 in.

Production on the truck models is limited by the fact that nearly all the facilities of the plant are required for the model twenty-five passenger car engines. The two truck models are fours and the entire consumption is taken by the Indiana Truck Co. The motors are known as the 38 and the 20 with dimensions respectively of 4⅛ by 5½ and 3½ by 5. They are standard L-head designs.

Crankshaft Is Larger

Regarding the improvements on the model 25, which is the focal point of Rutenber manufacture, there will be little fundamental change noted outside of what has been made necessary by the larger cylinders. The crankshaft has been strengthened and is now 2 in. in diameter in place of 1¾. The timing gears have been changed and are now Fabroid, or compressed Sea Island cotton, whereas in the former unit they were cast iron.

The oil pump is different and the drive for this unit has also been rearranged. While formerly a vein pump was used, the pump is now a plunger type, and while the drive was formerly off the front end of the camshaft, an eccentric has now been placed at the center camshaft bearing and the drive is taken from that. Another pump change is in the instrument for circulating the cooling water. This was formerly a separate casting bolted on to the crankcase. It is now contained directly in the case and a timing drive is fitted to it, to take the standard Remy units.

The fan pulley unit has been brought forward, allowing of a stiffer and thicker timing case. In the matter of motor fittings the engine is adapted to take any of the standard products. The flanges are so arranged that they can handle both vertical and horizontal installations.

All the makers who have previously been using the Rutenber model 22 and are continuing with the Rutenber product have shifted to the 25 without rendering necessary any important chassis changes. This makes the third successive year, practically, for this type of motor with the Rutenber concern. It is a six-cylinder four-cycle L-head design with the cylinders and the upper half of the crankcase cast together. Following up-to-date practice, the valves are inclosed and the cylinder heads are detachable. It is for unit or separate power plant construction designed for three-point suspension and having the flywheel bell housing as a detachable unit from the remainder of the engine.

The pistons are cast iron and are fitted with three rings. Two of these are close to the top and the third is located just beneath the wristpin boss, giving wide separation between the rings and reducing to a minimum the tendency toward slap. The wristpin is locked securely in the boss by a through set screw. I-beam connecting-rods are used and the crankshaft is a drop forging from 0.40 carbon steel made by the open hearth process. These shafts are all balanced in the Norton running balance machine and are passed on for balance before assembly.

For the camshaft 0.20 carbon steel is used. This is also a drop forging having a diameter of 1⅛ in. and the cams integral. The shafts are hardened and ground and are carried in plain bearings at the center and front and in an S. K. F. double-row, self-aligning bearing at the rear end.

The valves are actuated by mushroom type flat followers which are offset 1/16 in., allowing them to rotate while in operation and to distribute the wear around the peripheral

bearing surface. The valves are made in two parts with alloy steel stems and carbon steel heads. The diameter of the valves is 1 5/16 in. in the clear and the lift is 5/16 in. A feature of the valve construction is that the valve brackets, together with the entire lifter mechanism, can be lifted from the engine without disturbing the camshaft. This is done by removing the coverplate and stud nuts and then turning the starting crank until the valves are at their lowest level.

Standard Timing Used

Standard valve timing is used, and is in accordance with the practice on many of the latest American engines. The intake valve opens at 15 deg. after top center and closes 50 deg. after bottom center. The exhaust valve opens at 45 deg. before bottom center and closes 10 deg. after top center. Compression in 75 lb. absolute.

Provisions for Standard Electric Systems

Any standard starting and lighting unit can be employed with this engine. The flywheel ring gear as standard is cut with 126 teeth on an 8-10 pitch. The flywheel will fit any standard size clutch and the entire design is one which will fit in with the standardized chassis parts furnished by makers of clutches, gearsets, etc. An ignition distributer drive is mounted on the engine and can be used when desired.

Pressure and Splash Oiling

Combination pressure and splash feed is used for lubrication. The oil reservoir is in the bottom pan and has a capacity for 1½ gal. It is taken from the crankcase reservoir by the plunger pump, which, as has been explained, is driven by an eccentric off the camshaft. There are direct leads from the pump to the main bearings which thus receive a supply of oil under pressure. The other leads go direct to the crankcase where the oil is led to splash troughs placed beneath each connecting-rod throw. Provision is made for the mounting of an oil pressure gage and the pressure may be regulated by means of an adjustable relief valve. Some of the specifications of the model 25 engine follow:

Cylinders	Six
Bore	3½ in.
Stroke	5 in.
Valve diameter	1 5/16 in.
Piston length	3⅛ in.
Piston pin bearing	¾ by 1½ in.
Connecting-rod length	9½ in. center to center
Connecting-rod bearings	Front, 2 by 2¾ in.
Connecting-rod bearings	Center, 2 by 2¾ in.
Connecting-rod bearings	Rear, 2 by 3⅛ in.
Camshaft diameter	1⅛ in.
Camshaft bearings	Front, 1 15/16 by 2¾
Camshaft bearings	Center, 1 29/32 by 2⅞
Camshaft bearings	Rear, S.K.F. No. 1265
Length, front of fan to rear of cylinder	32¾ in.

Jeffery Quads with Wrecking Equipment for Mexico

A POWER winch, with 300 ft. of steel wire cable and two capstan heads, is the feature of a new type of wrecking truck that will aid the motor truck trains in Mexico when they get into difficulties. Several of these are now on their way south, and others are being turned out by the Thomas B. Jeffery Co., Kenosha, Wis., as fast as possible, in anticipation of the rainy season in Mexico. The chassis employed is the Jeffery Quad, which drives, brakes and steers on all four wheels. About 200 Quads for various purposes are already in Mexico.

Body Is of Steel

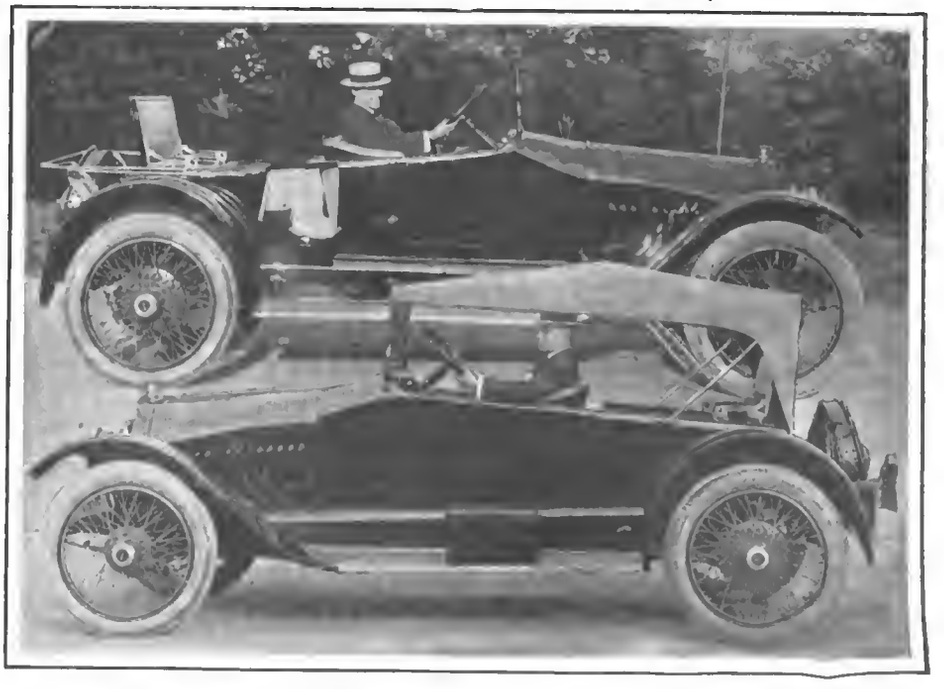
The body of this truck is made of steel. It is 10 ft. long, 40 in. wide and 32 in. deep, and has wide running boards on both sides, strong enough to hold a considerable outside load. Besides the power winch and capstan heads, the truck carries 300 ft. of 9/16-in. wire cable, 100 ft. of 1¼-in. manila rope, an oxy-acetylene welding outfit complete with acetylene and oxygen tanks, flux rods and wire. There is also a hand-operated derrick for lifting heavy objects into and out of the truck, besides a workman's bench with vice and tools. The auxiliary equipment includes shovels, axes, crowbars, pick-axe, sledge hammers, gin pole, tow chain, wheel and flange pullers, clamps, files, and a Pyrene fire extinguisher.

A Special Five-Passenger Design On Mitchell Chassis

AT the right is illustrated a five-passenger roadster specially designed and built by the Carl H. Page Motors Co., New York City, agent for the Mitchell on which chassis the body is mounted. The rear portion can be closed entirely, thus converting the car into a two-passenger roadster while when opened it has ample room for five, the seats being large and comfortable, the fifth seat being formed by the door on the right-hand side which also serves as an entrance to the rear seats.

Top Disappears

As shown in the illustration the top is of distinctive construction, the top material being removable so that when the top is not in use the nickel-plated bows are folded down around the rear of the body, the material being compactly stowed away in a receptacle especially provided for it at the back of the body.



The Search for the Army Truck Wheel

(*Continued from July 6, pages 24-26*)

By Marius C. Krarup

SINCE the normal driving wheels of automobiles and motor trucks are the only working elements in them whose operation depends on friction, and particularly on friction with a road surface of uncertain and variable suitability for acting as the corresponding friction element, the examination of other types of wheel, with the idea of arriving at a preliminary idea of their properties in advance of actual tests or to decide if practical trial would be advisable, should be liable to save costly experiments sooner or later. In the case of the composite type of wheel—which might also be termed the "squirrel cage" or "treadmill" type, to suggest its mechanical nature more graphically—no such preliminary examination has appeared in public, while it is known that the type has been used in practice and has shown some very desirable qualities (especially in negotiating sandhills and ravines with heavy loads), but also that it has not survived and that probably, therefore, some sharp limitations of its utility have cropped out. The nature of these has not come to light, however, and they may have arisen from faulty application or design rather than from unavoidable defects in the principle.

In so much more as the cursory examination of the same type for front wheels and trailer wheels in THE AUTOMOBILE of June 22 indicated considerable merit for this mode of using it, the more intricate examination of its possibilities for driving wheels seems to be in line with the many efforts now being made, partly in connection with the European war and partly in the development of farm tractors, at finding a wheel type which will operate where normal wheels are unreliable. An examination of this kind may lead to practical trials or to rejection of the type. It can scarcely be sufficiently decisive and explicit to compel acceptance of its purely theoretical conclusions, as the subject is probably still more complicated in practice, but these should of course be as nearly correct as possible in the essentials.

Correction of Errors

As intimated in a note at the end of last week's instalment of this article, however, an error in the premises for the equations in it was scented by the writer too late for correction in that issue, which was then going to press. Subsequently another error was discovered, consisting in applying the gravitation formula for the time of the free fall, $t = \sqrt{2h:g}$ or, approximately, $t = \frac{1}{4}\sqrt{h}$, in connection with measurements expressed in inches, and this slip affected the figures materially. The safe maxim of not doing new work hurriedly was thus unfortunately vindicated, and the writer must ask readers to replace the matter from the first equation near the top on page 25 to the end on page 26 with a more correct version, as given in the following, the passages in small type being substantially repetitions explaining the method of reasoning and not materially affected by the errors in the details.

It was erroneously supposed that the factor p was needed to indicate the nature of the road, but more deliberate examination of the work of propulsion shows that, if traction resistance is uniform, p does not stand for anything that is not fully expressed in coefficient f. The equations should therefore be remodeled by eliminating p, or else giving it the value 1 unless the physical conditions under consideration include an unyielding obstruction imbedded in a soft road and it is the special object to determine how such an obstruction affects the propulsion. It is simpler to eliminate p in considering a uniform traction resistance and introduce it again only where it belongs.

In restating the case, Fig. 3 is reproduced for renewed reference herewith. For completeness, front wheel resistance is also included in the subject and the equations, while previously it was made an after-consideration.

Angle α represents the minimum advancement of Q necessary for producing vehicle movement through the turning of Y. The pressure of L at b balances under this supposition against the traction resistance. The latter is expressed by coefficient f as a percentage of the weight to be moved. When the application of power to Q holds this component of the wheel forward and in contact with the other component, Y, at b, the load L, acting vertically at this point tends to turn Y around the point of ground contact, A, the resistance being primarily $(L + W)\,f$; where W is the weight of Y. But, if the resistance to the simultaneous turning of the front wheel is included, and the load thereon is L_2 (including the weight of the wheel itself), the total resistance to be balanced by L acting at b is $(L + W + L_2)\,f$. As the movement to be effected is the (continuously repeated) turning of Y around A, the required action is analogous to that of a pair of scales with arms of unequal and variable length. The power acts with pressure L and the leverage $R \sin \alpha$. The weight to be moved may be considered as acting with an opposite leverage just sufficient to balance against this pressure, any increase of angle α causing movement. One has then

$$L\,R \sin \alpha = (L + W + L_2)\,f.$$

Whether the road is hard and smooth, in which case f becomes small, or it is soft, so that the wheel is imbedded in it to some depth, the value for f in each case expresses the degree of resistance caused by the road condition, and no additional factor is needed to express a road condition under which the wheel's contact with the ground extends more or less on both sides of A. A remains the pivot around which Y must turn progressively, so long as the traction resistance is not rendered irregular by unyielding, imbedded or projecting, substance.

To determine how large α must be, one has therefore

$$f = \frac{L\,R \sin \alpha}{L + W + L_2} \text{ and } R \sin \alpha = \frac{f\,(L + W + L_2)}{L}$$

As L_2 is rarely more than one fourth of L, and W is small, say 5 per cent of L, one has then, even if f is taken as high as 20 per cent and with $R = 15$ in.,

$$\sin \alpha = \frac{20 \times 1.30}{1500} = \frac{26}{1500} = 0.0173$$

making α a very small angle. Movement of the vehicle therefore begins on a level road, even if it is so sandy or soft as to raise f to 0.20, at a very small advancement of Q.

In the case of a steam vehicle or a gasoline motor truck with hydraulic transmission, these relations should be decisive to show that the composite driving wheel system will permit starting and operation at one speed or another. But for ordinary gasoline motor trucks the practical question relates to starting and running at the speed giving maximum torque for driving wheel Q, and this is the speed obtained on low gear with the motor running at normal speed. It may be 3 or 4 m.p.h. Let it be given as m m.p.h. vehicle speed. The question is then: At m m.p.h. what are the limit values for β and f? (β being the angle, larger than α, at which a desired vehicle speed is produced.)

To avoid considering the initial acceleration of the vehicle at the

sion is indicated by the line X, this is given as 38 in., which will accommodate the average person, the distance of 4 in. from back of the wheel to the back line of the door will allow a 10½-in. opening between wheel and body, but as the majority of people enter from the curb side, this is not so vital on a left-drive car, and on Fig. 1 this distance is less, the door being 19 in. in width.

Trimming Should Be Leather

These bodies are trimmed in leather, the seats and backs being of generous thickness and very comfortable. No trimming appears above the body or seat line, the doors have the customary flap pockets and the floor is linoleum covered. Locker space is provided under the seats if possible and the rear compartment has a cover on the top as shown.

The present tendency in color design is about equally divided between the somber shades and gay color. Of the first blue predominates and of the light colors, yellow or yellow and black, white and black, various shades of gray from light to dark and a few reds. If wire wheels are used, they are frequently made to show the contrast in color, black wheels being used with all shades of light colored bodies and the wheels are the only contrast, the guards being of the body color.

The great popularity of the clover leaf style of body, predicted in the summer of 1915 and emphasized by the shows of the early 1916 season, is certainly being upheld, at least in the large cities. The clover leaf is essentially the body for a man who likes a smart appearing car and its chief attraction is that it can have the lines of a racy roadster and yet have a greater capacity. If the rear compartment is not used for passenger accommodation it is often extremely useful for baggage and for carrying golf clubs or other sportsmen's impedimenta. The long aisle provided by the passage between the two front seats is more convenient than even the whole tonneau of a five-passenger car of conventional design.

Type Likely to Persist

Thus there is good reason to expect that the clover leaf or something very much like it should be regarded as a permanent addition to automobile body styles. If its appearance should go out of fashion, if its lines should cease to seem to be as smart as they now appear, still the convenience of the seating plan should hold that part of the design unchanged. Almost any kind of an outer shell can be arranged around a pair of seats of the clover leaf type, in fact the body lends itself to more variation, almost, than any other. That this is true is shown by a study of the very large number of quite different styles produced within the past twelve months.

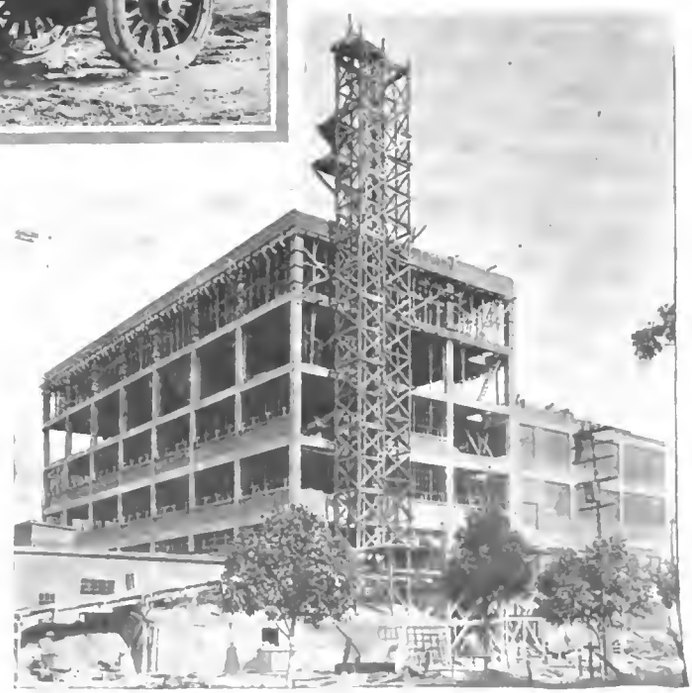
F. W. D. Repair Truck for U. S. Army

ABOVE is illustrated one of the repair trucks built by the Four Wheel Drive Auto Co., Clintonville, Wis., for use by the United States Army. These trucks are fitted for repair work on the road and are expected to prove extremely valuable in keeping the trains of supply trucks in good mechanical condition. Each truck is equipped with a 13-in. lathe with a 5-ft. bed; a drill press; grinder; portable drill; cabinet bench; three vises; a forge; three anvils; oxygen-acetylene welding outfit; a complete set of blacksmith's tools and also complete sets of machine bench tools and carpenter's tools.

A 9-hp. four-cylinder gasoline engine drives the dynamo which furnishes power to the motors which operate the various machines and also supplies the current for the electric light. Oxygen and acetylene tanks are carried under the frame of the truck where they are accessible but do not take up valuable space.

Champion Adds Again

THE Champion Spark Plug Co., Toledo, Ohio, has again been obliged to expand its factory facilities by the addition of the six story building illustrated in course of construction below. In this new structure the company can turn out from 75,000 to 100,000 spark plugs a day and from 1400 to 1500 employees will be engaged in their manufacture, from this time onward.



Pneumatic Tire and Rim Situation

Early Development of the Various Types of Demountable and Detachable Rims—Comparing the Three Types of Tires—Cost of Operation, Reliability—Future Possibilities

By J. E. Hale
Experimental Engineer, Goodyear Tire & Rubber Co.

BY 1907 the detachable rim with a straight-side tire had become so much appreciated by the public that the clincher-tire manufacturers were obliged to furnish some sort of a detachable tire. The result was the quick-detachable clincher tire called the Q. D. clincher. The introduction of this tire was facilitated by the simultaneous introduction of the universal rim, which would take either a straight-side or a clincher tire by simply reversing the side rings.

While the quick-detachable clincher was a half-way compromise between the clincher and straight-side types, its introduction at that time was justified because the tire-building art was in a stage of development, not having progressed to a point where everybody was producing a successful straight-side tire. Up to the present time the straight-side, clincher and quick-detachable clincher tires have been exploited by their respective backers, and competition has stimulated development of each type. The basic structure of the pneumatic tire has not changed (except by the developments in cord tires) since 1907. The rim details have, however, been undergoing constant progressive development.

Rim Development

In 1911 the demountable rim began to receive commercial attention. In 1912 several manufacturers put them on cars as original equipment. The demountable rims were soon widely demanded by the public, which of course stimulated their further development. The early demountable rims were heavy. Competition has brought many new light-weight designs, some of which have been carried to such extremes that tire troubles result.

The preceding refers to American practice. In Europe the detachable rim and tire did not succeed in getting a foothold, so that as the industry expanded the use of the soft-bead clincher and one-piece clincher rims became firmly established. In Europe four circumstances saved the clincher from the competition of the detachable tire. First, rim-cutting, the worst trouble of the clincher tire, was mastered early. Second, the majority of car owners in Europe have chauffeurs who change the tires, which amounts to saying that a little saving in tire-applying effort does not interest them. Third, it is rather difficult, especially in England, to introduce new contrivances in competition with those firmly established. Fourth, the demountable wire wheel was one of the early developments in European automobile practice. Its use has been extended widely, so that if the quick tire-change idea had to be met, it was considered that the demountable wheel was satisfactory. There were no champions of the detachable type in Europe similar to those in America.

Need for European Sizes

In South America, Australia and South Africa European cars have predominated; naturally the use of millimeter-size (European) tires and rims is firmly established. However, during the recent period of trade activity by American manufacturers many inch-size clincher tires and rims have been introduced in these fields. This is most unfortunate because inch-size tires will be used on millimeter rims if the proper millimeter-size tires are not in stock, with certainty of rim trouble. The same thing is true of the application of inch-size tires on millimeter rims. This foreign business is expanding to such volume that the dimensional clincher-tire complication will, unless checked, ultimately react severely against American prospects. American car makers must discontinue the use of inch-clincher (except Ford sizes) and adopt either the millimeter clincher or inch-size straight-side types.

The straight-side tires are the logical solution. Why should car manufacturers continue to complicate their production processes by equipping some of their cars with millimeter clincher tires and others with straight-side tires, when by proper co-operation between the tire and car makers, the straight-side type, fully perfected and standardized, can be introduced quietly into these markets?

The refinements accompanying the intensive development of the motor car have reached a point where even the weight of the light demountable rim is regarded with disfavor. A return to the simple light-weight detachable rim fitted directly to the felloe of the wheel seems likely. The car designers want to eliminate weight, particularly unsprung weight, at the periphery of the wheel, and to reduce the cost; the car owner desires a maximum of tire service with a minimum of tire trouble. Thus the situation boils down to a case of the survival of the fittest with the demountable rim, the demountable wheel and the simple rim mounted on a permanent wheel on the one side; and the straight-side tire, the clincher tire and the quick-detachable clincher tire on the other.

Three Types of Tires Compared

The purpose of this paper is to point out the trend of the time in the tire world, and to venture a prediction concerning the future. In order to lay proper stress on the points to be brought out, it seems wise to discuss the merits of the three types of tires under the following headings: Energy consumption; traction; total mileage; cost per tire-mile; cushioning effect; reliability; ease of applying; and service.

Figs. 2, 4 and 8 show the straight-side, quick-detachable clincher and soft-bead clincher tires that will be compared. These are drawn to scale. The straight-side tire is shown on the wide standard rim. All three tires will be identical in every particular above the line *H-K;* consequently the energy consumption and traction would be the same for each type.

Factors Affecting Total Mileage

The total mileage would be influenced by the structure of the tire below the line *H-K*. While the schemes of attachment to the rims have been largely perfected, the life of the tire is sometimes shortened by a form of trouble com-

monly called rim-cutting. In a well designed and properly built tire the chances of rim-cutting troubles from causes inherent in the tires themselves are remote. Imperfect rims and various forms of abuse are the actual causes. If a tire is punctured and ridden flat, the clincher casings and tubes will soon be ruined beyond repair. The clinch of the rim simply gouges into the carcass of the tire and cuts through the plies. At the same time, the tube gets under the toes of the bead, which mutilates it beyond repair. The structure of the straight-side tire, on the other hand, is such that the carcass is simply crushed against a comparatively wide rounding surface. Of course, the straight-side tire and tubes can easily be ruined by this form of abuse, but the chances are three to one in its favor, compared with the other type. The effect of the quick-detachable clincher is about half way between that on the clincher and straight-side tires. In this case the toes of the bead do not lift to catch the tube, but the clinch of the rim gouges into the fabric of the casing to some extent.

Under-Inflation and Overloading

These are similar in their effects on the structure of the tire, being forms of abuse that aggravate any tendency to rim-cut. The effect is more pronounced on the clincher type than on the straight-side, because the flexing of piles is localized at the edge of the clinch with the former, while with the latter the flexing is distributed with less intensity over the gradual curvature of the rim.

Tire-Mile Cost of Operation

The cost per tire mile is of course a function of the mileage and of the original cost of the tire. Inasmuch as the three types cost the same, the tire-mile cost is directly proportional to the mileage. Since the tires of the different types are alike above the line *H-K*, the service will average the same for all so far as the upper part of the tires is concerned. Any variation in the tire-mile cost will be dependent on the complications introduced by tire-base troubles. While no specific cost figures can be presented, there is no doubt that the tire-mile cost of the straight-side tire is the lowest. This is strongly emphasized by the domination of the straight-side over the quick-detachable clincher tires as shown in the percentages given in Table I.

TABLE I—TIRE EQUIPMENT (IN PER CENT) ON CARS PRODUCED 1913-1916

Type of Tire	1913	1914	1915	1916
Straight-Side Equip.	32	72	84	96
Quick-Detachable Clincher Equip.	40	28	16	4
Universal Rim	28	.....	.....	.....
Total	100	100	100	100

Cushioning Effect

For a given tire section the cushioning effect is largely dependent on the relation between the load and inflation pressure. Lowering the inflation pressure gives the greater cushioning effect, but on the other hand fabric troubles are greatly increased by excessive flexing of the carcass. In practice it has been found that the best inflation pressure will permit the tread to be depressed 11 to 12 per cent of the tire section. Since all three types are alike above the line *H-K*, the cushioning qualities are the same if the tires are operated under similar conditions.

Scope of Reliability

The difference in the rim-attachment structure of the two types has an effect on the cushioning properties. A straight-side and a quick-detachable clincher tire of the same size and design to require the same quantity of raw materials, are superimposed in Fig. 1. This shows that the straight-side tire has the advantage due to the beads of the tire being more widely separated, resulting in a slightly larger diameter of tire section.

Reliability covers such features as freedom from instantaneous failures and safety considerations. Punctures, blowouts and fabric breaks occurring in the tread and side-wall portion of the carcass (above the line *H-K*) are on a par in all three types. Fabric failures at the point of contact with the rim are apt to be more in the nature of a concealed distress followed by sudden failure (blowout in effect) in the clincher and quick-detachable, while the corresponding troubles with the straight-side tires are easier to detect and provide against.

Blowing Off the Rim

Blowing off the rim is one of the troubles of bygone days. The early straight-side tires had a good many black marks against them on this account and clincher tires are still occasionally subject to this annoyance. This condition was one of the prime excuses for the introduction of the quick-detachable clincher tire. Because some of the early straight-side tires blew off the rim, certain car makers concluded that this type was not safe. It was not appreciated universally that the straight-side construction is a purely mechanical method of attachment and independent of inflation pressure. At the same time the detachable idea was so meritorious that all tire manufacturers were compelled to put out some sort of a "detachable" tire. Inasmuch as the soft-bead clincher had represented the best practice in was natural to combine the inextensible bead of the straight-side with the clincher idea in an attempt to provide a detachable tire that would not blow off the rim. In the undeveloped state of the tire-building art it was felt that in order to be perfectly safe a tire must hook under the clinch of a rim. The later development of the straight-side tire has, however, shown conclusively that the problem of safety was simply one of designing the tires to have proper strength at the weak point, so that at present, for every several hundred that fail by rim-cutting and blowouts, only one tire blows off the rim.

TABLE II—TIRE AND RIM EQUIPMENT ON CARS PRODUCED 1913-1916

	1913		1914		*1915		*1916	
Type	No. Cars	Per Cent	No. Cars	Per Cent	No. Cars	Per Cent	No. Cars	Per Cent

TABLE III—SOFT-BEAD CLINCHER TIRES AND ONE-PIECE CLINCHER RIMS ON 1916 CARS

Name	Tire Sizes		Name	Tire Sizes	
Bell		3½	Monroe	3	3
Briscoe		3½	Metz		3½
Chevrolet	3	3½	Regal		3½
Dort		3½	Overland		4
Elco		3½	Pullman		4
Ford	3	3½	Scripps-Booth		3½
Maxwell		3½	Sphinx		3½

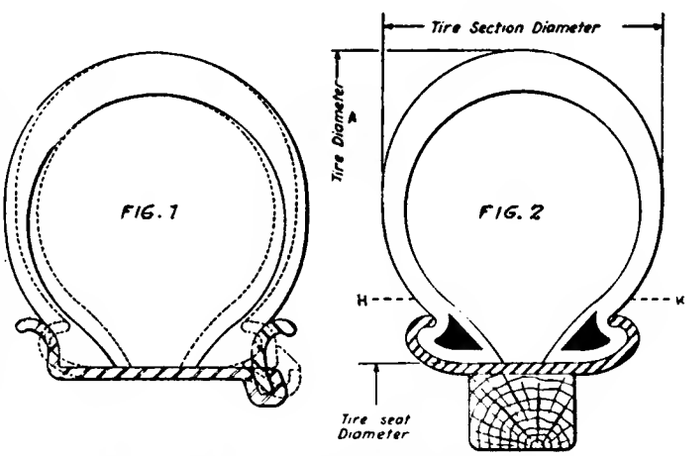

Fig. 1—Straight-side tire (full lines) superimposed on quick-detachable clincher tire (dotted lines). Fig. 2—Soft-bead clincher tire mounted on one-piece rim

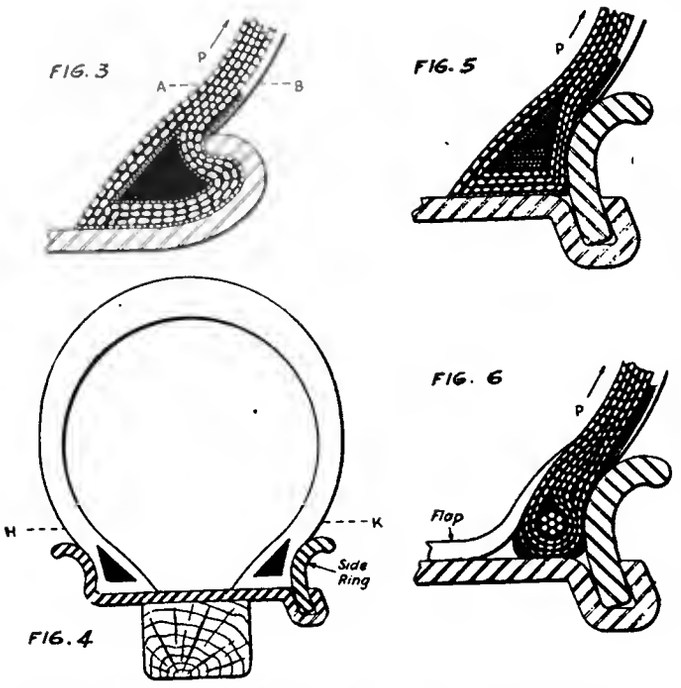

Fig. 3—Details of clincher rim and bead. Fig. 4—Straight-side tire mounted on two-piece detachable rim. Fig. 5—Inextensible braided-wire bead. Fig. 6—Inextensible twisted-wire bead

How completely the straight-side tire has lived down original prejudices is evidenced by the fact that 529,000 new cars will be delivered on straight-side tires during the 1916 season.

Ease of Applying

The 3-in. clincher tires are no more difficult to remove and apply than the other types, but beginning with the 3½-in., each larger size is correspondingly more difficult to handle. In applying the quick-detachable clincher tires the bead needs considerable coaxing to get it properly seated under the rim clinch; and the carcass of the tire is often so stiff as to make it difficult to slip the locking ring into place. This is especially true with the oversize tires. The quick-detachable tire is frequently found to be frozen to the rim by rust, thus requiring much effort in removing it. This tire on a split rim is really a formidable proposition; application is difficult and removal almost impossible.

Table IV—Straight-Side Tires on 1916 Cars

Name	Tire Sizes			Name	Tire Sizes		
Abbott		4	4½	Jackson		4	4½
Allen	3½			Jeffery		4	4½
Alter	3½			Jones		4

Hudson			4½	Sun		4	
Hupp		4		Overland		4	4½
Interstate		4		Velie		4	

Service refers principally to the distribution of the sizes required by the trade. Owing to the extreme flexibility of the movements of the automobile, competition forces dealers to carry all the sizes in demand in clinchers, quick-detachable clinchers, and straight-side types.

Early in this paper it was stated that the tire and rim questions boil down to a question of the survival of the fittest. The statistics in Table II show very decidedly the trend.

It is just a question of time until the quick-detachable clincher will become eliminated. This tire had a legitimate place during the period of development, but with the straight-side tires giving entire satisfaction, there is no excuse for continuing the former type. Dealers have to carry the three kinds of tire with many sizes common to each type. With the quick-detachable clincher eliminated, nearly one-third the stocks could be discontinued, which would mean correspondingly better service on the other two types, less capital tied up in stocks, greater incentive to carry all sizes, and ultimately less expense to the whole industry, and more simplified production.

Tire Equipment of Various Makers

To further explain the situation, I have prepared the Tables III, IV and V (from published information), showing by size and type the tire equipment used on the principal cars. Pneumatic-tired trucks are not included.

The total estimated production in 1916 is 601,000 cars using clincher tires and one-piece clincher rims. This estimate applies to the fourteen makers listed in Table III.

Table V—Quick-Detachable Clincher Tires on 1916 Cars

Car	Tire Sizes		Car	Tire Sizes		
Cunningham	4½	5	Pathfinder		4½	
Fiat	4½	5	Pierce		4½	5
Locomobile	4½	5	Premier		4½	
Marmon	4½		Stanley		4½	
McFarlan	4½		Stearns	4	4½	
Mercer	4½		Stutz			5
National	4½		White	4	4½	5
Packard	4½	5	Winton		4½	
			Westcott	4	4½	

The total estimated production in 1916 is 529,000 cars using straight-side tires. This estimate applies to the fifty-two makers listed in Table IV.

The total estimated production in 1916 is 22,000 cars using quick-detachable clincher tires. This estimate applies to the seventeen makers listed in Table V.

From the three groups tabulated we observe (1) Clincher tires are confined to 3 and 3½-in. sizes. (2) Straight-side tires are used in 3½, 4 and 4½-in. sizes. (3) The quick-detachable clinchers are confined to the 4, 4½ and 5-in. sizes.

Concluding Comments and Predictions

The pneumatic tire has passed through its evolutionary stages. Future developments will be confined to refinements intended to eliminate the common tire troubles, and to increase the tire mileage.

The American standard inch clincher-rim contours, the British standard millimeter clincher-rim contours, and the American wide standard inch straight-side rim contours will undoubtedly survive all others.

Outside of the contours, however, rims are still in process of evolution. In the struggle to minimize weight, expense and tire troubles the existing demountable types may lose ground, particularly as the light-weight one-piece clincher and the two-piece straight-side rims, either on permanent or detachable wheels, apparently offer the next step forward.

Extra Types Will Be Eliminated

We now have uneconomical duplication in sizes in three types of tires performing similar service, but the law of natural selection will effect the elimination of the unnecessary types. Probably clincher tires (in America) will be confined eventually to motorcycle and 3 and 3½-in. automobile tires. Straight-side tires will be used in some 3½-in. and in all larger sizes. The quick-detachable clincher will shortly disappear from use.

The export markets in absorbing American cars will assimilate American constructions more and more readily. Straight-side tires will be introduced into these markets dur-

ing the coming season as original equipment on some American cars. This type will presently be appreciated as much abroad as it is in America. Thus we are to initiate a step that will result ultimately in a single world-wide standard for pneumatic tires and rims.

Figs. 2 to 11 are inserted for the benefit of persons desiring more detailed information on tires and rims.

The base portions of the tire in Fig. 2 have sufficient elasticity to permit their being stretched and pried over the the edges of the rim when applying and removing it. The extensible bead core is made of semi-hard rubber.

The bead in Fig. 3 is understood to be the entire portion of the tire below the line *A-B*. The bead core is made of semi-hard rubber, which has just enough stretch to allow it to be pried over the rim. The tires are made about ½ in. smaller than the tire-seat diameter of the rim. This insures a snug fit against the rim and prevents the tube from pinching.

The internal bursting pressure of the air sets up stresses in the direction indicated by arrow *P*. These stresses are resisted at the hook of the clinch. In other words, a soft-bead clincher tire in its functioning is positively dependent on the air pressure to maintain its shape and position.

In Fig. 4 the side ring is cut in one place and can be removed by prying out with a screw driver. Figs. 5, 6 and 7 show enlarged details of three prominent types of straight-side beads. Each bead is made inextensible by an endless reinforcement of braided wire (Fig. 5), twisted wire (Fig. 6), and wire cables (Fig. 7).

In the type shown in Fig. 7 the fabric plies are tied under the inextensible reinforcing wires; thus the side wall stresses (*P*) are transmitted from the carcass fabric to these circumferential wires. It will be seen that a strictly mechanical method is used to fasten the tire to the wheel in contrast to the soft-bead clincher method, which is analgous to the action of an elastic band. The inside diameter of the tire is slightly greater than the corresponding rim diameter (1/32 to 3/64 in.), which permits the tire to be applied and removed easily.

While the chance of pinching tubes under the beads of straight-side tires is remote flaps are used in the larger sizes, as a precaution.

In the quick-detachable clincher rim, Fig. 8, the side ring is endless while the locking ring is cut in one place. In removing the base of the tire and the side ring embracing it must be crowded bodily toward the center of the rim far enough to clear the inner edge of the locking ring. The locking ring can then be removed by prying out with a screw-driver, after which the tire and the side ring can be removed.

Figs. 9, 10 and 11 show enlarged details of the bead structure of the quick-detachable clincher tire. By comparing Figs. 5 and 9 it will be appreciated readily that Fig. 9 simply shows a straight-side tire with the addition of a clinch filler. This clinch filler is not tied into the body of the bead (by gripping with pliers the whole filler can easily be torn off the tire); consequently it is of absolutely no value in helping to hold the tire in the rim. Its real function is to fill the void that would otherwise exist.

Fig. 11 compared with Fig. 6 shows a similar situation, except that the outside ply of the carcass is laid so as to include the clinch filler. In Fig. 10 the quick-detachable construction closely resembles the regular soft-bead clincher construction. In this case, however, the bead core is made of a mass of cords impregnated with hard rubber extending circumferentially around the tire. The bead of this tire is really semi-extensible.

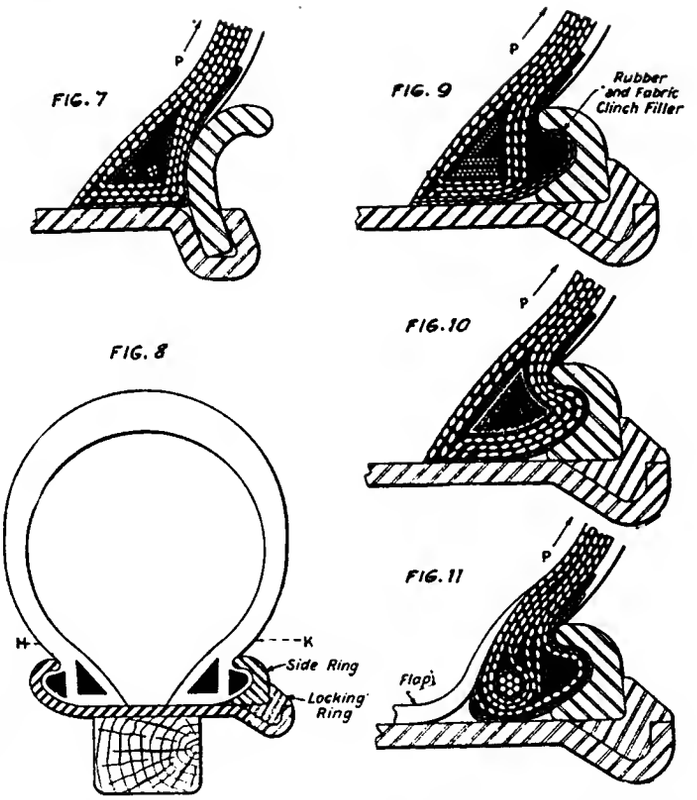

Fig. 7—Inextensible wire-cable bead. Fig. 8—Quick-detachable clincher tire and rim. Fig. 9—Inextensible braided-wire bead on quick-detachable clincher tire. Fig. 10—Bead of parallel cords on quick-detachable clincher tire. Fig. 11—Heavy wire bead on quick-detachable clincher tire

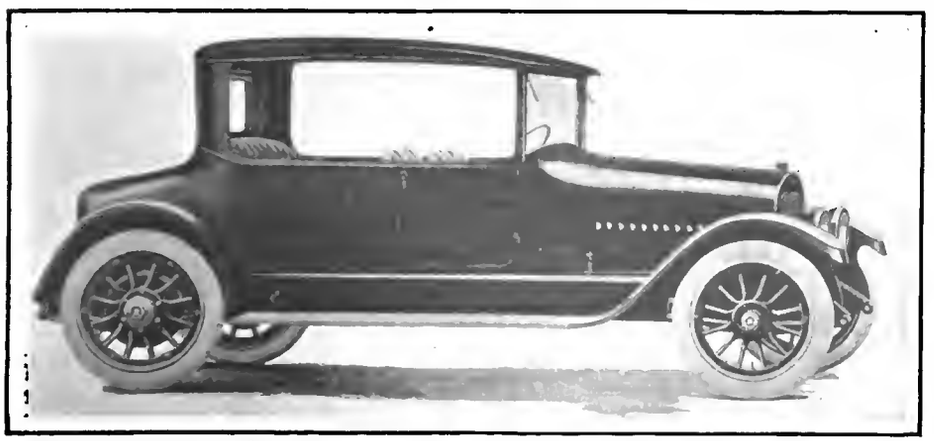
The New Cole-Springfield Body Types



AT the left is illustrated the new Cole-Springfield body, which, fitted to the standard eight-cylinder Cole chassis, is styled the Tourcoupé and sells for $2,195. This is one of the new group of all-weather type bodies announced last week by the Cole Motor Car Co., Indianapolis, Ind., the other models consisting of the Cole-Springfield Toursedan, which is a seven-passenger car meeting the requirements of both touring car and limousine and selling at $2,195, and the Towncar listed at $2,492. These bodies are luxuriously fitted out, being finished in American flag blue with dull black trimming and mouse gray upholstery. There are automatic electric door lights and light switches are located both at the driver's seat and in the tonneau.

Miller Differential Has New Motion

Frictional Resistance to Free Differentiation in Proportion to Tendency to Spin—Free for Turning Corners Yet Stiff Against Spinning

IN these days it is not often that a patent is granted for a new mechanical motion, as almost every conceivable sort of mechanism has been used for one purpose or another. However, the inventors of the Dorr-Miller differential have obtained such a patent in addition to their main patent for an entirely new differential mechanism.

Like many differential devices the Dorr-Miller is hard to describe, though its action can be grasped quickly when a model is held in the hands, so it may be best to explain firstly what it does and secondly how it does it. What it does is to differentiate with perfect freedom as long as there is no driving pressure on it, to tighten up as the driving load increases, and to tighten up in proportion to any and every tendency to differentiate when the driving force is constant. In other words the more the circumstances of the road and driving effort endeavor to produce wheel spinning, the more does the device compensate for this tendency by interposing frictional resistance.

Friction in Proportion to Load

The reason for this action can be expressed loosely as follows: There are two disks forming the two halves of the differential with the special mechanism between them. These disks and the mechanism are contained within a differential case of the usual sort made of steel. The action of the driving force of the engine tends to spread the disks apart, so causing them to press upon the inner walls of the case. When running straight ahead case and disks revolve solid, just like any other differential, but when one wheel tries to turn faster than the other its tendency is resisted by the friction of the disks pressing on the inside of the case. This means that, when outside circumstances accelerate one wheel the internal friction tends to slow that wheel down or to accelerate the other wheel, which is equivalent to saying that the friction causes both road wheels always to try to turn at the same speed. If one wheel is jacked off the ground and the engine started in gear, the raised wheel will revolve freely just as with the conventional type, but the slightest resistance offered to the free wheel, the least touch of the brake for example, immediately transfers torque to the wheel resting on the ground and the car rolls off the jack. This is because the resistance causes the two disks to spread apart, whereupon they rub against the inside of the differential case and the frictional drag caused by a light resistance applied to the free wheel is enough to cause the locked wheel to move the car. With the clutch out the differential is just as free and differentiates just as perfectly as any other type.

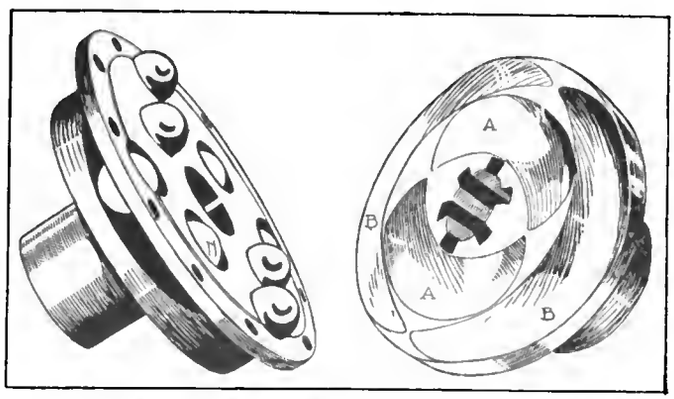


Fig. 1—Sketch to explain action of Dorr-Miller differential

Ball Forms Grooves

Now to describe the mechanism by which these results are obtained. Referring to the sketch Fig. 1 the two disks are seen on right and left. Each disk has grooves cut in the face, *A* and *B*, and these grooves are deep and wide at the middle of their length, tapering off at each end. The form of these grooves may be pictured by taking a ball and rolling it along some plastic material like putty. Rolled gently it will make no mark but if pressure is applied it will sink in, going deeper and deeper as the pressure is increased. Imagine the pressure increased regularly until the ball was buried for a depth of half its diameter and then released again till the ball once more rolled up on the flat surface of the putty, and you would have a straight groove exactly like the curved grooves cut in the Miller differential disks.

Having got the disk, imagine a plate with four holes in it, each just large enough to hold a ball of the same size as the ball with which the grooves were generated. Stand the plate on the disk with a hole opposite the center or deepest part of each groove and drop in four balls. Then, if the groove is half the ball diameter deep and the plate is as thick as the groove is deep, the four balls will lie in the holes and will just come flush with the face of the plate.

Effect of Turning Plate

Now turn the plate around upon the disk and each ball will roll along its groove till it reaches the end and, as it rolls along, it will rise through the hole in the plate till it no longer engages the groove (having come to the end) but stands half projecting from the hole. In the sketch the plate is shown with eight balls, four being at the centers of the grooves and four at the ends.

Next, continue the turning of the plate and the four balls which were standing out will begin to sink down again into the next groove. In other words the outer grooves *B* and the inner grooves *A* guide the balls just as though they were running in a ball thrust bearing, with the difference that the balls reciprocate to and fro through the holes in the retaining plate.

But so far we have considered only one disk and the plate. The other disk has corresponding grooves and, if we imagine it placed on the plate as shown in the sketch, the grooves will be at right angles to those in the left hand disk. The balls which are standing half way out of the plate as sketched will just fit in the centers of the grooves in the right hand disk.

Having thus assembled the essential parts think what will happen if the plate in the middle is revolved while an equal resistance is applied to each of the two disks. The ball which is at the bottom of the groove in one disk cannot rise through the hole in the plate because it is opposite the neutral point between the grooves in the other plate, and this applies to each of the eight balls. Thus the two disks will turn with the plate, all three at the same speed.

Balls Expand Differential

Now, another thing that is obvious occurs. Each ball is trying to roll along its groove, when the center plate is

turned, and it is prevented from doing so by the opposite disk which prevents it from rising through the hole. This causes a thrust or spreading action tending to force the disks apart. But there is a case around both disks to which the bevel drive gear is bolted, precisely as with the conventional differential, so the back of each disk is pressed against the interior of the case behind it and the harder the driving pressure on the plate the harder will the disks try to separate and the harder will they press on the walls of the case. Which explains how the frictional resistance to differentiation increases as the driving effort increases.

How It Differentiates

So far so good, but perhaps it is still not clear how the device can differentiate at all. To follow this action suppose that we stand one disk on the table, put the plate and the balls in position just as in the sketch and then place the other disk on top. Now, leaving the center plate free, turn the upper disk. This causes the upstanding balls to act like dowel pins in the plate and so makes the plate move forward in the same direction as we are turning the upper disk. As soon as the plate has moved, the upper balls will begin to run down into the grooves in the lower disk and the lower balls to rise up into the grooves of the upper plate. The balls act exactly like the planet wheels in a bevel differential and the center plate will revolve at *half* the speed of the disk we are turning. Of course this action can be reversed, that is if we turn the center plate the free, upper disk will revolve at *twice* the speed of the plate.

If this experiment is tried with the parts as shown and with no case to hold them together, a slight touch on the disk when turning the plate will at once cause the disk to jump; showing that small resistance creates a strong tendency for the two disks to separate. Since the device will operate as a perfect differential with one side stationary and the other free, it is obvious that it will still operate if we allow the under disk to turn too. Instead of standing the lower disk on a table, rest it on a greasy slab of glass. Then a sharp twist given to the center plate will cause the upper disk to move fast and will also cause the lower one to move slowly.

Fig. 3—The complete differential ready for assembly in the rear axle

Another Explanation

There is another way of explaining the action of differentiation. It is sometimes not clear, even with the differential in the hands, why it is that the two disks cannot revolve at the same speed without moving the plate. To explain this imagine a ball at the bottom of the lower groove *A* in the sketch. For this ball to get to the upper groove it has to run up to the end of lower *A* over the dividing piece and then down into upper *A*. Now it cannot do this unless two things happen together, one being that the other disk moves round so as to bring the deepest part of its groove over the dividing line at the time the ball crosses, and the other that the center plate also moves to allow the hole in which the ball lies to come round from the starting position to the finishing position of the travel of the ball.

The device is not only hard to describe in words and sketches, it is even hard to follow when handling the actual model, but it becomes clear after a little concentrated thought.

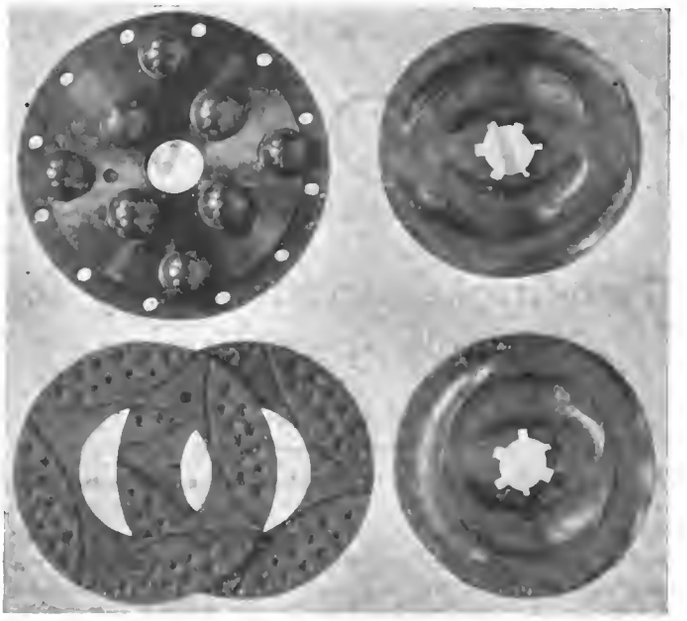

Fig. 2—All the internal parts of the differential as they appeared after the Purdue University test

Another thing which is not readily clear is why the differential will allow a car to pull out of a hole when one wheel only has a grip of the ground. To grasp this action suppose the wheel in the hole is spinning. Then all the power of the engine is going to this wheel. Since the expanding action of the differential causes internal friction the power is really divided between that absorbed by the spinning wheel and that used up in friction. But as soon as the other wheel moves the friction is relieved; therefore the friction exerts a torque upon the wheel having a grip on the ground and as the friction is large the torque is also considerable.

Self-Locking Action

This self-locking action by which the friction induced by the spreading of the disks arrests the spinning of the wheel without traction and converts its motion to torque on the stationary one may be explained in another way. Imagine each wheel with an independent brake. Obviously if a brake is applied to the spinning wheel it will be slowed down and the torque will be transmitted through the differential to the other wheel.

Of course there is no such brake in the differential under discussion, but the spreading of the disks into contact with the differential casing acts in the same way. Both disks are separated with equal force, but only that on the side of the spinning wheel has a braking effect because only on that side is there motion taking place between the disk and the casing relatively.

In practice the spreading action produces considerable forces and presses the disks against the containing case with heavy pressure. Their surface is large and provided with lubricating grooves as shown in the photographic illustration, and extensive tests made at Purdue University show that there is practically no measurable wear within a reasonable time. There is no backlash whatever when the gear is new, and none after a considerable period of use. Incidentally, the Purdue tests were made in a stout rear axle taken from a well known car and the forces applied were so great that the axle drive shafts were twisted till one of them broke off; which means the loads were greatly in excess of anything that could occur in practice.

At present the differentials are being manufactured on a small scale by the Miller Transmission Co., Karpen Building, Chicago. Arrangements are heing made for a very large output in the near future.

The FORVM

DO TWO-CYCLES OPERATE SUCCESSFULLY UNDER ALL LOAD AND SPEED CONDITIONS?—MORE VIEWS ON DIFFERENTIAL PROBLEM—RATTLING FENDERS

Two-Stroke Unsatisfactory for Variable Speed Engine

By C. C. Hinkley
Chief Engineer, Chalmers Motor Co.

I HAVE passed through considerable experimental work on two-stroke engines and in conclusion will say that they left a lot to be desired. For constant speeds and steady loads I believe they are very satisfactory especially for marine work; but, for variable speed engines of varying loads I have never been able to make them operate quite satisfactorily. I have never been able to make them two cycle under all conditions of load and speed. This is the one main drawback in connection with this motor which caused me to shelve the idea some time ago. It may be that my experimental work was not carried as far as it might have been at the time. However, I would very much hesitate to go into it again, knowing the difficulties that are to be encountered.

Resistance Differential Logical Solution

By John Squires
Vice-President and Secretary, Signal Motor Truck Co.

WE agree that it is obvious that from a constructional point of view it is desirable to eliminate the differential.

The writer can recall many situations in his past personal experiences in driving trucks, where the elimination of the differential would have been much of a handicap and consequently we cannot agree at the present moment that, from the operation point of view, this elimination would be desirable.

The resistance differential seems in our mind to be the logical solution of the matter at the present time, and we would prefer to see this more fully developed than that the differential be eliminated altogether.

Should Conduct Differential Experiments

By B. T. Birdsall
President, Kosmath Co., Inc.

IN regard to the elimination of the differential from trucks. This is a subject on which I have not given much thought but has been put forward by one axle maker. It would seem to me, however, that very thorough and exhaustive experiments should be conducted over a considerable period of time and in different localities before it would be safe to adopt so vital a change.

There is no question that if we could eliminate the differential it would be a good thing in many ways, but at the present time I would regard it as more or less of a dangerous proposition.

Fenders Rattle Too Much

By E. T. Crilley

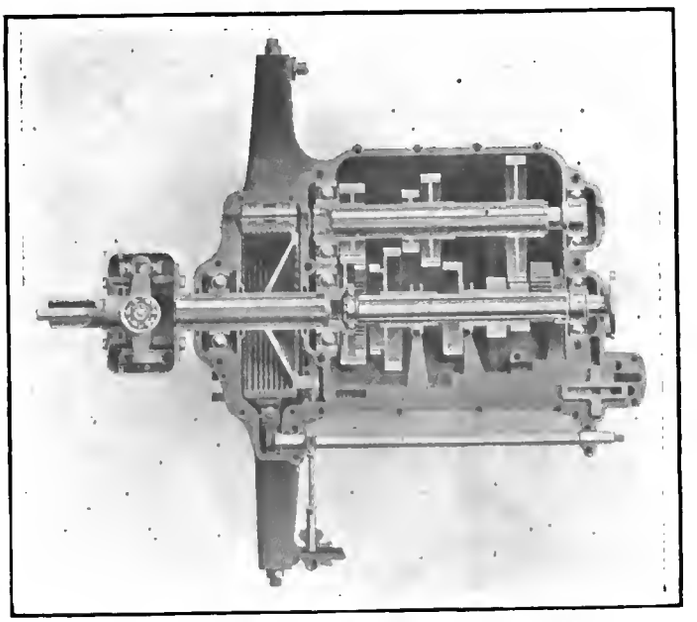
ONE of the most disagreeable things about the modern car, it seems to me, is likewise one of the most unnecessary. I refer to the rattling which frequently emanates from the fenders, especially after the car has been in use for some time. Of course, if the fenders are bent or broken in any way, some noise may be expected, but if our designers and builders would give the matter a little attention, I am sure that rigid mounting and elimination of loose or chafing edges would be avoided.

Universal Joints in 1905

By W. J. P. Moore

I WAS very much interested in your article on the above subject in THE AUTOMOBILE for May 25.

I am sending you an illustration of a ball bearing universal I used on the tail shaft immediately behind the gearbox in a car I built in 1905 and with which I had very satisfactory results; perhaps it will be of interest to you.



Ball bearing universal used on a car built in 1905

The History of the Pneumatic Tire—10

Further Activity in 1892—Michelin Tire Enters the Field—Introduction of Multiple Inner Tubes—Rapid Adoption of Pneumatic Tires for Bicycle Use

The History of the American Automobile Industry—37

By David Beecroft

CONTINUING the story of the tires invented or brought out in the year 1892, as begun in last week's installment of this series, there are a number of constructions which have not been mentioned. Some of these are briefly reviewed this week.

Sercombe-Bolte Construction

The Sercombe-Bolte tire of 1892 used a rim with its edges hooked outward instead of inward, and the tire had a flat metal wire in its edge of a diameter large enough to fit into these hooks. These metal wires were flexible enough to be forced into place, and when in place, prevented the tire edge from being pulled out of the groove, the main part of the strain being taken on that part of the rim which formed the point of the hook. This shape, however, caught dirt badly, was not easy to apply, tended to rim-cut and sometimes pinched the air tube.

The Michelin Tire

The Michelin tire, originated in France, was introduced in 1892 and used a rim flat on top but deeply grooved at its edges much like the rim of the Duryea cushion tire except larger. The tire casing had beads on its outside which were dropped into the bottoms of these grooves and endless rings placed in position over them, so the beads could not be pulled out. This rim, however, being of special shape and particularly objectionable because it filled with sand and mud, did not find favor and was quickly superseded by the Burris-Michelin, which used a casing having wires in its edges like the Dunlop but without the Dunlop rim. The rim used was flat bottomed and the wired edges were larger than the bottom of the rim so that a ring of square rubber or fabric could be placed in the corners of the rim and form a shelf for the edges of the tire casing. When this shelf ring was removed, the tire could be easily lifted over the rim edge and removed. It was one of the many attempts to evade the Dunlop wire-base construction.

Use of Multiple Tubes

In the same year, 1892, was introduced a tire having three air tubes or compartments any one of which could be used if another became punctured. The fault with this construction was that the point which punctured one was likely to puncture the next, unless it was found and removed, and often this required that the casing be examined on its inner surface. The multiple-tube idea has therefore not found favor. The same inventor, Dorr, developed a tire much like the Michelin but using a rim like the Burwell. Metal rings separate from the tire, instead of incorporated in their edges as in the Burwell, were used to hold the beads up into the outwardly turned rim hooks. This tire was found disadvantageous in much the same way as the Burwell and was not produced to any great extent.

The Pneumatic Gains

The indisputable advantage of the pneumatic tire forced the larger bicycle companies to supply it this year, in spite of the good business conservatism which prompted them to continue the all-rubber tires. The Pope Co., Morgan & Wright, and a number of others simply split the base of the hose pipe tire at one or two places and inserted an air tube, having closed ends which were abutted together, after which the openings were laced and the tire put in place. Canvas protectors were provided where the air tubes might be damaged by the lacing or the slits, and in some cases this canvas was extended completely around the air tube as on many modern air tubes. The Victor company, to avoid removing the tire and recementing it whenever it was necessary to remove the air tube, fitted its bicycles with rims having an opening through which the air tube could be reached and inserted or removed.

The Hose Pipe Type

It is well to distinguish the so-called hose pipe single tube tire in which the several layers are composed of ordinary canvas about an inner air tube and the hole vulcanized together, resulting in the identical structure found in a canvas-made hose pipe, whence the name. The only novel feature is the adjoining of the ends to form an angle and the insertion of a valve in the tube for the purpose of inflation.

The Rostrum

Steps in Installing an Air Starter

EDITOR THE AUTOMOBILE:—Please give a full explanation of the principle involved in the construction of an air starter? My four-cylinder engine has 4¼ by 5½ in. bore and stroke. I have a B Prest-O-Lite tank, a high pressure gage and safety valve.

Kindly describe and illustrate the parts necessary in this work.

Pittsburgh, Pa. J. G. H.

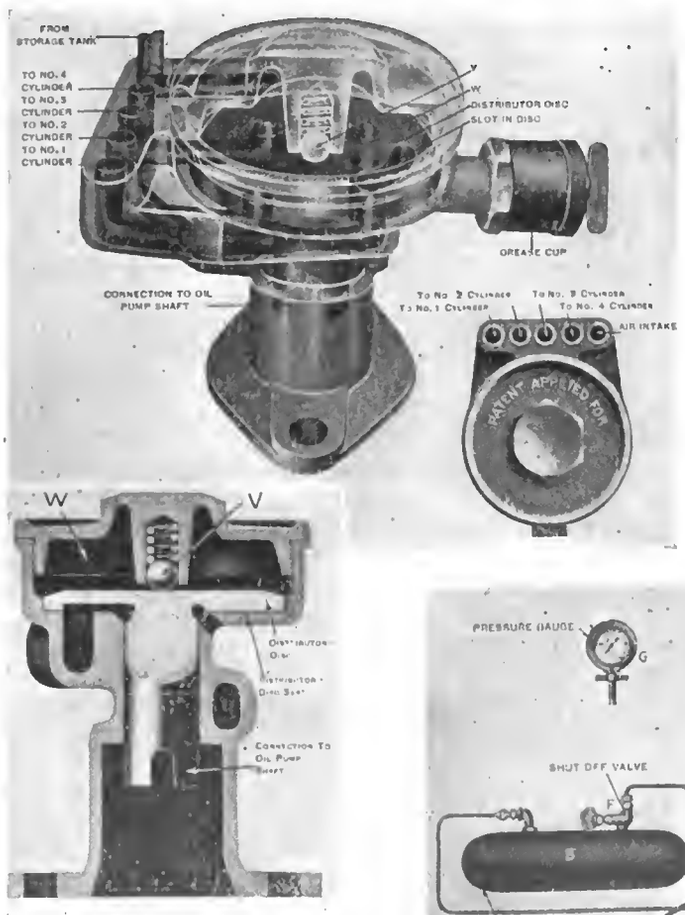
—The principle of the air starter is very simple as it is merely an arrangement for introducing compressed air instead of gas into the cylinder. The compressed air in expanding cranks the motor until it takes up its own cycle. It would not be practicable for you to attempt to make an air starter with the equipment you mention as one of the important parts of the system is a pump and check valve to maintain pressure in the tank. The amount of money which you would have to spend in installing the pump would be out of proportion to the return. Another necessary part of the system for an air starter is a distributer which directs the flow of the compressed air to the proper cylinder.

To give you an idea of the operation of a compressed air system a description of that used on the 1912 Chalmers 36 model 10 will be of interest. Fig. 2 gives a general layout of the air starting system together with the necessary piping and connections. As in all compressed air systems the operation of this device primarily consists of the introduction of charges of compressed air into the cylinders which are ready for the working stroke in their order of firing. The engine is operated with compressed air until regular explosions take place in the cylinders, after which the air supply is shut off and the motor takes up its regular operation on its own power.

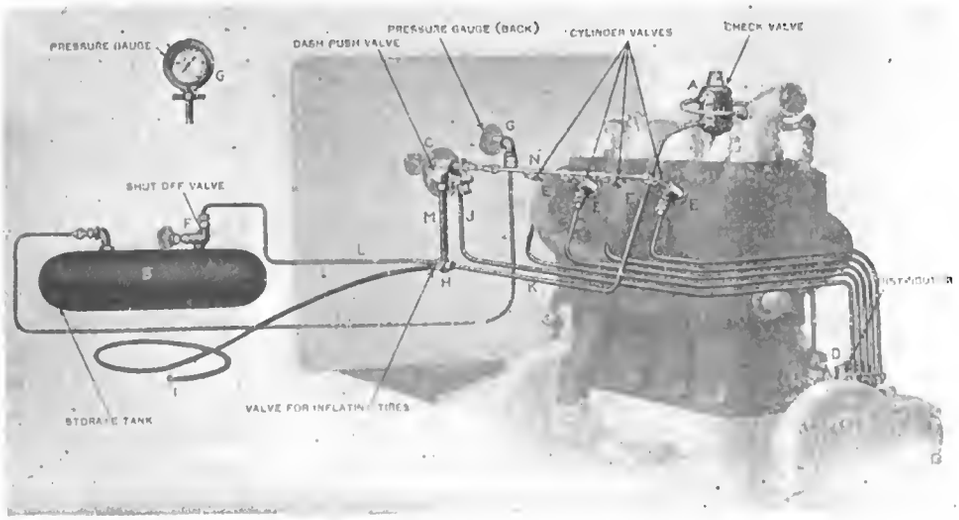
Referring to the illustrations, the parts of the Chalmers air starter are as follows: Check valve *A* for compressing air in storage tank *B*, a pipe *K* and *L* for carrying air from the check valve to the storage tank, a pipe *L* and *M* which carries air from the storage tank to the push valve *C* on the dash; a pipe *J* which carries compressed air from the push valve to the distributer *D*, four pipes through which air is carried from the distributer to the various cylinders; poppet valves *E*, one in each of the cylinders, by means of which compressed air from the distributer is admitted to the cylinder ready for the working stroke; a pressure gage *G* on the dash which keeps the operator informed of the amount of compressed air in the storage tank and a shut-off valve *F* which disconnects the starting mechanism from the storage tank.

Check Valve Is Important

The check valve is shown in Fig. 3. It is one of the most important parts of the system and on 1912 Chalmers consisted of a waterjacketed case inside of which is a check valve *O* held in place by a spiral spring *Q*. As the explosion occurs in No. 1 cylinder during the regular operation of the motor a part of the pressure of combustion passes through an



Left—Fig. 1—Details of distributer used in air starting system on 1912 Chalmers 36 model 10. The lower illustration is a vertical section



Right—Fig. 2—Layout of the air starting system used on the 1912 Chalmers model 10, showing piping

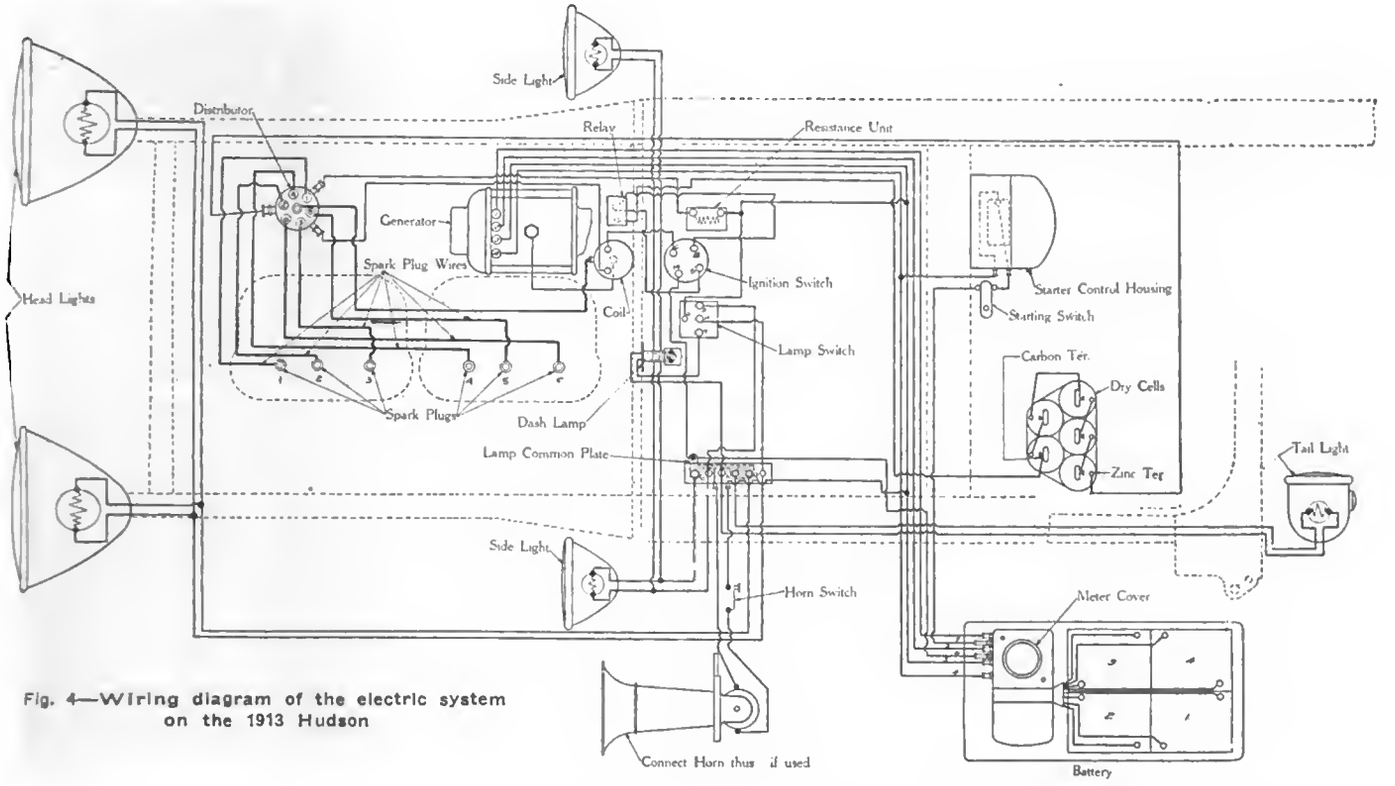


Fig. 4—Wiring diagram of the electric system on the 1913 Hudson

opening *R* lifting the valve *P* from its seat and allowing the escaping pressure to pass out through a pipe *S* into the storage tank. The storage tank on this car was lined with lead to prevent corrosion and was tested for a pressure of 600 lb.

The function of the distributer is to send charges of air into the proper cylinders ready for the working stroke in their order of firing. It is geared to the pump and magneto shaft and positively timed so that the charges of compressed air are fed to one cylinder at a time. As shown in Fig. 1, it consists merely of an air-tight case in which operates a small gear-driven disk. This disk is held in place by a steel spring and ball *V*. When air is released from the storage tank by the dash push valve it passes into the space *W* above the distributer disk. This pressure forces the disk down tightly upon its seat. As the disk revolves the air above it passes through the slot into one of the four holes beneath the disk and thence to the proper cylinder which is ready for the explosion stroke.

These are the main points of the system and as you will no doubt see it is quite a complicated installation and the equipment that you have will hardly be sufficient to allow you to arrange a starter.

Valve-Grinding Should Be Uniform

Editor THE AUTOMOBILE:—In grinding valves, should the valve be rotated in only one direction or should it be rotated back and forth without changing its position on the valve seat very materially?

Oyster Bay, N. Y. S. P. M.

—Since the object of the grinding is to make the valve seat tightly and smoothly on its seat around its entire circumference, the valve should be rotated in both directions with a uniform motion and from time to time during the process should be lifted and shifted on the seat so that all points will be ground evenly.

Wiring Diagram of 1913 Hudson

Editor THE AUTOMOBILE:—Kindly publish wiring diagram for attaching a dash ammeter to a 1913 Hudson model 54 so that same will indicate charge and discharge. I have made an attachment by cutting in the instrument in No. 1 wire from the motor generator, but this shows charge only, no discharge being indicated when motor is not running and all lights on.

Penn Yan, N. Y. A. T. B.

—It is not possible to connect an ammeter on this model so as to read charge and discharge. We note that you have inserted the instrument in the No. 1 wire from the motor generator, but this is not to be recommended. The best method is to remove the wire from the cut-out relay on top of the control switch and connect the ammeter between this wire and the terminal from which it was removed. A suitable length of wiring and metallic conduit would have to be provided to enable the ammeter to be located where desired. Wiring diagram of the electric system used in the 1913 Hudson appears in Fig. 4.

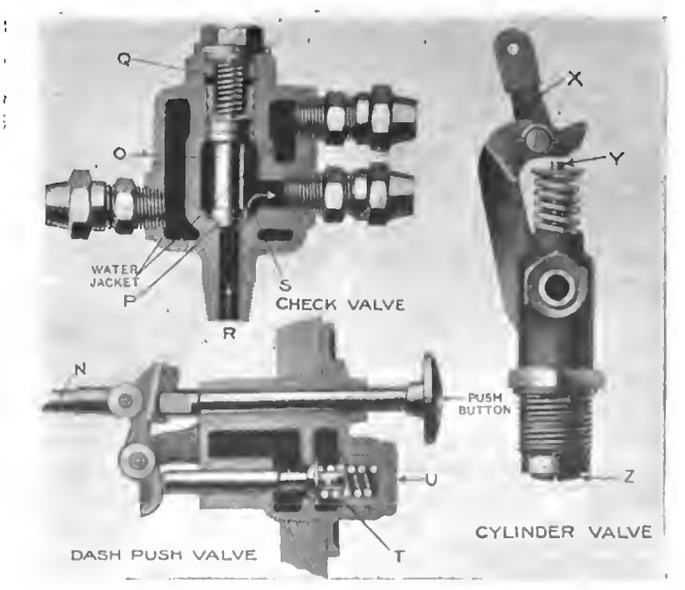

Fig. 3—Valves used in air starter on 1912 Chalmers

ACCESSORIES

J-A-Y Vacuum Gage

BY means of this vacuum gage a constant check may be kept on the gasoline as it is fed to the carbureter, showing just what is going on in the Stewart vacuum fuel feed tank. The gage is attached to a tap already existing in the tank, and registers every float operation of the tank, thereby telling at all times if the gasoline line is clear, if the carbureter is properly adjusted and if the car is making as many miles per gallon of gasoline as it should. In fact the device is a constant index to the gasoline feed system, showing when the supply in the tank should be renewed, and instantly indicates a development of any misadjustment or wasteful condition. It is easy to install, all that is necessary being the mounting of the gage on the cowlboard and attaching it to the fuel tank as indicated in the illustration. It sells for $5.—Webb Jay Corp., Karpen Bldg., Chicago, Ill.

J-A-Y vacuum gage which is a complete index to the Stewart fuel feed system

L-G Auto Lock

This lock is designed for cars having central control with a ball-and-socket type of shifting lever. The lever is locked in neutral position by a hinged ring which passes around the base of the lever. The ring is fastened by a padlock. It may be instantly applied to any car with this type of lever, it is said. Price $3.—Howard Automobile Co., San Francisco, Cal.

L-G auto lock designed for use on cars fitted with center control

Des Moines Spark Intensifier

The Des Moines spark intensifier operates on the spark-gap principle, its body being cylindrical with an insulated core carrying the conductors, an opening permitting the spark gap to be seen. The body of the intensifier has a little bracket at one end by which it is attached to the terminal of the spark plug and at the other end a binding screw for the high-tension lead. The width of the gap is adjustable. The makers claim that plugs which are badly sooted and fouled, or that have broken porcelains, will fire with the intensifier in the circuit when they would give no spark otherwise. The intensifiers sell for 75 cents apiece, or $3 for a set of four.—Des Moines Sales & Supply Co., Des Moines, Iowa.

Miller Safety Pilot

This device is intended for Fords and consists of a single coiled spring inclosed in a cylinder which is attached to the front axle at the middle by a bracket held by two clip bolts. An inner cylinder connected to the spring has a clamp projecting from an opening in the outer cylinder; this clamp attaches to the cross-rod of the steering gear. The spring normally holds the steering wheels in the straight-ahead position and tends to steady steering and minimize the strain on the hands of the driver in all positions of the wheels. Price, $5.—Safety Mfg. Co., Quincy, Ill.

Work bench for the equipment of private garages. It has steel legs and iron rails

Miller lock for Ford control levers

Protexall Dusters

These one-piece suits are an absolute protection against dirt. They are said to be cool and loose and are hooked over the regular clothes or even over an overcoat. The material is easily washed, is strong and durable and is furnished in several colors, both plain and striped. There is a combination loose and roll collar, a wide two-button adjustable cuff, buttoned side slits giving easy access to all pockets, continuous front opening. Sizes from 36 to 50 in. corresponding to coat sizes and may be had with extra long or sleeve length for tall men.—Protexall Co., Abingdon, Ill.

Garage Bench

This bench is for automobilists who have their own garages. It is a substantial construction, 4½ ft. long by 26 in. wide and 24 in. high. It is provided with a heavy cast steel vice and a drawer large enough to hold all ordinary tools. The legs are of steel and the cross rails malleable iron. Price, $14.50.—Motor Engineering Co., Cleveland, Ohio.

Bale's Puncture Plugger

This puncture plugger is injected into the tube with the result that when a puncture occurs, the hole is clogged by the liquid and air leakage is prevented. It is a fibrous compound largely composed of rubber and is in a semi-liquid state. As soon as it enters the punctured hole, it solidifies.—Bales Puncture Plugger Co., 301 North Illinois Street, Indianapolis, Ind.

Woods Everloc Patch

This patch is applied with cement, no heat being required and is said to permanently repair either blowouts or punctures. The material comes in sheets 6 by 18 in. and may be cut to any size. One sheet will repair 100 ordinary cuts or 250 nail punctures.—Price $1. A heavier patch for casing repairs sells for $1.50. —W. C. Wood Co., Minneapolis, Minn.

Luvium Metal Ford Pistons

Lightweight pistons of Luvium metal are now being made for Ford cars. Luvium metal has a specific gravity of 2.67 to 2.70. Though having the lightness of aluminum, it is said to have a tensile strength greater than cold-rolled steel, or twice the tensile strength of cast iron. It is made in hard and malleable forms and has proven satisfactory

Above—Control of Nokolyd electric signal
Below—Nokolyd signal mounted on car

for cylinders, connecting-rods, gears, crankcases, sprockets, magneto parts and other uses, the wearing qualities being considered superior to steel by the manufacturer. The new Ford pistons, in sets of four, sell at $21 per set. The company also makes other standard pistons. Inland piston rings made by the Inland Machine Works, St. Louis, Mo., are used. —Whitman Luvium Co., St. Louis, Mo.

Nokolyd Electric Signal

The Nokolyd is an electrically operated signal; the signal proper consists of a box mounted at the rear of the car which shows, in large letters, the words, Left, Right and Stop, controlled by a small lever on the steering wheel; the lever works over a dial lettered to correspond to the signals and having a neutral position. The letters are illuminated at night. Current may be obtained from the storage battery or from a special set of dry cells. The signal lists at $20.—Nokolyd Signal Co., New York City.

Adco Shock Absorber

An inclosed auxiliary spring replaces the rear spring shackle, the movable side members being corrugated and moving in corrugated slots which give increased wearing surface and prevent rattling of the operating parts. The construction practically makes the device dirt and waterproof. There are two springs—an outer coil, which is said to perform the initial work, and a stiffer inner spring which assists the outer one when the load is heavy. An elliptical adjusting nut at the top prevents the device from getting out of adjustment. There is a removable screw plug at the bottom so that grease may be put in. Price $20 per pair.—Auto Device Mfg. Co., 62 Mason Street, Milwaukee, Wis.

Brisk Blast Jack and Pump

These tire saving jacks are made with a simple rack and sector lever operated lift worked by the foot. A similar lifting jack designed particularly for Fords and other light cars has a height of 10½ in., 6½-in. lift and weighs 8½ lb. Price $3.

The company also makes a steel foot pump. It has two seamless steel cylinders, 1½ and ⅞ in. diameter, respectively, cold rolled steel plunger rods, hardwood handle and brass screw connection to fit any tire. Price $2.50. Another design with a single 1¼-in. cylinder sells for $2.—Brisk Blast Mfg. Co., 1515 North Twenty-fifth Street, St. Louis, Mo.

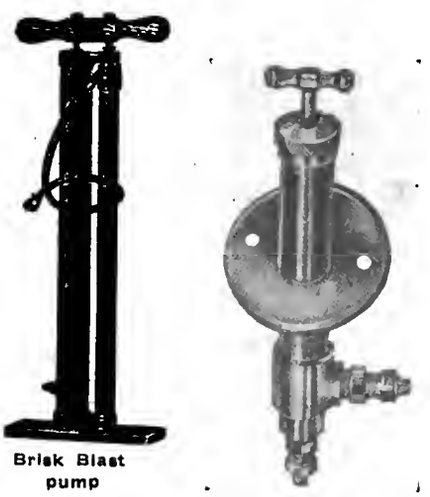
S-O-S Polishes

The No-Rub body polish is a liquid which will increase the brilliancy of the body surface but will not restore the finish once it has been destroyed by wear, abuse or neglect. It is applied with cheesecloth and after drying the body should be rubbed with a dry cloth. Price, pts., 57 cents; qts., $1.35.

The metal polish is a liquid which is applied with waste or cotton flannel, rubbed briskly and polished with a soft dry cloth or a chamois. Price, ½ pts., 25 cents; pts., 40 cents; qts., 75 cents.—S-O-S Mfg. Co., 167 South Stevens Street, Spokane, Wash.

Burnley Soldering Paste

The advantage of using a paste is that it spreads the solder evenly and quickly, it is said; the solder never tins before spreading. It is superior to a liquid flux because it does not run away from the point at which it is applied, and it cannot be spilled. A soldering stick is designed particularly for electrical work. It is rubbed on the heated joint and then the solder is applied in the usual way. It is wrapped in tin foil and will not corrode the wires or affect the insulation.—Burnley Battery & Mfg. Co., North East, Pa. Western Electric Co., distributor.



Brisk Blast pump

Ideal Primer and Cup

The Ideal primer is nothing more than a small gasoline pump installed on the dash or cowl. Its suction end is connected to the fuel tank and its discharge to the manifold, so that the motor may be primed by simply operating the handle. The stem of the handle is threaded so that the pump valve may be closed tightly by turning it a few times; thus leakage is prevented. It sells for $3.

The most important feature of the Ideal priming cup is that the valve itself is of the needle type and is proof against leakage, even when used on high-compression motors. The turning knob is a fiber disk, so that there is no danger of burning the fingers. Price, nickel finish, 50 cents; brass, 40 cents.—Ideal Brass Works, Indianapolis, Ind.

Delker Trailer

The Delker two-wheeled trailer has a capacity of 1000 lb. and is made in a single model. The body is 44 by 72 in., with 8-in. panels and hardwood sills braced and ironed, and the flareboards are well braced; there is an end gate and rings at front and back so loads can be tied in. Wheels are Sarvens, riveted rims and 34 by 1¼ solid rubber tires. The axle is of 1¼-in. steel and the wheels run on Timken roller bearings. Springs are 1½ in. wide with six leaves. Finish, black with striping. Shipping weight, about 375 lb.—George Delker Co., Henderson, Ky.

Dazzle Dimmer

A diminutive roller-shade is clipped to the top of the windshield, and from it a little curtain of tinted transparent material is pulled when required. It can be put up or down at an instant's notice, and can be slipped along the windshield to any desired place. The maker states that the curtain is so tinted that it is possible to see how many persons there are in an approaching car in the face of the headlights. Price, $1.50.—The Dazzle Dimmer Co., Springfield, Mass.

Materials Steady

AFTER the period at the end of last year when steel and other raw material prices seemed likely to soar to unheard-of prices, it is good to be able to record the fact that the prospects from the automobile industry's viewpoint are now brightening again. In December and January the situation looked so gloomy that actual panic threatened; now, though prices are still way up, the fear that no supplies whatever may be forthcoming seems over.

The effect of the foreign demand has been to boost American production of everything needed in Europe. In certain respects the European demand is slackening, the machine tool industry in particular is well within sight of the end of phenomenal foreign buying, while the demand for aluminum is lessening by regular, if slow, degrees. It will be a long while yet before our manufacturers can enjoy before war prices, but there is less fear now that production will be curtailed by inability to get enough steel.

Few New Multis

AS yet it is, of course, too early to make any accurate analysis of the specifications of the 1917 cars, but from what has been published and what is known to be the plan of many other manufacturers, it is obvious that there are not going to be many more eights and twelves. The four-cylinder machine is holding its own along the line; there have been several new sixes, and those formerly making sixes will mostly adhere to that type.

This tends somewhat to confirm the view which THE AUTOMOBILE has held from the very beginning of the V engine, namely, that there is ample room for all types, from the four, which is the lowest cylindricity that will provide smooth operation, to the twelve, which gives the theoretical maximum of smoothness. Having regard to the performance of the 300-cu. in. Packard aviation engine, it is rather surprising that we have heard nothing yet of a small, high grade twelve as a stock model; still there is ample time yet and the anticipation that one or two such will appear holds good.

Tonneau Windshields

ONE big change that has taken place in American automobiles in the last 2 years has been in their average comfort. While much remains to be done, much has been accomplished already, and it is thus fitting to speculate regarding the next step. That the heater, connected with the exhaust, is soon going to be expected as a stock accessory on medium and high priced cars is assured, and having thus cared for the lower extremities of the tonneau passengers the tonneau windshield appears to be the next logical step.

Of the special designs which can be bought for attachment to any car, some are fairly neat and some are very clumsy, but not one of them is as light or as simple as it might be if it were designed for one single body and if that body were designed to accommodate it. The center cowl now so popular should make the fitting of a tonneau shield a far simpler matter than it used to be with the old style of front seat back. It should provide a place for stowing the shield when not in use and points for attachment of the supports, which would not call for elaborate supporting brackets. Once tried, the tonneau shield becomes as much a necessity as the shield in front. It will be a wonderful selling argument for the first manufacturer who takes it up.

British Tax Lifted

THE proposed enormous increases in the annual license dues on automobiles in England have been abandoned as a result of the agitation of the trade press and of the various motoring organizations. The British taxes are based on cylinder bore, and would have raised the license on a Ford to over $90 a year. Instead of the increases in annual dues an extra tax for war time only has been placed on gasoline, this being 12 cents a gallon. This is in addition to the 6 cents a gallon which is the peacetime tax.

The change in the Government's plan is an advantage to the users of American cars, as these are mostly of large bore compared with the European types; but the American organizations should observe the situation with satisfaction, because it is proof of the power of motoring associations backed by a strong trade press.

$170,000,000 for Good Roads

President Signs Bill for $85,000,000—States to Pay Same Amount

WASHINGTON, D. C., July 11—*Special Telegram* — President Wilson to-day signed the good roads bill recently passed by Congress, authorizing the expenditure of $85,000,000 in 5 years by the Federal Government. The signing of the bill by the President marked the final act before the beginning of active co-operation between the national Government and the States in highway improvements, on a country-wide program.

The condition attached to the expenditure of the government appropriation is that the States shall expend an amount similar to that appropriated to them for the indicated improvement. The signing was witnessed by members of the Senate and House and representatives of various farmers' organizations. Officials of the American Automobile Assn. and the Assn. of State Highway Officials also were present.

The bill provides that in addition to the money to be spent in co-operation with the States $10,000,000 shall be provided for roads in Federal forest reserves, to be spent at the rate of $1,000,000 a year for 10 years.

The co-operative plan which became effective to-day is said to have sprung from the combined energies of the American Assn. of State Highway Officials and the American Automobile Assn.

Twenty-one Firms Bid for Army Light-Truck Orders

NEW YORK CITY, July 12—The Quartermaster's Department has opened bids on from one to forty ¾-ton trucks, and in response to its call, twenty-one firms have replied with bids ranging variously.

A few of the lowest bidders follow:

The Bessemer Motor Truck Co. offered to supply from one to forty ¾-ton trucks, chassis with body complete, for $995 f.o.b. Grove City, Pa. Five days after the award of order this concern promised to start shipment, and complete it within 30 days.

The Selden Motor Truck Sales Co. offered chassis model G complete, $996 each; Stewart Motor Corp., at New York, 1500-lb. chassis, $596 each; chassis with express body, $640; chassis with panel body, $676; delivery to commence on receipt of order and to be completed in 20 days.

T. B. Jeffery Co., 1 to 40 Jeffery rapid-service trucks, with express body and top cover, in lots of one to twenty-five, $850.60; in lots of twenty-five to fifty, $840.75. Delivery, three complete units every working day, to start one week after award.

General Motor Truck Co., regular model No. 15 chassis, complete with flare board body, $1,096; extra for electric self-starter, $125; extra for generator and electric lights, $80; extra for canopy tops, $40. Delivery a week after award, four a day thereafter from Pontiac, Mich.

Reo Motor Car Co., model M truck, six-cylinder, at $1,000 each. Delivery, six per working day.

Studebaker Corp., forty 1-ton, with express body, $1,200, or forty 1-ton, with staple body, $1,250, less 15 per cent, or $1,020 net. Delivery 2 weeks after award, and four a day thereafter.

Republic Motor Truck Co., ¾-ton truck, $897, including express body, f.o.b. Alma, Mich. Order completed in 5 days, ten a day.

Denby Motor Truck Co., one to forty trucks, open express, flare board bodies, furnished with solid or pneumatic tires, $990 f.o.b. Detroit; with Allis-Chalmers electrical system, $1,075. Delivery with electric system, ten in 24 hr.; fifteen every additional 24 hr.

Day-Elder Motor Truck Co., Open express body, $175; delivery starting 10 weeks after award, with two to four a week thereafter; chassis complete, $895; electric self-starter and lights, $85 extra.

—

Only Three Bids for Shop Trucks

NEW YORK CITY, July 10—Only three truck companies put in bids at the Depot Quartermaster's Department last Saturday for proposals for furnishing the United States army with from one to fifty motor truck machine shops.

The Hurlburt Motor Truck Co. stated that it could supply from one to twenty-five trucks for $7,000 each. Shipment could begin 90 days after award of order.

The J. G. Brill Co. offered to supply one to fifty machine shop truck bodies at $429 per body. The White Company put in a bid for the one to fifty complete 3-ton truck machine shops, less tools and machinery, for $3,445, delivery to start 5 weeks after placing of order, with five a week thereafter.

—

Marmon Adds Closed-Body Types

INDIANAPOLIS, IND., July 11—The Nordyke & Marmon Co. will increase its output of closed cars considerably this fall. The bodies will be built by such firms as Holbrook & Co., New York; New Haven Carriage Co.; Kimball & Co., Chicago; and the E. J. Johnson Co. of Pittsburgh.

The light-weight characteristics of the chassis will be maintained in these bodies and it is stated that Marmon closed cars will turn the scales at from 3800 lb. to 4000 lb. The floorboards are lower than usual, on account of the special frame construction and the total height to the top of the roof from the ground will be 81 in., fifty-four of these being from the floor to the inside of the roof. Extra wide rear doors will be fitted and all the windows will slide instead of folding, giving any degree of opening desired.

The standard line includes limousine, landaulet, town car and convertible sedan. Deliveries will be commenced in August or September.

—

Milburn Raises Price $100

TOLEDO, OHIO, July 10—The Milburn Wagon Co., manufacturers of the Milburn Light Electric, like the majority of other automobile manufacturers, has been compelled, owing to the increased cost of labor and materials, to advance the selling price of one of its products. Announcement is made that the model 22 brougham, formerly selling at $1,585, will be listed at $1,685, taking effect July 15.

Sales Congress Opens

President Wilson in Address to 3000 Indorses Better Business and Salesmanship

DETROIT, MICH., July 10—*Special Telegram*—President Woodrow Wilson to-day gave his indorsement to "the betterment of business through the betterment of salesmanship." When he addressed the World's Salesmanship Congress in the Arcadia Auditorium he was enthusiastically received by the audience of 3000, to whom he drew close in his brief but explicit remarks.

He pointed out the future that lies in store for the United States and attributed success in selling relations and in business to a close understanding between the two parties to the transaction. His opinion of his audience and of American business was indicated when he said:

"I have always believed, and I think you have always believed, that there is more business genius in the United States than anywhere else in the world."

—

King 8 Makes Providence-Detroit Run on High Gear

DETROIT, MICH., July 12—*Special Telegram*—At 7 o'clock this morning a King eight model E stock car arrived here from Providence, R. I., having made the entire distance of 837 miles on high gear. Both the gear shifter and differential housing are sealed and the car has the standard ratio of 4.64 to 1. The driver was A. F. Justin of the Longley Motor Sales Co., of Providence. Passengers were H. G. Belcher of the *Providence Tribune*, H. H. Weeks, R. J. MacKenzie and C. F. Stanley. The route covered was from Providence to Albany, through the Berkshires, Albany to Buffalo, Buffalo to Niagara, through Canada by way of Hamilton, London and Windsor. Roads through Canada were found very bad. The biggest day's travel was on Tuesday, when 349 miles were covered.

—

King Used Champion Plugs

NEW YORK CITY, July 11—The King eight-cylinder car, which covered 10,850 miles in 2 weeks during the latter part of June without stopping its engine used Champion spark plugs. The object of the test was to demonstrate the stability of the King engine and its equipment.

—

Perfection Heater on Cole

CLEVELAND, OHIO, July 7—The 1917 Cole-Springfield model will be equipped with the Perfection heater, manufactured by the Perfection-Spring Service Co., this city.

Gillette To Build Sleeve Engine

May Take Over Amplex Plant To Build Wilmo Engine and Accessories

SOUTH BEND, IND., July 8—It is unofficially stated that William Gillette, the millionaire razor king, will take over the Amplex Auto & Machine Works, located at Mishawaka. The new company will be known as the Gillette Motor Co., and will manufacture the Wilmo rotating sleeve motor patented by M. L. Williams, formerly of South Bend, now of Chicago. Mr. Williams will be interested in the plant and will move to Mishawaka, where he has purchased a residence. The company will also manufacture automobile accessories. Ray Austin of Mishawaka will be the chief engineer of the company and C. E. Erickson of Chicago will be the general manager. The Amplex was built a number of years ago and eventually was purchased by Hovey & Starrett of Detroit, later going into the hands of a receiver. It was purchased by Rudolph Kamm, one of the original stockholders, and has been operated as a job machine plant.

Smith Resigns from Chalmers to Join Harry Newman

MILWAUKEE, WIS., July 8—F. H. Smith, assistant sales manager of the Chalmers Motor Co., Detroit, Mich., has resigned to become associated with the Harry Newman organization, Milwaukee, Chicago, Springfield, Ill., as manager of the northwest division. The northwest division will continue to be handled from the Milwaukee store at 700-706 Grand Avenue.

Guy Resigns from Advance-Rumely

SOUTH BEND, IND., July 8—J. H. Guy, vice-president and treasurer of the Advance-Rumely Co., Laporte, who has been with that organization since the spring of 1913, has resigned from the concern and in a short time will return to New York. When Mr. Guy went with the Rumely company it was his intention to remain but a short time, but when the troubled conditions of 1913 came he stayed on to help straighten out the company's affairs.

Higrade Motors May Locate Plant in Grand Rapids

GRAND RAPIDS, MICH., July 8—Business men in this city have pledged $50,000 for the erection of a plant for the Higrade Motors Co., which will build commercial vehicles. As proposed by J. E. Pratt, W. J. Loomis and L. W. Coppock of the company, $100,000 cash working capital will be put up by the Higrade company, providing the business men of Grand Rapids will buy the site of 20 acres selected by Pratt and his associates, and will build the plant on 5 acres of it. The plant will be leased at 7 per cent of the cost, plus 3 per cent for depreciation of buildings.

The site will cost between $12,000 and $15,000 and the building in the neighborhood of $35,000. The company was incorporated last week with a capital of $250,000. J. E. Pratt heads the organization. A brief description of the truck appeared in THE AUTOMOBILE for June 29.

Watkin Wright Roller Sales Manager

PHILADELPHIA, PA., July 7—L. W. Watkin, Jr., who for the past 9 years has been connected with the sales and engineering department of the Standard Roller Bearing Co., has recently become sales manager of the Wright Roller Bearing Co., this city, and Spring City, where its factory is located. This company manufactures taper roller bearings for the automobile trade.

Benford Need Not Change Form of Plugs

NEW YORK CITY, July 11—The decision of Judge Hand, recently rendered in the case of the Champion Spark Plug Co., insures to the Benford Mfg. Co. the right to make and sell its Reliable type ½-in. plug exactly in the same form and proportions as before the initiation of the suit, the only stipulation being that none of these plugs shall have the black finish or the brand in red.

A New Marathon Tire

CUYAHOGA FALLS, OHIO, July 7—The Marathon Tire & Rubber Co., this city, has brought out a new ribbed tread tire, named the Runner. There will be no change in price with the usual 5000-mile guarantee.

The tread of the new tire has three parallel ridges of rubber surrounding two hollows. The design protects against side slip. The new tire is furnished with white tread and fabric body or with black tread and whipcord carcass.

W. J. Forbes, Accessory Man, Dies

BOSTON, MASS., July 8—W. J. Forbes, one of the pioneer accessory men in New England, and who built up a big business making bodies of various kinds for Ford cars, died here this week following an illness of some weeks. He entered the accessory field 17 years ago.

Brown Leaves Premier

INDIANAPOLIS, IND., July 6—H. M. Brown is resigning as stock superintendent of the Premier Motor Corp. to accept a position as production manager for a concern in northern Indiana.

Saxon Six Averages 34⅔ M. P. G.

206 in Non-Stop Run—Average 23.5 M.P.G.—175 M.P.Qt. of Oil

DETROIT, MICH., July 10—Results of the Saxon Motor Car Co.'s 300-mile non-stop run, conducted in all parts of the country by the Saxon dealers on July 1, have indicated that the Frye Motor Car Co., St. Louis, Mo., attained the greatest mileage ger gallon, and hence this dealer gets the silver loving cup that was posted as the award for the winner. The Saxon six driven in the test by this concern averaged 34 2-3 m.p.g.

In the non-stop run, 206 Saxon sixes participated, traveling a total distance of 61,800 miles, and having a grand average of 23.5 m.p.g. of gasoline and 175 miles to the quart of oil.

A newspaper man acted as observer in each case, and while the tests were not official, the results obtained are accurate in all cases so far as known. Some of the contestants encountered bad roads and hilly country, while rain interfered in other localities.

Some of the results obtained are as follows:

Place	Dealer	Average mileage per gallon
St. Louis, Mo.	Frye Motor Car Co.	34 2/3
Rochester, N. Y.	Wm. Knipper	20.1
Stockton, Cal.	Parnell & Letourneau	28
Portland, Ohio.	Saxon Motor Sales Co.	27 3/11
Toronto, Ont.	Saxon Sales Co.	24
Minneapolis, Minn.	Northwestern Automobile Co.	33.96
Geneva, N. Y.	C. J. Allen	32.15
Los Angeles, Cal.	Saxon Motor Sales Co.	27.57
Alva, Okla.	T. W. Bickel	26.67
Lincoln, Neb.	F. B. Packwood	23
Memphis, Tenn.	Memphis Motor Car Co.	21.1
Hazelton, Pa.	G. S. Danke	21.3
New Castle, Ind.	E. R. Skinner	24
Grand Rapids, Mich.	Grand Rapids Saxon Co.	27.5
Buffalo, N. Y.	Loveland Company	25.7
Cincinnati, Ohio.	Hellman Motor Car Co.	26.1
Wilkesbarre, Pa.	Sterling Motor Car Co.	18.6
Chattanooga, Tenn.	Jones Automobile Co.	19.5
Kansas City, Mo.	Bond Motor Co.	26.69
Galesburg, Ill.	Seacord & Sons	21.9
Providence, R. I.	Saxon Motor Vehicle Co.	24.6

25,399 Saxons Shipped in Year

DETROIT, MICH., July 10—The Saxon Motor Car Corp., this city, shipped in the fiscal year ended June 30, 25,399 cars compared with 12,099 in the previous year, an increase of 110 per cent.

In no month of the last fiscal year did shipments fall behind the corresponding month of the previous fiscal year. In June shipments were 3122 cars compared with 2710 in June, 1915. A new record for monthly shipments was established in April, 1916, when 3405 cars were shipped. Net earnings are estimated at $1,250,000.

England To Control Gasoline

Now Taking Automobile Census to Enable Authorities to Decide on Future Action

LONDON, ENGLAND, June 15—The long-threatened Government control of all gasoline supplies is now about to become a fact. This week an order was issued for the taking of an automobile census throughout England, every owner of a car being under an obligation to secure a form from a post office and declare to what use his car is being put, how much gasoline he has been using, and how much he considers he will use in the future. It is understood that the information obtained from this census will enable the authorities to decide on their future line of conduct.

Just before the order for this census was sent out, the gasoline committee of the Board of Trade had sent out an "Order of Priority for the Distribution of Motor Spirit." Excluding the army, the navy and the postal department, which are supplied first in any case, this order divides motor users into three classes. Class A includes the transportation of war material, fire brigades, ambulances, various government officials, police, and veterinary surgeons. Class B includes most of the commercial users of gasoline, as for agricultural purposes, the distribution of goods, taxicabs, fishing and cargo boats, motor omnibuses, railroad companies, stationary engines, and aeroplane schools. Finally in class C are grouped all other users, among them being owners of pleasure motor buses, taxicabs hired from garages, boats running for pleasure, hotels, etc.

Classes A and B First

The requirements of Classes A and B are to be given priority. Whatever supplies remain can be sold to those coming in Class C. The gasoline committee, which consists of six members of the gasoline industry working in conjunction with the government, has sent a circular letter to all garage proprietors and gasoline dealers, informing them that this priority scheme must be adhered to, and threatening more drastic measures if cooperation is not secured. At the same time the public has been reminded that the law forbids the storing of more than 60 gallons of gasoline in any one storehouse, which must be 20 feet from any other building.

If there really is a shortage of gasoline the priority scheme of distribution cannot be objected to in the main. The only unsatisfactory detail is that in Class C —comprising those people to be served last—there is no discrimination between the people who use cars merely for pleasure touring and owners who require an automobile in connection with their domestic or commercial life. There is a strong suspicion, however, that these attempted motoring restrictions are prompted more by anti-motoring feeling than by any actual or threatened shortage of gasoline. For months all England has been placarded with huge posters asking that cars should not be used for pleasure purposes. Undoubtedly much of this money has been wasted, for posters with letters four feet high have been placed in poor neighborhoods where not a single automobile owner could be found. Motorists could have been reached in a much more direct and economical manner.

—

$1,000,000 Additions for Moline Plow Tractor Dept.

MOLINE, ILL., July 5—The Moline Plow Co. has decided to enlarge its plant in order to take care of its tractor department. Plans are under way by architects for the construction of buildings which will cost $1,000,000 and give employment to 1500 men. The company proposes to erect a machine shop, 100 by 765 ft.; foundry, 180 by 360; pattern vault, 64 by 230; core room, 60 by 122; mill room, 80 by 200; and cupola room, 60 by 60. The buildings to be erected, are to be devoted exclusively to the construction of farm tractors. The demand has become so great that the present facilities are entirely inadequate.

—

British Tax Gasoline 18 Cents per Gallon

LONDON, June 25—England has abandoned the threatened double and treble taxes on automobiles in favor of a special war tax of 12 cents per gallon on gasoline. The amount will be reduced to 6 cents per gallon in the case of doctors and veterinary surgeons. The main features of the new law are the use of gasoline permits, supplied monthly for a specified amount of fuel, and the payment of the tax at the rate of 12 cents per gallon at the time of taking out the permit.

The recent automobile census has paved the way for this scheme. Owners of cars will have to apply to a central authority for a permit to purchase gasoline, and obviously this authority will have power to refuse the permit or to restrict the amount to be purchased. The tax will be paid at the time of taking out the permit, and gasoline can only be obtained on presentation of this document to the dealer. These permits will only be issued for periods of 1 month. It is officially stated that the gasoline tax will only be in force for the length of the war. The revenue obtained from this source is expected to be $4,810,000 per annum.

200,000 May Watch Tractor Tests

Dallas Demonstrations July 18-21 Promise to Be Big Success

DALLAS, TEX., July 8—That the interest in the first national tractor show to be held at Dallas July 18 to 21 is even greater than the committee in charge of arrangements had expected is indicated by the hundreds of queries that are received daily and by reservations that are being made at local hotels. Indications are, and plans to that end are being made, that 200,000 people will witness the tractor demonstrations. These demonstrations will be given daily, each afternoon, on the 1000-acre Caruth farm 5 miles north of Dallas.

Already there have been 123 tractors registered for the demonstration and before the week's end it is expected numerous others will be registered. Entries already made are as follows:

Avery Tractor Co., Peoria, Ill., twelve tractors; Texas Harvester Co., Dallas, Tex., ten; J. I. Case Threshing Machine Co., Racine, Wis., ten; Emerson Brantingham Plow Co., Rockford, Ill., ten; Advance Rumely Thresher Co., La Porte, Ind., nine; Twin City Tractor Co., Minneapolis, Minn., eight; Sattley Bull Tractor Co., Dallas, Tex., six; Rock Island Plow Co., Rock Island, Ill., four; B. F. Avery & Sons, Louisville, Ky., four; Moline Plow Co., Moline, Ill. four; Ford Tractor Sales Co., Dallas, Tex., four; C. O. D. Tractor Co., Minneapolis, Minn., four; Denning Tractor Co., Cedar Rapids, Iowa, four; Joliet Oil Tractor Co., Joliet, Ill., three; Peoria Tractor Co., Peoria, Ill., three; Waterloo Gas Engine Co., Waterloo, Iowa, three; Parrett Tractor Co., Chicago, Ill., three; Electric Wheel Co., Quincy, Ill., three; Interstate Engine & Tractor Co., Waterloo, Iowa, three; Waite Tractor Sales Co., Chicago, Ill., three; Simplex Tractor Co., Minneapolis, Minn., three; McIntyre Mfg. Co., Columbus, Ohio, three; Allis-Chalmers Mfg. Co., Milwaukee, Wis., two; Standard Detroit Tractor Co., Detroit, Mich., two tractors.

On Tuesday, July 18, the forenoon will be used for private demonstration, the public demonstrations being made from 1 to 3 in the afternoon. In addition to plowing, the demonstrations will cover such other operations as disking, seeding, manure spreading and operating various farm machinery. Dynamometer tests will be made with a 14-in. plow and the actual pounds drawbar pull ascertained. Exhibitors may burn any fuel they like, but must obtain it from a source designated by the management.

In addition to the tractor exhibition there will also be an extensive exhibition of accessories such as may be used with and on farm tractors. Among the accessories exhibitors who will have space are:

Sumpter Electrical Co., Chicago.
Eisemann Magneto Co., Brooklyn, N. Y.
Diamond Chain Co., Indianapolis.
Kingston Co., Kokomo, Ind.
Bennett Carburetor Co., Minneapolis.
Waukesha Motor Co., Waukesha.
Beaver Motor Co., Milwaukee.
McQuay-Norris Co., St. Louis.
V. Ray Spark Plug Co., Marshalltown, Iowa.

Hyatt Roller Bearing Co., Detroit.
Piston Ring Co., Muskegon, Mich.
Reflex Ignition Co., Cleveland.
Continental Motor Co., Detroit.
Champion Spark Plug Co., Toledo.
K. W. Ignition Co., Cleveland.
Ever-Tight Ring Co., St. Louis.
Burd Ring Co., Rockford, Ill.
Perfex Radiator Co., Racine, Wis.
Kerosene Burning Carburetor Co., Detroit.
Atwater Kent Mfg. Wks., Philadelphia.
Bosch Magneto Co., New York.
New Departure Ball Bearing Co., Bristol, Conn.
Manhattan Electrical Co., New York.
Platt & Washburn Refining Co., New York.
Diamond Chain Co., Indianapolis.
Harroun Carburetor Co., Indianapolis.

To Collect and Publish Gasoline Statistics to Reduce Prices

WASHINGTON, D. C., July 10—Another step in the fight being waged to find out the reasons for the rapid rise in the price of gasoline was taken today when the committee on mines of the House of Representatives reported favorably the Carter bill providing for the collection of information upon which Congress may base legislation to meet the constant advance in the price of gasoline. The bill, which was introduced some weeks ago by Representative Carter, of Oklahoma, authorizes the Secretary of the Interior to collect and publish all possible statistics and data relating to the production and marketing of petroleum products. These statistics and data shall embrace specifically the number of wells drilled, total amount of products and any other information of benefit and value to oil production, all of which shall be for the general information and use of the public. The bill carries an appropriation of $20,000 to defray the expenses of the investigation during the present fiscal year.

It is expected that final report of the Federal Trade Commission on its investigation into the gasoline and oil situation in the United States probably will be completed within 2 weeks.

Chevrolet to Add in N. Y.

NEW YORK CITY, July 10—The Chevrolet Motor Co., this city, has let a contract for the erection of two additions to its automobile plant. They will be five stories, 200 by 200 ft., and three stories, 100 by 150 ft. respectively.

Mitchell Refinancing Completed

Capital Consists of 125,000 Shares of No Par Value—Stock at $67

NEW YORK CITY, July 11—The Mitchell Motors Co., Inc., has been formed and will acquire and operate the business of the Mitchell-Lewis Motor Co., Racine, Wis. The new company has a capital of 125,000 shares, no par value, and the issue has been syndicated by Ladenburg, Thalmann & Co. and A. G. Becker & Co. of Chicago. The offering price of the stock is $67 a share.

The Mitchell-Lewis Motor Co. was founded in 1903 and the output has grown from eighty-two cars in 1904 to 6186 in 1915. For the present fiscal year to end Oct. 13, the output will be upward of 10,000 cars.

On this output and results obtained thus far, earnings for the present fiscal year are estimated at $1,400,000, or over $11 per share. During the 10 months ended Oct. 31, 1915, net profits of the company were $815,756 or $6.50 per share.

An audit by Price, Waterhouse & Co., shows total net tangible assets of $4,500,000, equivalent to $36 per share. Net current assets are over $2,000,000, of which $926,672 is cash.

Mitchell cars are being produced at present at the rate of 15,000 per annum and the present plants have an annual capacity of 18,000 cars.

The company will acquire the plant of the Mitchell Wagon Co., in which the bodies for its cars are now built. This will make the company one of the few which build the bodies for their output. It is stated that the saving through the acquisition of the body plant in the next fiscal year will amount to about $200,000.

Maxwell to Purchase First Preferred

NEW YORK CITY, July 12—At the monthly meeting of directors of the Maxwell Motor Co. only routine business was transacted.

Under the provision of the sinking fund of Maxwell first preferred stock, the company will pay to the Central Trust Co. as agent, about $140,000 to be applied to the purchase of Maxwell first preferred after advertising for offers. The sinking fund may purchase up to, but not above, par. At present prices for the stock the sinking fund would be able to buy over 1600 shares.

Tireoid Directors Announced

CHICAGO, ILL., July 12—The Tireoid Co., this city, manufacturer of a puncture sealer under that name, has announced its board of directors as follows: A. W. Armour, vice-president of Armour & Co., this city; M. J. Insull, president of the Middle West Utilities Co., this city; N. N. Lampert, president of the Chalmers Motor Co. of Illinois; Lafayette Markle, president of the L. Markle Co., Studebaker distributor in Chicago; H. H. Merrick, general manager of credits of Armour & Co., Chicago; H. E. Otte, vice-president of the National City Bank, Chicago; W. T. Perkins, assistant cashier of the National City Bank, Chicago; C. W. Price, president of the Overland Motor Co., Chicago; F. E. Price, vice-president of the Overland Motor Co.; W. L. Rohrer, president of the Tireoid Co.; and Maj. R. E. Wood, General Asphalt Co., Philadelphia.

Tireoid is a semi-liquid compound, mostly mineral. It was invented a year ago by R. T. Garvin, a chemist. The company guarantees for a period of 6 months from date of purchase that the compound will seal all punctures of a diameter not to exceed that made by a nail.

Aluminum Lower

NEW YORK CITY, July 11—Activities in the automobile materials markets last week were on by a drop in aluminum and a rise in crude rubber. Lead was lower as was tin. Both lard and linseed oils rose in price. The rest of the market was steady.

Aluminum has steadily dropped during the past few weeks and is now quoting 5 cents a lb. lower than 2 weeks ago. Para rubber has been picking up in price for several weeks. Last week it rose 3 cents to 68. Ceylon rose 2 cents after a fractional loss during the previous week.

To Cut New York City Taxicab Rates

NEW YORK CITY, July 10—Taxicab rates in this city are to be cut as a result of the decision of Chicago interests to combine with local ones to give service on a cash basis. According to the plans, 200 cars will be put in service and the lowering of rates will be con-

Dividends Declared

Grant Motor Co., quarterly of 1¾ per cent on preferred, payable Aug. 1 to stock of record July 15.

Continental Motors Co., cash dividend of 5 per cent, payable July 15 to holders of record July 5. Company paid stock dividends of 100 per cent in February and October last and 200 per cent in October, 1912.

Stutz Motor Car Co., third dividend of $125,000 out of earnings, equal to $1.62½ per share on 75,000 shares of the Stutz Motor Co. of America.

Curb Securities Active

—

Stutz, Chevrolet and United Motor in Demand—Entire Market Strong

NEW YORK CITY, July 11—Automobile stocks on the curb last week showed much activity and were in great demand. Stutz has been especially strong since Saturday, when it was influenced by the initial dividend declaration of $125,000 out of earnings of the company. Another curb stock which showed much strength was United Motors. After displaying weakness at the outset it made a sharp recovery, regaining all of the loss and making a further fractional advance. Chevrolet advanced on heavy buying to 228 or 13 points.

The Stock Exchange quotations were featured by a substantial rise of 19⅝ points by Studebaker common. Though the issues showed little activity, nevertheless prices held steady with few bad losses. Those that did gain showed increases ranging fractionally to five or six points.

Willys-Overland closed yesterday strong at 74¾ on rumors of an increased rate on the common and a common stock dividend. Overland directors are to meet this month and this action is expected to take place by interests down in Wall Street. The present dividend rate is 6 per cent or $1.50 per share, $25 par value. In the Spring of 1915 a 5 per cent stock dividend was declared. With the 200,000 car schedule fulfilled it is expected that the company will earn close to $20,000,000 this year. The 7 per cent dividend on the $15,000,000 preferred stock requires $1,050,000, after which above earnings will be equal to about 85 per cent on the $22,500,000 common outstanding.

—

N. Y. Organizations to Amalgamate

NEW YORK CITY, July 7—The first steps toward amalgamation of the two large automobile organizations of New York State, representing 115 automobile clubs, were taken at a meeting of the directors of the New York State Motor Federation at Rome to-day.

Appointment of a committee of five to confer with a similar committee of the New York Automobile Assn. concerning consolidation, followed the report of President M. M. Wall, of Buffalo, who was in secret conference with President Rowe of the American Automobile Assn.

Receiver for Twin City Track

ST. PAUL, MINN., July 8—Upon petition of the Standard Lithographing & Printing Co. Judge Hugo Hanft of the Ramsey county district court has named Philip Herzog receiver for the Twin City Speedway Co. The receiver furnished a $5,000 bond. Plans had already been made to put the company into bankruptcy and to have its assets sold to F. H. Wheeler, who resigned last Fall as president. Before the receiver was appointed Treasurer A. C. Gooding of the State of Minnesota was given a note for

Haibe's Ogren Wins on Grand Rapids 1-Mile Track

GRAND RAPIDS, MICH., July 8—Notwithstanding the fact that he went through the fence and drove over a pile of lumber, nearly hit the ambulance that was rushing to the spot to offer aid, and driving outside the course until he came to a gate where he could get back on the track, Ora Haibe, driving an Ogren, the same one with which Otto Henning went through the fence at Benton Harbor July 4 and suffered serious injury, lost less than one lap of his two-lap lead over Ralph De Palma and came back and won the 100-mile dirt track race here this afternoon, pulling down $1,000 in prize money for his rough ride.

The 1-mile track at Comstock Park has been an outlaw track, but the ban was lifted for one day and sanction was given by the American Automobile Assn. for the event in which eleven cars were entered, but only six started. The summary follows:

Car	Driver	Time	Prize
Ogren	Haibe	1:46:03.4	$1,000
Mercedes	De Palma	1:47:59.0	500
Stutz	Burt	1:50:27.2	300
Mercer	Andrus	2:05:14.8	200
Hudson	Mulford	Flagged	
Vernon Spl.	Kline	Flagged

Far Side Stop for Buses

NEW YORK CITY, July 10—Far side stops will be hereafter made by the Fifth Avenue buses instead of the near side as has been done for the past 15 months. According to the company, the near side stop, which worked well with trolley cars, was a pitfall for the unwary so far as the buses were concerned. Many serious accidents were narrowly averted, it was said, as, seeing a bus drawn up beside the curb on the near side, pedestrians hastened to cross the street, believing all traffic in that direction had been held up.

—

Five-Passenger Chalmers Price $1,090

NEW YORK CITY, July 10—In describing the 1917 five-passenger Chalmers in THE AUTOMOBILE for June 15, the price was given as $1,050. This was an error as the price is $1,090.

Wilcox Wins at Sioux City

—

Premier Captures 50 and 20-Mile Events—D'Alene Wins 10-Mile

SIOUX CITY, IOWA, July 8—Howdy Wilcox in a Premier finished first in the feature race here Saturday. The event was scheduled as a 100-mile race, but after driving the 10 and 20-mile preliminary events the drivers agreed to cut the distance in half. Their claim that the track was in no condition for the longer distance seemed justified and the A. A. A. officials consented to the change.

Wilcox's time for the 50 miles was 40 min. and 59 sec., showing an average of 72.57 m.p.h. His mount is fast and the slow time recorded in the feature race of the day is indicative of the condition of the course. Dave Lewis was second, Art Johnson, third; D'Alene, fourth, and Billy Chandler, fifth.

D'Alene Takes 10-Mile Race

Wilbur D'Alene, in his sixteen-valve Duesenberg finished ahead of the field in the 10-mile race. He drove a smashing race, taking the lead at the first turn, and was never headed. He was trailed by Charlie Merz in a Peugeot, Dave Lewis in a Crawford, and Howdy Wilcox in a Premier.

Wilcox got away in the second race, the 20-mile sprint, just back of D'Alene. He followed the white Duesenberg for two laps and on the third circuit just as he reached the stands passed it. He drove a sensational race and finished first with an average of 78.4 m.p.h. D'Alene's average for the 10-mile event was 79.6 m.p.h. The spectators, what few there were of them, were given a run for their money.

Because of the dense clouds of dust stirred up by the racing machines it was impossible to see what was happening on the course. It seemed impossible that drivers could pilot their mounts into the curves at the rate of 75 m.p.h. and still avoid a spill. Several times a driver was forced to turn his car into the small ditch on the inside curve to allow one of the others to pass. Hughie Hughes, in the Devlin Duesenberg, was forced out of the contest with a broken bearing. He turned three fast laps and had gone from sixteenth position to seventh when he had to quit. He had worked wonders with his car, welding a new cylinder block and manufacturing an entirely new set of bearings out of babbit. At 10 o'clock on the morning of the race the Duesenberg was scattered all over the garage.

The work was finished so that the car arrived at the track just 10 minutes before the time set for the 50-mile race. The experience of holding automobile races and of furnishing the purse by giving the driver half of the total admission was not a success at Sioux City. There were only a few more than 2000 people in the stands and the total receipts were less than $3,500, the drivers' end of the money being less than they would have received at a meet on some ½-mile tracks in this section. First money in the 50-mile race was only $408.75.

—

Must Go Over 100 M.P.H.

CHICAGO, ILL., July 6—The American speedway grand prize, for which cars must average 100 m.p.h. to qualify, will be held at the Maywood Speedway, July 29, if efforts of President D. F. Reid are successful.

—

Entries for Pikes Peak

DENVER, COL., July 7—A trio of Hudson Super-sixes are being prepared for the Pikes Peak hillclimb on Aug. 10-11-12, and two of them have been officially entered. One of these is to be driven by Ralph Mulford, and the other will be driven by F. A. Patterson, of Stockton, Cal.

The course measures 12 miles, 2200 ft., and has a rise of 6686 ft. In addition to the two Hudsons now entered, there are to date three Cadillacs, a Studebaker Special, a Peugeot, and it is expected that three Chalmers cars and several Kings now in course of construction will also be entered.

—

Cincinnati Entry Blanks Out

CINCINNATI, OHIO, July 8—Entry blanks for the $30,000 sweepstakes race to be run at the new Cincinnati speedway on Labor Day, Sept. 4, have been sent out by the Cincinnati Speedway Co. This race is one of the A.A.A. 1916 championship award events and sanction has been granted by the association. Ten place prizes are offered, the first prize being $12,000. Five hundred dollars also is offered for the leading car each of the following distances: 100 miles, 200 miles and 250 miles. The race is for 300 miles and is open to 300 cu. in. cars. Entries close midnight, Aug. 26.

—

Maxwell Factory Branch in Cleveland

CLEVELAND, OHIO, July 8—In line with the policy of the Maxwell Motor Co., Inc., of Detroit, to furnish direct factory connections in the most important buying centers, the company announces the establishment of a direct factory branch at 1828 Euclid Avenue. W. H. Keller will be branch manager.

Factory Miscellany

New Power Plant for Firestone—The Firestone Tire & Rubber Co., Akron, Ohio, has had plans prepared for a new power plant, understood to be of about 12,000 kw. capacity, or about doubling its present plant.

Pan-American Rubber Co. Formed—The Pan-American Rubber Co., Milwaukee, Wis., has been incorporated with a capital of $200,000 to make a celular pneumatic inner tire. It has established a plant in the Kopmeier Building, Third and Prairie Streets, and is already employing fifty operatives. F. J. Ramler is president and general manager.

Grand Cushion Spring Plans Factory—The Grand Cushion Spring Co., Flint, Mich., is planning a factory at the south end of Flint. L. A. Young, president of the Detroit Wire Spring Co., is interested.

Tubeless Tire Fitting Up Plant—The Tubeless Tire & Rubber Co., Millersburg, Ohio, is fitting up a large plant for the manufacture of automobile tires.

Commercial Body Company Formed—The Commercial Auto Body Co., St. Louis, Mo., has been incorporated with a capital stock of $50,000 by H. F. Cartwright and others, and will extend an existing plant, adding new equipment, largely wood-working.

First Gerlinger Truck—The first truck manufactured by the Gerlinger Motor Car Co., Tacoma, Wash., has been delivered to the Bilrowe Alloys Co., that city. The construction of the truck manufacturing plant was commenced the first of the year and the plant is now in shape to turn out from ten to twenty trucks per month. Plans have already been made to double the capacity of the plant at once.

Kissel Employees' Outing—One of the largest industrial outings to be held in Wisconsin this summer will be that given for its employees by the Kissel Motor Car Co., Hartford, Wis. The 2000 or more employees and families will travel to Waukesha Beach, Pewaukee Lake, in special trains to Waukesha, and then by trolley to Pewaukee Lake. No other Wisconsin industry has ever arranged for an outing on so elaborate a scale nor has any similar picnic crowd ever traveled so long a distance as this for an outing.

Koenig & Luhrs' First Truck—Koenig & Luhrs, Quincy, Ill., turned out this week the first complete truck produced by their new factory. It has a 35-hp. engine, will carry a 1500-lb. load at a speed of 20 m.p.h., and is equipped with pneumatic tires, electric lights and starter. Plans are being made to turn out a large number of these trucks annually.

Pullman to Build—The Pullman Motor Car Co., York, Pa., will build a plant at Grantley station, just south of this city. When placed in operation the new factory would at first employ at least 1000, which would be increased to twice this number within a short time.

Dreadnaught Tire Takes Over Old Co.—The Dreadnaught Tire & Rubber Co., Baltimore, Md., is formed to take over the assets, properties and business of the old company of similar name, but has no connection whatever with the old company. Officers of the company are: John Hiltz, Sr., president; J. P. Lauber, vice-president; Wm. C. Schmetisser, treasurer; H. James Lopper, secretary.

Milwaukee Stamping to Add—The Milwaukee Stamping Co., Sixty-fourth and Pullen Avenues, West Allis, Milwaukee, is about to award contracts for a large factory addition, to cost between $18,000 and $20,000. Plans have been prepared for a reinforced concrete and brick structure, 72 by 122 ft. The company does a large business with automobile manufacturers and also makes a general line of hardware specialties in sheet metal.

Tire Plant for Spooner—J. H. Newbury, Warsaw, N. C., and Akron, Ohio, interests, have practically closed a deal for the establishment of a tire and rubber factory at Spooner, Wis., where an enormous supply of hydroelectric current for manufacturing purposes is available at low rates. Spooner capital has decided to take an interest. It is proposed to build a new plant, the first unit of which will be 60 by 150 ft. in size.

The Automobile Calendar

ASSOCIATIONS

July 9-13—Detroit, Mich., World's Salesmanship Congress, Detroit Board of Commerce Bldg.
Sept.—Indianapolis, Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.
Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.
Dec. 2-9—Electricians' Country-wide Celebration.

CONTESTS

July 14-15—Los Angeles to San Diego, Commercial Vehicle Endurance and Reliability Demonstration.
July 15—Portland, Ore., Track Race, Northwest Auto Assn.
July 15—Omaha, Neb., Speedway Race.
July 15—North Yakima, Wash., Track Race, Hiller-Riegel Co.
July 20—Uniontown (Pa.) Hillclimb, Uniontown Motoring Assn.
July 22—Kansas City, West Speedway Race, Kansas City Speedway Co.
July 22—Oriskany Falls, N. Y., Hillclimb, Auto Club of Utica.
Aug. 5—Tacoma Speedway Race, Tacoma Speedway Association.
Aug. 11-12—Pikes Peak, Col., Hill Climb, Pikes Peak Auto Highway Co.
Aug. 12—Portland, Ore., Track Race, Hiller-Riegel Co.
Aug. 18-19—Elgin Road Race, Chicago Auto Club.
Aug. 26—Kalamazoo, Mich., 100-Mile Track Race.
Sept. 1-2—New York, N. Y., Sheepshead Bay Speedway, 24-Hour Race, Trade Racing Assn.
Sept. 4—Elmira, N. Y., Track Race, Elmira Auto and Motorcycle Racing Assn.
Sept. 4—Cincinnati, Ohio, Speedway, Cincinnati Speedway Co.
Sept. 4—Newark, N. J., Track Race, Olympic Park, Racing Assn.
Sept. 4—Indianapolis Speedway Race.
Sept. 4—Des Moines Speedway Invitation Race. Limited to six entries.
Sept. 4-5—Spokane, Wash., Track Race, Inland Auto Assn.
Sept. 16—Providence Speedway Race.
Sept. 18—North Yakima, Wash., Track Race, Washington State Fair.
Sept. 29—Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.
Sept. 30—New York City, Sheepshead Bay Speedway Race.
Oct. 7—Philadelphia Speedway Race.
Oct 7—Omaha Speedway Race.
Oct. 14—Chicago Speedway Race.
Oct. 19—Indianapolis, Ind., Race Indianapolis Motor Speedway.
Oct. 21—Kalamazoo, Mich., Track Races, Kalamazoo, Motor Speedway.
Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

GOOD ROADS

Sept. 6-7—St. Paul, Minn., Good Roads Congress, Auditorium.

SHOWS

Sept. 2-9—Columbus, Ohio, Fall Show, Ohio State Fair, Columbus Automobile Show Co.
Sept. 10-16—Milwaukee, Wis., Show, Wisconsin State Fair, Machinery Bldg.
Aug. 2-9—Hollywood and West End, N. J., Show, Atlantic Exhibition Co.
Jan. 6-13, 1917—New York City, Show, Grand Central Palace, National Automobile Chamber of Commerce.
Jan. 27-Feb. 3, 1917—Chicago, Ill., Show, Coliseum, National Automobile Chamber of Commerce.

TRACTOR

July 17-21—Dallas, Tex., Tractor Demonstration.
July 24-28—Hutchinson, Kan., Tractor Demonstration.
July 31-Aug. 4—St. Louis, Mo., Tractor Demonstration.
Aug. 7-11—Fremont, Neb., Tractor Demonstration.
Aug. 14-18—Cedar Rapids, Iowa, Tractor Demonstration.
Aug. 21-25—Bloomington, Ill., Tractor Demonstration.
Aug. 28-Sept. 1—Indiana Tractor Demonstration.
Sept. 4-8—Madison, Wis., Tractor Demonstration.
Sept. 11-16—Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.

The Week in the Industry

New England Trade Items—The Metz company, Waltham, Mass., has moved its retail branch at Boston from that city to Cambridge where it has a service department in the former home of the Ford.

The Longley Motor Co., Providence, R. I., agent for the King and Dort, has moved into its new home on Broad Street.

Frank Coveney, for some years with the Studebaker Corp. at Boston, Mass., has joined the Nettleton-Crittenden Co. agent for the Chandler in that city.

The Imperial Auto Supply Co., with branches at New York, Chicago and Minneapolis, has opened a branch at Springfield, Mass.

W. B. Hennigan, for some years with the Winton branch at Boston, Mass, is now sales manager of the Paige Detroit agency at that city.

A persistent rumor states that the Sterling Motor Car Co., Brockton Mass., has received another large war order.

Mountain Trade—The Auto Equipment, Denver, celebrated its seventh anniversary with a banquet for its employees in the Metropole Hotel last week. This wholesale supply house at 1554-1556 Broadway now has a territory of fourteen States and reports on business outside of the Denver district were made by L. E. Robinson, manager of the Colorado Springs branch, and J. R. Alexander, traveling representative. President S. T. McCollum, Treasurer S. E. Howe, Jr., and Publicity Manager A. P. Porter conducted a lively program of business betterment talks. The concern has recently enlarged its display facilities and is regarded as one of the strongest accessory houses in the Rocky Mountain region.

The Gould-Esser Co., Denver, a machinery concern at 1613 Blake Street, has secured the Colorado distributing agency for the Troy trailer.

The Mulnix & Rarie Auto Sales Co., Denver, the new name under which the firm of Mulnix & Rarie is operating in new quarters at 35 East Colfax Avenue, has taken the Roamer and Halliday distributing agencies for Colorado and Wyoming in addition to the Grant and Pathfinder agencies it has held for the same territory.

A. O. Stout, Buckingham, Col., has secured the Pullman agency for Logan and Sedgwick Counties.

The Wagner Garage Co., Denver, Kelly-Springfield and Denby truck distributor for Colorado, has had its garage at 1541 Cleveland Place appointed official service station for the Scripps-Booth.

The Steamboat Mercantile Co., Steamboat Springs, Col., has taken the Velie agency for Routt and Moffat Counties.

The C-B Auto & Service Co., Denver, a new $5,000 concern organized by W. C. Borah and C. A. and E. N. Harman, who are respectively president, vice-president and secretary of the firm, has opened a used-car and rental business at 1439 Cleveland Place.

W. Aldridge, Denver, general manager and one of the organizers of the Highway Auto Sales Co., 1435 Cleveland Place, Crow-Elkhart and Argo distributors for Colorado, has sold his interest and gone out of the motor car business.

The Vim Truck Sales Co., Denver, is the name of a new Colorado distributing agency for the Vim truck opened at 801-807 Broadway by C. F. Cole, formerly Pathfinder distributor for Colorado.

Canadian News Items—The Ford plant in Winnipeg, Man., delivered this month 300 cars to buyers. Last week, to Winnipeg owners alone, forty cars were sold.

In 1909, the first year the Ford company was there, the number of Ford cars sold in Manitoba was thirty; in Saskatchewan, twenty-one, and in Alberta, twenty-one. These were sold at a price of $1,350, without top, windshield or speedometer. Last year, 1915, the company sold in the same territory 4200 cars, as against seventy-three in 1909, at a price of $630 each, fully equipped.

This year, estimated on a basis of present sales, it is anticipated by the management of the Ford company that over the same territory they will have distributed 8000 cars, sold at a price of $570, fully equipped.

Girdwood Lamb Motors, Ltd., is the name of a new motor company just formed in Montreal and incorporated with a capital of $500,000. The three-floor building situated at 973 St. Catherine Street West has been taken as its Montreal headquarters. In addition to handling the agencies of the Maxwell and Reo cars and trucks, one of the most up-to-date repair shops in the Province of Quebec has been installed on the premises. In addition, there is garage room for 160 cars. Mr. R. F. Girdwood, one of the oldest automobile dealers in this city, has been appointed president and Mr. Lamb has been appointed secretary-treasurer.

E. J. Parker, one of the best-known automobile men in Western Canada, has taken the position of general supervisor with the Chalmers Motor Co., having jurisdiction over the territory from Fort William to the Western Coast.

The Globe Shock-Absorbing Tire Co. of Canada has incorporated at Toronto, Ont., with a capital of $1,000,000 to manufacture a resilient or shock-absorbing vehicle, automobile and commercial tire, head office to be at St. Catherines, Ont. Incorporaters are Isaac Normandy and Howard J. Ecclestone, of St. Catherines.

The F. S. Carr Rubber Co. of Canada has been incorporated at Ottawa with a capital of $200,000 to manufacture rubber, automobile and carriage fabrics. Head office to be situated at Granby, Que., and the incorporators are J. E. Day, J. M. Ferguson and J. P. Walsh, all of Toronto.

St. Louis Items—New agencies and changes in existing sales arrangements during the past week in St. Louis are:

The Newell Motor Car Co. will handle the Detroiter, this arrangement having been completed during a visit of W. H. Van Duesen, director of sales for the Detroiter Motor Car Co. The Newell company now becomes distributer for Haynes, Sun, Dort and Detroiter.

The El-car Motor Sales Co. has been designated as the distributing agency for the El-car, manufactured by the Elkhart Carriage & Motor Co., Elkhart, Ind. The territory of the company includes the St. Louis trade district.

The Fred Campbell Auto Supply Co. is exclusive sales agent here for the White Star Refining Co., Detroit, and has stocked the complete line of that company.

The John Berry Automobile Co. has become agent for the Dearborn 1-ton truck attachment. The attachment was put on exhibition Tuesday.

D. A. Livingston, well known to the trade here as a salesman, announces the organization of the Supreme Motor Co., which will begin business in this city early in August. The new company has closed a contract for the selling agency of the Simplex-Crane chassis. The company will probably handle two lower priced lines but has not determined upon these, nor has it decided definitely upon the location of showrooms.

E. E. Denniston has taken charge of the wholesale department of the Overland Automobile Co., St. Louis. Mr. Denniston comes from Buffalo, N. Y., where he was distributer for Stevens-Duryea and later conducted a truck-body-building plant. Here he succeeds H. A. DeWitt, who resigned as sales manager.

Nash Takes Over Jeffery

Together with Lee, Higginson & Co., Purchases Entire Stock of Company

Kenosha, Wis., July 14—C. W. Nash, who is just retiring from the presidency of the General Motors Co., and Lee, Higginson & Co., of Boston, who financed the General Motors Co. several years ago, have purchased the entire stock of the Thomas B. Jeffery Co., makers of passenger and commercial vehicles. The purchase price is said to involve about $9,000,000, which would mean about $300 per share, as the Jeffery company is capitalized at $3,000,000.

To Continue Line

Mr. Nash retires from the business of the General Motors Co. on Aug. 1 and after that date will take up active management of the Jeffery business. At a recent meeting of the department heads of the Jeffery company, at which Mr. Nash was present, plans were made for the active continuance of passenger cars and trucks. Charles T. Jeffery, Harold W. Jeffery and Thomas M. Kearney, who make up the present board of directors, will continue on the board, at least for the present.

Another Combine Possible

No further details could be secured from Mr. Nash, and probably none will be made public until after the next meeting, which will be held in Boston on July 19. Predictions, however, are being made that the connection of Mr. Nash with the Eastern banking syndicate means the re-entrance of this group into automobile manufacturing and that the Jeffery purchase is only the first step in the formation of another big automobile combine.

The Jeffery company is one of the largest motor car plants in the Middle West. It was founded 17 years ago as a bicycle plant by the late Thomas B. Jeffery of Chicago. One of the products with which it has achieved considerable success during the past few years is the Jeffery Quad a four-wheel-drive truck which has been used extensively for military purposes both in this country and abroad.

23,879 Carloads June Shipments

New York City, July 18—Shipments of automobiles in June totaled 23,879 carloads, according to figures given out by the National Automobile Chamber of Commerce, which met at the Detroit Board of Commerce last week to discuss the freight situation. This figure compares with 17,075 carloads in June, 1915. For the 6 months ending June 30 shipments totaled 151,163 carloads compared with 89,613 carloads for the same period in 1915. It was also estimated that the earnings of railroads from shipments of finished products alone from automobile and truck factories will exceed $35,000,000 for the current year.

The meeting was interested particularly in subjects considered by the official classification committee at its meeting here to-day. This committee fixes the rates used by railroads east of Chicago and on its docket for the New York meeting are the ratings for speedometers and connections, lamps used on automobiles, magnetos, automobile trunk racks, automobile doors, dashes, wheel rims, steering wheels and most important of all, automobiles, passenger and freight. The automobile men approved some of the proposed ratings but were opposed to the ratings suggested by the classification committee on lamps, steering wheels and single automobiles and trucks.

Lamps would be rated 50 per cent higher than electric lamps for other uses and single trucks considerably higher than at present. It is claimed by the automobile interests that there is no justification for these changes. They will also ask for a specific rating on automobiles and trucks when boxed in carloads, as such shipments are now charged the same as when not boxed.

Dealers' Upheaval in New York

Silver Takes Chalmers—Overland Opens Branch—New Mitchell Sales Co.

New York City, July 17—Broadway's automobile row has experienced the greatest changes in the last few days that it has had for years, the Overland, Chalmers and Mitchell agencies all figuring in the changes. C. T. Silver, who has handled the Overland and Willys-Knight for many years, has discontinued them and taken the Chalmers agency, the Chalmers branch having been discontinued. The Overland company is establishing a branch and has in the meantime opened temporary quarters in the Circle Building on Broadway with E. B. Jackson, formerly manager of the Packard company of New York, as manager. A new organization, the Mitchell Motors Co. of New York, has been formed to handle the retail Mitchell sales in the metropolitan territory and the Carl H. Page company, which previously handled the Mitchell, will in future confine its effort to the wholesale end of the Mitchell in part of this territory. Mr. Jackson has been succeeded as Packard manager by Emlen Hare, who for some time has been in charge of the special truck department of the Packard company here. Further, George Stowe, who has managed the Chalmers branch here, has taken charge of the sales in the newly formed Mitchell Motors Co. of New York.

The Willys-Overland company's direct factory branch for the direct sale of Overland and Willys-Knight cars follows the policy already put in force of establishing its own branches in the most important cities in this country.

The Overland company has had in progress the erection of one of the largest service buildings in this territory with a view to taking over its own business, locating a temporary showroom at

S. A. E. Meets in Washington

First Standards Meeting Under Government Auspices Held at Bureau of Standards

WASHINGTON, D. C., July 18—For the first time the Society of Automobile Engineers has taken an officially recognized place in the work of national standardization. This was on the occasion of the meeting of the newly-appointed aeronautic engine division of the S. A. E. standards committee which met here today at the Bureau of Standards, representatives of the Bureau, of the army and navy and of the aviation industry being present. The chief business was to discuss the program of the division which was created because the army and navy authorities consider it vitally important that many things in connection with aeroplanes should be standardized with the greatest rapidity possible. The meeting was in every way a success, and it is obvious that the most vital matters will be handled very quickly.

The meeting was opened by Dr. S. W. Stratton, director of the Bureau of Standards, who made a short speech of welcome. He spoke regarding the great importance of the work which the S. A. E. were about to begin and stated that the bureau with its splendid equipment for testing, would be able to undertake a good deal of research work which would be necessary. Henry Souther, chairman of the aeronautic engine division and consulting engineer to the U. S. signal corps, then took charge and an immediate start was made on the more pressing problems.

The S. A. E. was represented by Howard E. Coffin of the Naval Consulting Board, A. Ludlow Clayden, chairman of the standards committee, and Coker F. Clarkson, general manager. Among members of the division well known in the automobile world were F. S. Duesenberg, designer of the Duesenberg racing motor; A. F. Milbraith, Wisconsin Motor Co., and H. M. Crane, Simplex Automobile Co., each of whom has been building aircraft engines. Another S. A. E. member who has been prominent in the flying field, Glen Martin, took a prominent part in the discussions as did Elmer S. Sperry, a prominent member of all the aeronautic societies and of the Naval Consulting Board. Captain Clark of the army aviation department and Lieutenant Richardson of the navy also spoke repeatedly, throwing much light upon troubles encountered in the use of aeroplanes.

Owing to the continued full power running of aeroplane engine spark plug troubles are prominent and several ignition experts, notably the Bosch company, consider that the small metric plug is better suited for heavy duty than the ⅞-in. S. A. E. standard. The idea is that the thinner shell allows the heat to escape more readily from the insulator. That practical experience bears out the contention was soon obvious, but some doubt remains because most experimenters change the make of plug at the same time as the size. The general opinion, however, was distinctly in favor of the small plug and it is expected to settle the question at the next meeting to be held in about 30 days.

Next arose a long discussion on the possibility of creating a standard propeller hub, so that only one size could be used for all aeroplanes. Some members contended that this was impossible, but it is understood that a standard hub is being used in France, so one or two sizes should take care of all requirements in America. The meeting voted to send blueprints of the French standard to all interested parties for comment on its desirability as a standard.

What Is Right-Hand Motion?

A somewhat involved argument took place on the definition of a right-hand or left-hand engine. It is necessary to define the viewpoint and, even if this is done, there remains the difficulty that propellers are right and left-hand pitch and in some cases a left-hand pitch propeller might go on either a right or left-hand engine. The difficulty was solved by adopting a definition standardized by the electrical industry, which states that direction of revolution shall be described as clockwise or counter-clockwise, the observer standing looking at the driving pulley with the motor behind the pulley. In other words, an automobile engine would be a counter-clockwise engine because its rotation is counter-clockwise when looking at the end from which the power is taken.

—

N. A. C. C. Mid-Summer Meeting at Christmas Cove

NEW YORK CITY, July 18—Alfred Reeves, general manager of the National Automobile Chamber of Commerce, has left this city for Christmas Cove, Me., to attend the mid-summer meeting of the Chamber at Clifton, Samuel Miles' summer home.

The meeting will be held on July 25 and the directors will leave on the next day. Following are those invited:

Hugh Chalmers, R. D. Chapin, Hudson; C. W. Churchill, Winton; Chas. Clifton, Pierce-Arrow; T. Walter Drake, Hupp; C. C. Hanch, Studebaker; Wilfred C. Leland, Cadillac; Alvan Macauley, Packard; W. E. Metzger, Argo Electric; R. E. Olds, Reo; Carl H. Pelton, Maxwell; H. H. Rice, Waverley; Windsor T. White, White; John N. Willys, Willys-Overland; Col. George Pope, A. L. Riker, Locomobile, and Alfred Reeves, general manager, together with some personal friends of Mr. Miles.

Eclipse Entitled to Bijur License

Disputed Contract of License Declared Valid—Appeal To Be Made

BUFFALO, N. Y., July 14—The Eclipse Machine Co., Inc., Elmira, N. Y., and Vincent Bendix, Chicago, have been awarded the decision in their suit with the Bijur Motor Lighting Co., Hoboken, N. J., Judge Hazel rendering the decision in the district court here to-day. The suit was brought by the Bijur company in 1914 for infringement of its patent on a starting motor gear, contending that the Bendix gear used in motor starting apparatus infringed patent No. 1,095,696 granted to Joseph Bijur in May, 1914.

Previous to the suit an alleged contract was entered into between Vincent Bendix and Joseph Bijur by which Bendix and the Eclipse Machine Co. were given the right to manufacture the Bendix drive device under the Bijur patent. The suit largely centered around this contract, which was declared by the Bijur company to consist only of tentative arrangements intended to be subsequently embodied in an agreement. Judge Hazel decided otherwise, holding that the contract fairly expressed the intention of the parties and was without ambiguity or indefinitiveness.

A second point of importance in connection with the contract was that it bore the signature of Joseph Bijur, president of the Bijur Motor Lighting Co., and that it had not been passed upon or authorized by the board of directors. The court held that the signature of the president was sufficient to make the contract valid, in that the president has both presumptive and actual authority to bind the company by the contract to which he agreed. The court declared the contract valid and that the Eclipse Machine Co., and Mr. Bendix were entitled to a license under the Bijur patent.

The Bijur Motor Lighting Co. intends to have Judge Hazel's decision reviewed on appeal which will be taken at once.

The case is of unusual interest because the type of drive for starting motors involved in the suit is now in almost universal use on American-built cars. The Eclipse Machine Co. commenced the manufacture of these devices in January of 1914, under a license from the inventor, Vincent Bendix of Chicago, and in May, 1914, a patent for a similar device was issued to Joseph Bijur. By the disputed agreement Bendix and his licensee the Eclipse Machine Co. were given rights to manufacture the device under the Bijur patent as well as under the Bendix invention. Soon after this the Bijur company brought suit.

5000 Tractors for Texas

Farmers Ready to Purchase at 1916 Tractor Demonstration in Dallas

By S. P. McMinn
Staff Correspondent

DALLAS, TEX., July 18—*Special Telegram*—More than 12,000 people witnessed the opening of the national circuit of farm tractor demonstrations here to-day. The city is thronged with farmers and their families, many of whom came in their automobiles, and all interested in tractors, either contemplating an immediate purchase or investigation with a view of buying machines for use on their farms. Around the field on which the demonstrations were held 350 automobiles were parked and many more were continually driving up. It is expected that fully 200,000 persons will witness the demonstrations here before they are concluded.

The farmers of Texas will purchase 5000 farm tractors in 1916. Last year Texas farmers bought upward of 1700 tractors, and in the past three seasons tractor manufacturers and dealers have disposed of more than 3300 machines in Texas.

With the formal opening of the first of the 1916 national tractor demonstrations here to-day this city is crowded with farmers who are ready to purchase machines and with motor car dealers and garagemen who are ready and willing to complete arrangements to do business with the farmers. One big distributer of automobiles already has signed up to distribute tractors. This is the Frawley Motor Co., distributer of Reo and Briscoe cars. The Frawley company has contracted to distribute throughout the entire State of Texas, and possibly also Oklahoma, the Denning tractor produced by the Denning Tractor Co., Cedar Rapids, Iowa.

It is reported on good authority that at least four other big automobile distributers, and possibly five, will make similar connections with other tractor concerns this week. The Dallas demonstration is held on the Caruth farm, of 1000 acres, near the city. There are now ninety-five tractors on the ground.

Hutchinson, Kan., Next

The demonstration will be formally opened to-day, and every day until Friday there will be public demonstrations of power plowing, disking, harrowing, cultivating and the use of tractors for other farm work, such as ensilage cutting, wood cutting, pumping, etc. Saturday the entire demonstration will be moved in special trains to Hutchinson, Kan., and from there to the other centers included in the circuit.

PAUL SMITH

Paul Smith, Chalmers Sales Manager, Dies from Fall

NEW YORK CITY, July 15—Paul Smith, vice-president and general sales manager of the Chalmers Motor Co., Detroit, Mich., died to-day after falling from the window of his room on the tenth floor of the Hotel Biltmore.

Mr. Smith had just completed a $6,000,000 deal with C. T. Silver for the transfer of the local agency of the Chalmers company. He was suffering from an attack of ptomaine poisoning which is said to have had nervous complications.

The position of vice-president of the Chalmers company had been held by Mr. Smith for the last 2 years.

He was 33 years old and born in Maine. He was educated at the University of Illinois to be a physician. Ten years ago he was a physician in Columbus, Ohio, but for only a short time. From there he went to Detroit, working as a day laborer in an automobile plant. Shortly after this he became Columbus agent for the Goodyear Tire & Rubber Co. While he was sales manager for the Goodyear company in New York City, Mr. Flanders became interested in him and made him sales manager for the E.M.F. Co. This was in 1909. In 1911, he assumed the same position in the E.M.F.-Studebaker Co. In 1912 he organized the Flanders Motor Car Co., and the following year joined the Lozier forces. It was in 1915 that he became associated with the Chalmers organization.

Mr. Smith was a member of the Detroit Athletic Club, Fellowship, Harmonic, Racquet, Anchor, Curling and other clubs of his home city. He also had served as a first lieutenant in the First cavalry of the Illinois National Guard. Besides the widow, he is survived by a daughter.

Plan Greater Sales Efficiency

Nation's Leading Business Men Form World's Salesmanship Congress

DETROIT, MICH., July 13—Greater efficiency in industry through greater efficiency in salesmanship is an object of the World's Salesmanship Congress which concluded a 5-day session in this city to-day. The organization was rounded into a permanent form with an attendance of nearly 3000 and plans to proceed actively with its work for better conditions in business and merchandising.

Able addresses were delivered by a large number of executives from all parts of the country and from many lines of industry, although the motor car men predominated in leadership because the science of selling has been well developed by them and because the idea of the Congress originated in Detroit, the automobile capital. One of the first steps discussed was an effort to have established selling courses in existing schools and colleges. Better and more complete text books on selling are desired and an effort is to be made to classify all selling knowledge brought out by the addresses and discussions at the Congress.

For a continuance of the work and the permanence of the organization, Norval A. Hawkins, general sales manager of the Ford Motor Co., was made president. The vice-president is Bartley J. Doyle, president of the Keystone Publishing Co., Philadelphia.

The Executive Board represents various line of business and is made up of:

President, Norval A. Hawkins, general salesmanager, Ford Motor Co., Detroit.

Vice-president, Bartley J. Doyle, president, Keystone Publishing Co., Philadelphia.

Secretary-manager, to be selected by board.

John Wanamaker, New York and Philadelphia.

John H. Patterson, president, National Cash Register Co., Dayton, Ohio.

Edward A. Woods, president, National Association of Life Underwriters, Pittsburgh.

Hugh Chalmers, president, Chalmers Motor Co., Detroit.

B. P. Neff, secretary, F. A. Patrick Co., Duluth.

Harry W. Ford, president, Saxon Motor Co., Detroit.

Harry M. Jewett, president, Paige-Detroit Motor Car Co., Detroit.

Joseph Mack, president, Joseph Mack Printing House, Detroit.

Nearly 3000 salesmen and business executives registered at the Congress, and it is planned to raise $100,000 for the promotion of the work.

The Congress opened Sunday, July 9, with addresses in 18 Detroit churches

754,902
Passenger Cars Made in First 6 Months of 1916

Ninety-Nine Factories Contribute — 96 Per Cent Made in Michigan, Ohio and Indiana—Ford Alone Makes 298,000, Overland 94,477, Others Over 40,000

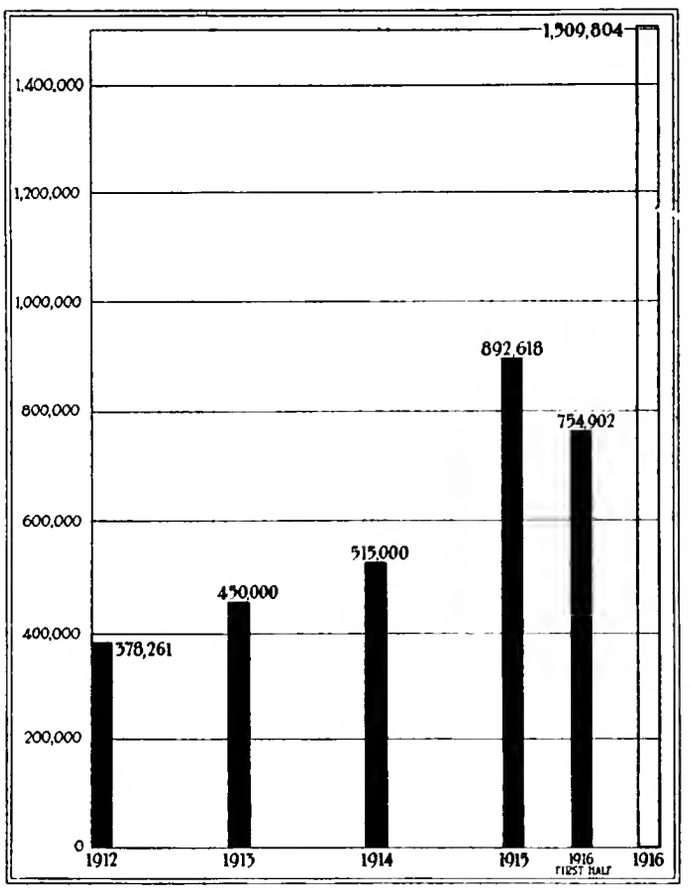
By J. Edward Schipper

WHEN Jan. 1, 1917, marks the beginning of a new year, more than 1,500,000 passenger cars less than a year old may be traveling the roads of the United States, or will have been shipped to other lands. This prediction is not based on estimates but upon the fact that **during the first six months of 1916 or the period closing on June 30 at midnight, 754,902 passenger automobiles had been completed in American factories.**

In all factories throughout the country practically without a single exception, the rate of production is being increased at the present time. During the year, from July 1, 1915, to July 1, 1916, many production records were shattered by concerns which had installed new methods of manufacture and new machinery. During the year period mentioned 1,300,000 cars were completed, and this enormous production was made in spite of difficulties which were more severe than those encountered for many years. This is particularly true regarding the shortage of raw materials and the difficulty of securing adequate quantities of labor.

Ninety-nine automobile factories produced passenger cars during the first six months of 1916. Of this number 27 are located in Detroit and immediate vicinity. Twelve are in Ohio, twelve in Indiana, and the remainder scattered about the country almost from coast to coast. Of the 754,902 cars made during the first six months of 1916, 96 per cent were made in the three States of Michigan, Ohio and Indiana. Of this, of course, Michigan claims the lion's share with the great plants centering about Detroit. Seventy-nine per cent of all the cars made in this country from January to July were made in the Wolverine State, or 595,153 in actual figures.

Ohio ranks second as a car-producing State, having made 15 per cent of the total, or 111,946. Indiana made 2 per cent during the first 6 months, giving a total number of 15,110. The remaining 4 per cent of the factories were well scattered, with a fair share in Illinois, New York and Wisconsin, where the natural railroad facilities lend themselves to the quick delivery of materials and also render possible good shipping facilities for the finished product. Both of these factors are extremely necessary to the big producing concerns, particularly as regards shipping the cars, because each car takes up such a large percentage of space in a freight car, thus necessitating a great number of freight cars to take care of even the daily product of some of the large concerns which have schedules up as high as 1,000 a day and more.



Production chart showing how first 6 months of 1916 compare with entire years of previous manufacture

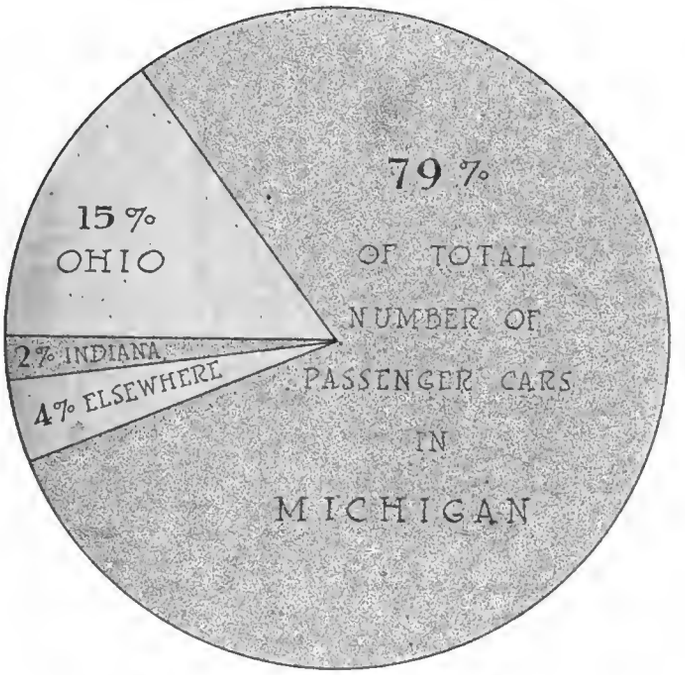
Ford leads the list of big producing concerns, with a record of 298,000 cars in the first 6 months of 1916. During the one year period of July, 1915, to July, 1916, more than 477,000 Ford cars or the parts to as-

semble them left the shipping department of the Highland Park factory. Second in order of production, as far as quantity is concerned, is the Willys-Overland plant at Toledo. This concern produced 94,477 cars during the first 6 months of 1916 and more than 150,000 during the year ending July 1, 1916. Third in production order is Maxwell, with more than 40,000 for the 6 months' period and approximately double that number for the 12 months ending July 1, 1916.

Other big producers are Chevrolet, Buick, Dodge and Studebaker, with more than 40,000 for the first mentioned and between 30,000 and 40,000 for the others for the 6 months' period. There are a great many concerns ranking between 10,000 and 20,000 for the 6 months, and among them may be mentioned Chalmers, Hudson and Saxon. With practically all these companies production activities have been such that during the first 6 months of 1916 many more cars were made than during the last half of 1915, so that the total production figure for the year ending July 1, 1916, is less than double that of the 6 months then ending.

Difficulties During Period

During the last half year, the difficulties that have beset car makers, as far as materials and labor are concerned, have by no means disappeared. At the same time, manufacturing schedules and material orders and deliveries have been adjusted to the circumstances, with the result that on the whole it can be truthfully said that production is progressing more uniformly than during the greater part of 1915. Deliveries of materials are more regular and in a great many instances manufacturers are now stocked with large quantities of the very parts that delayed them during the early stages of the present situation.



Ninety-six per cent of American cars were made in the three States of Michigan, Ohio and Indiana

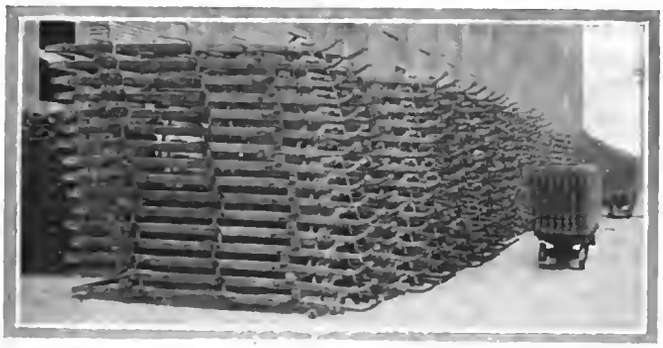
Where the improvement can best be noted is in the plants which assemble their cars from parts bought from individual manufacturers. These concerns had the greatest difficulties because a missing part would tie up the entire product and absolutely check deliveries. For instance, one concern in Indiana was unable to secure any motors except in groups of two and three for a period of three months, with the result that large numbers of completely assembled chassis minus the motors were lying useless in the plant, taking up valuable space and representing loss on the invested capital. Another concern was in practically the same position in regard to rear axles, while it had plenty of motors. Another concern found it practically impossible to secure radiators. Another had trouble with bodies, and thus it has gone throughout the entire gamut of parts. A factory would be overstocked with a certain part and would lack another, while practically next door a concern manufacturing a similar grade of cars would have plenty of the parts needed by the other concern and be short on the parts of which the first concern had plenty. It is this situation which has been considerably adjusted and which has ceased so seriously to interfere with shipments.

Although the material situation has been felt by the concerns which manufacture practically all their own parts, these are in a way more elastic. Taking motors, for example, a manufacturing concern would never be troubled to secure an entire motor, although it might be hard to secure adequate quantities of certain parts for the motor. On the other hand, assembling concerns, in many instances, were held up because they could not secure any motors at all. The completion of war material contracts by many of the steel consuming plants has no doubt tended to further relieve the market.

Statistics of Industry

Some of the statistical figures of the automobile industry are entrancing. They form a romance of big business and prodigious capital that has never been equaled in the history of the world. When it is noted that one concern alone turns out, in a half year, over $119,000,000 worth of cars, it seems almost beyond comprehension that there should be any room for other manufacturers, and yet there are ninety-eight others not turning out as many but practically all prosperous and all with definite manufacturing schedules. During the year of 1915, from January 1 to December 30, 892,618 cars were produced. This seems like a tremendous number and yet, during the first half of 1916, 85 per cent of that total have already been made. In 1914, 500,000 cars were manufactured; during the first half of 1916 that many and more than half again as much have been shipped.

Studying the production curve, almost the opposite conditions from what one would imagine would be true actually obtain. Starting with 1903, when cars first came into general demand, it would be thought that the demand created would cause an overwhelming production until the immense market was overtaken to some degree. Yet, it was not until 1909 that production actually reached 100,000 cars per year. In 1910, it had increased to 200,000, and in 1911 an actual fall-off in rate of increase is noted. Three hundred thousand cars per year was reached in 1912, and 500,000 in 1914. Here the curve takes



Overland factory. Less than one day's output, showing how much stock is required to keep up with a production capacity of 1000 cars a day

a sharp upward bend and the rate of production far exceeds anything that has gone before. Predictions of 1,500,000 cars for 1916 do not seem far amiss, even though this is an increase of more than 55 per cent over 1915, or in actual numbers, 500,000 more cars made this year than last.

The total retail value of the passenger cars built in the United States in 1915 was $565,856,450. Thus far in 1916, or for the period of the first half year, the retail value of the passenger cars is in excess of $481,100,000. These cars have already been actually sold, and in many cases manufacturers have more than sold their output for the first six months and are having difficulties in keeping up with the delivery schedules to their different dealers. This is caused, of course, both by the material shortage and by the fact that the dealers have sold more cars than their original schedule called for. It is quite true that the second reason has had practically as much influence as the first, although it is also true that more than one concern has lost as much as 45 actual days from their manufacturing schedule during this same period of time, due to movements of plant location and other disturbing factors. In fact, during this year there has been an unusual amount of factory and plant movements, as well as expansion.

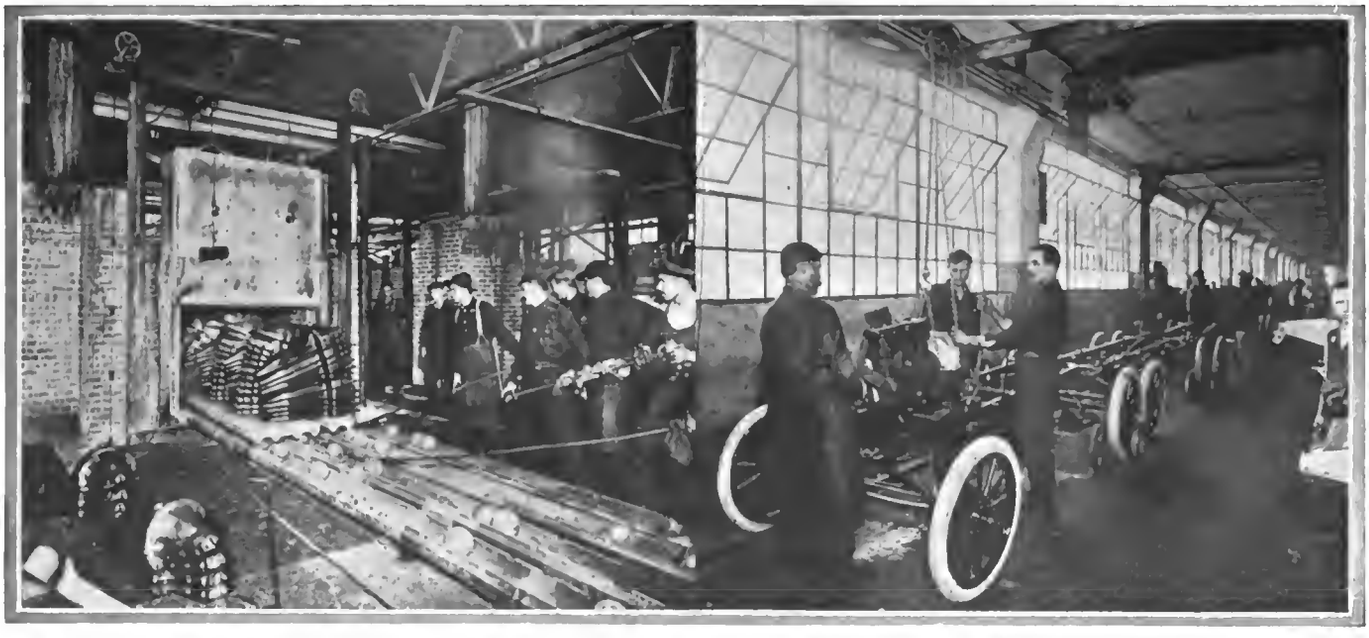
Many Add Floor Space

The addition of new floor space to a factory necessitates expanding into the new room and very often entails a rerouting of the product. There is no doubt but that at least 60 per cent of the larger manufacturing concerns have had to perform the difficult feat during the past six months of continuing their production schedule while rearranging the plant. Many new buildings have been added and many are now under process of erection. To give a few examples, the Ford company is practically doubling its factory area and predictions are made of a manufacturing schedule of 1,000,000 cars a year. In Indiana, the National company, for example, is putting up a new building and will shift into it without stopping manufacturing. Marmon, likewise, has bought new acreage. The Overland company is continually making additions to its plant and even now is just about completing a large new office building. Other plants which are adding space are Inter State, Jeffery, Haynes, Chandler, Hupmobile, Saxon, Scripps-Booth and a score of others. In practically every instance where these increases have been completed and occupied as part of the regular production plant, the change has been made without shutting down, with only a slight delay.

One of the most important problems in connection with the work of a big production concern is that of distribution. It is necessary to know the territory and the people in which the cars are to be sold, and therefore data which would tend to bring out information regarding which states are increasing fastest in number of cars, or, in other words, which are buying most, is of greatest interest. It has been said that the farmer is the greatest car purchaser of to-day, and this seems borne out when it is noted that Ohio bought more cars than any other state during the last half of 1915 and the first half of 1916. Actual figures cannot be given for increase up to July 1, 1916, but for the six months ending Jan. 1, 1916, the number of cars in Ohio increased by 58,802, or 48 per cent over its previous number.

Farmer the Greatest Car Buyer

The farmer is all-important as a car buyer. In Oklahoma, the increase of cars for the year of 1916, as compared with 1915 insofar as figures can be compiled at the present time, is 250 per cent. In Mississippi it is 195 per cent. In Louisiana, 210 per cent, and in Idaho, 117 per cent. In the great farming State of Iowa, there is one car to every fourteen persons; in Nebraska, one to every twenty persons, and throughout the other big farming states on the corn and wheat belts similar conditions prevail. The county fair of to-day is incomplete without its attending automobile exhibits. And unlike many of the pretentious automobile shows held, the farmers actually come to buy as well as to look.



Ford Methods—Ball carriers permit the trays to be rolled out of the furnace. Motors are lowered on to the completed chassis

In summing up this farm situation, a vice-president of one of the largest producing concerns approaches the situation from an interesting angle. He says, "The average value of the 7,000,000 farms in this country is $6,500. The owners of 1,000,000 of these farms have automobiles. At least 3,000,000, or one-half of the remaining farm owners who do not drive cars, are good prospects." In other words, according to this estimate, the entire output of 1916, or 1,500,000 cars estimated, could readily be absorbed by the farmer prospects alone. Estimating on this same basis of income, the same authority finds that there are 2,500,000 city people who are prospects for new cars.

Both of these estimates are for people who have never owned a motor car. They are first-time purchasers, and this does not take into consideration the ever-increasing percentage of those who are buying their second, third or fourth car, or those who own more than one.

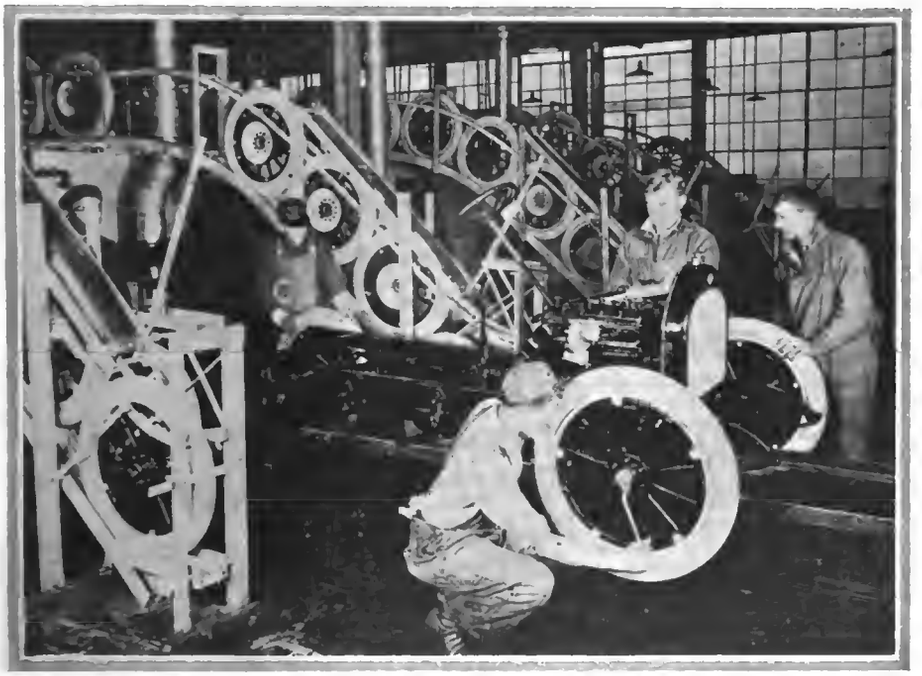
The fear that present big production schedules will saturate the market seems ungrounded when actual conditions are closely scanned. Throughout the industry, the close of the first six months of manufacture finds an optimistic current of thought in the minds of those whose business has been adapted to the modern methods of intensive manufacture, coupled with economical management. Both in the two well-defined fields of assembled and manufactured cars, the economies which have resulted from the use of up-to-date methods have enabled the product to be marketed at a profit in spite of conditions which otherwise would have been disastrous. The producers of assembled cars have reaped the benefits of the production methods in use in the parts plants, which have enabled these parts manufacturers to produce cheaply enough to allow the assembler who proceeds along modern lines the necessary margin of profit.

During the 6 months ending July 1, 1916 the number of passenger cars exported to foreign countries has been in excess of 33,000 and valued at more than $24,000,000. Detailed figures are not as yet available for the month of June, but from January until the end of May the average monthly exportation was 5645 cars and the average value of the car shipped abroad was $4,059,878 per month. The exact totals of the passenger cars shipped from the country during the 5 months ending June 1, 1916, was 28,227 cars valued at $20,299,393.

During the first half of 1916 the number of passenger cars made per month in the United States averaged 125,817. With the average monthly exportation of 5645 just about 4½ per cent of our total passenger car production is shipped abroad. Uncle Sam probably will always continue to be his own best customer, but the markets of the world are open to him and the probabilities are that the close of the European conflict will open large markets which are now inaccessible. It is of course natural to assume that the home industries of Europe will be protected, but if conditions are as they might be expected to be the market for automobiles will be larger than the recreated European factories can handle.

To sum up the situation, the 754,902 cars which have been made have practically all been sold, and in many sections of the country dealers are already clamoring for their share of the other 700,000 which are to be manufactured during the remaining 6 months, and when the year of 1916 shall come to a close, if present conditions hold until the end, the United States will have been enriched by the possession of considerably more than $1,000,000,000 worth of cars.

The prosperous condition of the automobile industry has been reflected in other lines. The companies selling manufacturing machinery have been rushed as never before. High-speed steel necessary for fast cutting and big production is at a premium and all along the converging pathways of manufacture the story has been the same, "Give us men, give us materials and give us machinery—we can use them all."



Overland factory. Wheels fed by magazines to the required points

Left—View in Maxwell factory. Each body is a step nearer completion. They are moving gradually to the point where they will be picked up by an electric hoist and set on their chassis, as the latter reach that point in their growth into complete automobiles. Right—Painted chassis just entering the drying oven. In 30 min. the moving chain will pull it out dry at the other end, and the work of assembly will continue again. Another follows it only a few feet away

Buick Returns to Four

Entirely New Small Car Added to Line —The Little Six Continued Unchanged

Front view of the new Buick four-cylinder touring car

AFTER giving up entirely for a time the manufacture of four-cylinder cars, the Buick Motor Co., Flint, Mich., is again to put them out, in addition to continuing without change the production of the little six-cylinder model that made such a hit during the past season. Reversions to fours by so large a manufacturer might be taken as a significant move, and indicates that there is a big demand for a moderate-priced vehicle of this type.

The new Buick four, which, needless to say, is to be made in large numbers, follows characteristic Buick design throughout, with perhaps more alteration in the engine than elsewhere, although that unit is a valve-in-head type as are other power plants of this make. It will sell at $665 as a touring car under the model designation of D-35, and as a roadster it will be priced at $650 and known as model D-34. In its general lines, especially the radiator, the new car is typically Buick. It has a wheelbase of 106 in., and there is plenty of room for five passengers.

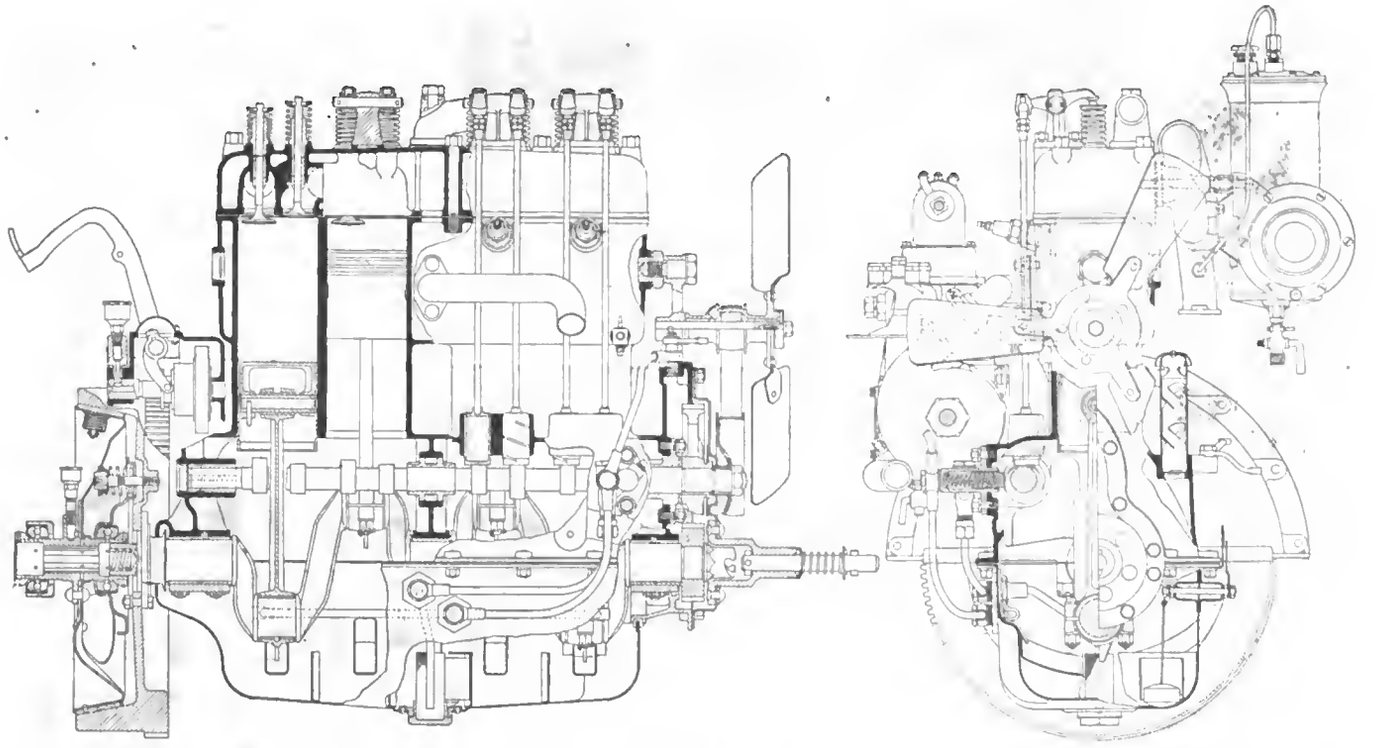
Thirty-five brake horsepower is claimed for the engine, which has a bore of 3⅜ in. and a stroke of 4¾ in., giving a displacement of 170 cu. in. and a formula rating of 18.2 hp. These cylinder dimensions are not a great deal different than those of the little six, which has a bore of 3¼ in. and stroke of 4½ in.

Other specifications of interest are the pump cooling; Marvel carbureter in conjunction with rear tank and Stewart vacuum feed; Delco combination starting, lighting and ignition; cone clutch; three-speed gearset in unit with the engine; driveshaft inclosed within a torsion tube; three-quarter floating rear axle; semi-elliptic springs both front and rear; and 31 by 4 non-skid tires all around.

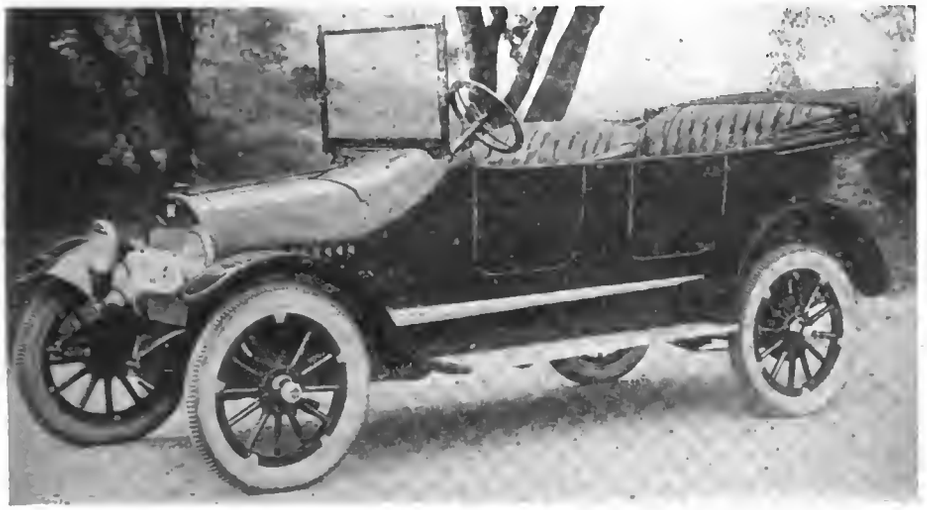
Has Detachable Head

Although the engine is an overhead valve design, it is probably the one part that is most at variance with previous construction, in that the cylinder head is detachable as a unit with the valves. It will be remembered that previous Buick construction has been to have the heads integral with the body of the cylinders, and to use valve cages, which, when removed, brought out each valve individually. The new design makes it possible to get at the valves when the head is taken off, and at the same time gives a free opening into the cylinders and pistons. The valve springs and rockers are not inclosed, but are quiet due to the lubrication provisions and the interposing of a felt pad at the ball end of the push rod, as in previous designs. The rocker shaft supports are bolted to the head casting, and this also carries the water outlet connection.

In the design of the head, special provision was made for the proper cooling of the valves, the water passages surrounding the pockets being large. On the whole, there is



The new 3⅜ by 4¾-in. Buick four-cylinder engine in section. It has a displacement of 170 cu. in. and is claimed to develop 35 brake hp. Note the characteristic overhead valves and the pump cooling



Buick five-passenger, four-cylinder touring car which sells for $665. It has a 106-in. wheelbase and uses 31 by 4-in. tires

nothing radically different in the design of the motor as compared with the conventional overhead-valve, removable-head job, yet the details have been worked out to give a surprisingly compact whole.

In its general arrangement, the motor has its push rods on the right, and both intake and exhaust manifolds occupy the left side. On the push-rod side is mounted the Delco single-unit starting and lighting outfit with ignition distributer integral. This motor-generator is driven off the pump shaft, which in turn is operated by a helical gear meshing with the camshaft gear. Mounted directly on the motor on the manifold side is the vacuum tank, and below it the carbureter, giving a very short feed pipe between tank and carbureter, with obvious advantage. The upper half of the flywheel is housed over by an extension of the upper portion of the crankcase, which is integral with the cylinder block. This extension meets an extension of the gearbox, and the two bolt together by means of a flange, giving a substantial support to the gearset and kindred parts without excessive weight.

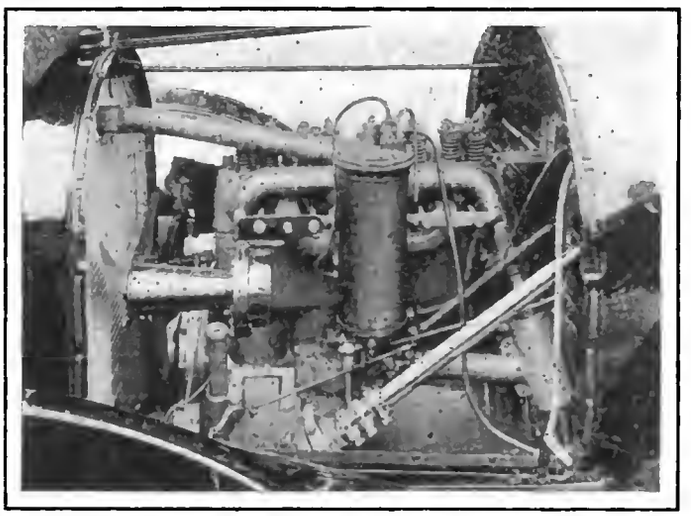
Large Valves a Feature

There are three main crankshaft bearings and an equal number carrying the crankshaft, both of which parts are of sturdy section so as to reduce the vibration and make a smooth-running engine. Valves are quite large—1½ in. diameter—and the gas passages are as direct as possible, both features being power-giving factors. Conventional connecting-rods of I-beam section, and pistons carrying three rings each are fitted, the wristpins being pinned to the pistons so that the upper rod end has a bearing on the wristpin.

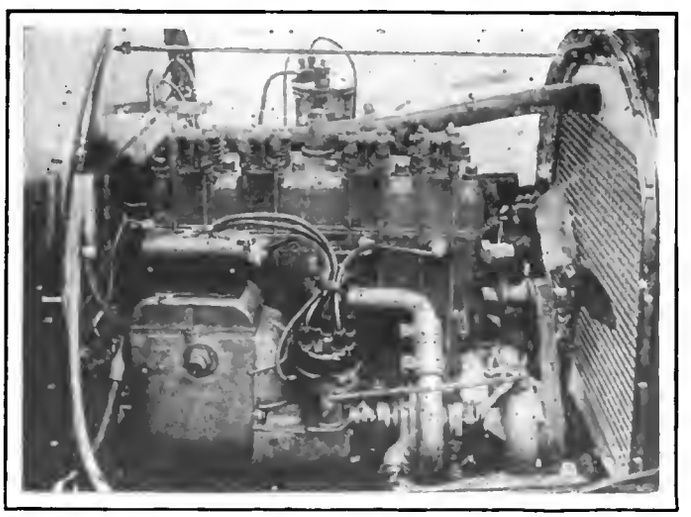
Much attention seems to have been given to working out the cooling system, as evidenced by the wide water spaces, and the carrying of the cylinder jackets well down to within about 1 in. of the bottom of the piston stroke. The water spaces in the head are extra large, and it would seem that warped valves due to heat are an impossibility. There is a three-blade pressed steel fan, belt-driven from a pulley on the end of the camshaft, with provision for adjustment of the belt tension through the rocking fan bracket that attaches to the front of the cylinder casting proper. The centrifugal pump delivers the water to the center of the cylinder block on the right side, and the passages insure even distribution all around. The cellular-type radiator is of generous proportions for this engine, and should have no trouble in caring for its needs.

Likewise, care has been expended on the design of the lubrication arrangements. Oil is drawn from the pressed-steel under part of the motor by a cam-operated plunger pump, delivered through a supply pipe to each of the troughs under the connecting-rods and also through a special lead to the timing gears at the front. It is then splashed in the usual way to the various bearing surfaces by the dipper on the end of the rod. The troughs are curved so as to follow the rod end for a considerable distance beyond its dead-center position on either side, taking care of any difference in level between one side of the car and the other. On top of each a connecting-rod upper end there is a hole drilled to catch some of the splashed lubricant and lead it to the bearing, and the tappets are spirally grooved so that they carry oil onto the entire surface of the chambers in which they work, making for quiet operation. On the left of the crankcase there is a breather, which is internally baffled so that any spray from the crankcase will not get out to collect on the outside of the engine, and there is also a float gage connecting with an indicator hand that plays over a dial mounted on the left side of the crankcase to inform the driver how much oil he has left.

In common with practically all installations now, the start-



Left side of the engine of the Buick four, showing the arrangement of intake and exhaust manifolds



Right side of Buick four engine, showing mounting of starting and lighting units and ignition distributer

The new Buick four has a wide door with plenty of room in the driver's compartment. The instrument board is neat and simple

ing motor meshes with teeth in the flywheel rim, pressing the pedal meshing the armature shaft gears with these teeth. The ignition distributer sets vertically on the front of the electrical unit, and is driven by spiral gear connection with the motor-generator shaft. Mounted on top of the motor-generator case is the ignition coil, and as the spark plugs enter the cylinders on the same side of the engine, there is a minimum of wiring from distributer to plugs, etc. These and other wires are inclosed within metal flexible conduit, a precaution against trouble that cannot be too highly recommended.

There is a leather-faced cone clutch on this car which is similar in design to that employed in other models. The cone itself is a pressing, and there are three springs placed at equal distances apart to hold the unit in engagement. There are also small springs inserted at intervals under the leather to force it out and produce a soft action. The clutch assembly includes two ball thrust bearings, the forward one taking the thrust from the engagement springs and the rear providing for the thrust occasioned by disengagement of the cone. The shaft on which the cone slides has six splines, and each of the engagement springs is provided with an adjusting nut which makes it a simple matter to give the proper tension, especially since the clutch can be reached from below the bell housing without the removal of any parts.

Chrome-nickel steel gears are used in the gearset, these having teeth of stub form so as to resist any suddenly imposed shocks. The bearing equipment for this assembly consists of a roller bearing for the clutch gear, a double-row ball bearing for the square shaft, and plain bearings with bronze bushings for the countershaft.

Ball Joint Torque Tube

The drive is taken through a single universal joint just back of the gearset, this being of large proportions and fully inclosed. The propeller shaft is also completely housed within a torsion tube that attaches to a large ball-and-socket joint on the rear of the gearcase, and terminates at its rear end in a flanged member that bolts to the front of the differential housing. Thus the torque is taken through the shaft housing and the ball joint at the front end, while the drive is through the rear springs.

Of three-quarter floating type, the axle is a compact unit designed so that all the car weight is carried on the axle tubes, with no supporting strain on the driveshafts. These are mounted on spiral roller bearings at both wheel and differential ends, with a ball thrust bearing also fitted at either side of the differential. The gears are of the bevel type, and the ring gear has fifty-three teeth to thirteen on the pinion, giving a ratio slightly over 4 to 1, thus allowing the motor plenty of chance to drive the vehicle with all the flexibility that should be desired.

In the rear spring arrangement, Buick deviates from that of the little six, which has cantilever suspension. On the new four the springs are semi-elliptic, long and flat. The dimensions are 48 in. by 2 in. wide, and the mounting is somewhat unusual in that they are not directly below the frame rails, but bracketed so that they run outside the frame. This was done principally because the frame tapers straight from the back to the front, and if the springs were placed under the rails they would also be at an angle, and this might have introduced an undesirable bending moment. As the frame is narrower at the front mounting than at the rear, the brackets at the front are simply brought out farther to allow the springs to parallel the wheels. At the rear the frame members bend down sufficiently so that the springs are mounted almost flat and this, in connection with their length, makes for easy riding, since the spring action tends to both sides of the horizontal, with dampening effect upon shocks. The front pair are also quite long, measuring 30 in. and being of the same width as the rear.

Tapering the frame from back to front is also new to Buick design, but is becoming very popular with modern car designs. It allows a short turning radius, and at the same time gives excellent support for the tapering body along its entire length. To assist the side members there are four strong cross pieces, each anchored with the aid of gusset plates.

The popular sloping lines and smooth exterior, with hood blending into the cowl, are given the car, with sufficient rake to the steering wheel to give a good appearance. Attention has also been paid to the matter of leg room in the drive seat, and almost any type of person ought to find comfort in driving the car. Equipment includes all the fittings looked for by the car purchaser of to-day, among which might be mentioned the adjustable windshield, the one-man top, the electric horn, the speedometer, the extra demountable rim and tire carrier at the rear of the frame.

Little Six Unchanged

Brought out over a year ago, the little six that is to be the new four's running mate for the coming year, really requires no lengthy description here. It is known as model D-44 as a roadster, and with that body sells for $985. The touring car on the same chassis is called model D-45, and the price is $1,020. Briefly, the specifications, which are practically the same as they have been since the car was introduced, are 3¼ by 4½ in. engine, developing 45 hp.; Delco ignition, starting and lighting; circulating splash lubrication; pump cooling; cone clutch and three-speed gearset; 34 by 4 tires and wheelbase of 115 in.

—

Dallas—$25,000,000 Distributing Center

DALLAS, TEX., did $25,000,000 worth of automobile business in 1915. In the city 178 buildings are exclusively occupied by the automobile industry. There are 108 wholesale and retail motor vehicle and accessory concerns located there. There are also seventy top, body and repair concerns doing business. More than 2600 employees are directly dependent upon this industry. It is estimated that these employees draw annually in salaries the amount of $28,000,000.

Such a business could not be produced if Dallas and the surrounding territory did not justify it. The State of Texas produces about one-fourth of the world's cotton crop and 60 per cent of this crop is financed at Dallas. That is the principal inducement that secured for Dallas the Federal Reserve Bank and which has caused the automobile concerns of the United States to center their Southern business at this city. Within a 100-mile circle around Dallas farm products annually are valued at $450,000,000, which is based upon figures recently obtained through census work.

There are 2500 financially rated business houses in Dallas, more than 400 factories and 275 wholesalers. One-fourth of the $400,000,000 worth of bank resources of Texas are held by Dallas banks. The average per capita wealth of the farmers within 100 miles is $7,500.

Marion-Handley in Two Models

Small Six at $1,185 and Large Car at $1,385 Comprise the Line—Several Body Styles

TWO sixes will make up the line of the Mutual Motors Co., Jackson, Mich., for 1917. These cars are sold under the name of the Marion-Handley, taking the name from J. I. Handley, president of the company. The sixes are in two sizes, known as the 6-40 and the 6-60, and the two cars possess great similarity of design.

In picking out the features of the Marion-Handley line, probably the outstanding point is the lightness in ratio to power. The smaller car has about 1 hp. for each 60 lb. weight and the larger car weighs about 58 lb. per horsepower. Throughout, both cars will be seen to follow very closely the up-to-date practice of high-speed engine with light semi-flexible frame construction, giving the characteristics demanded in the way of quick acceleration and economical performance.

45 Hp. at 2000 R.P.M.

The 6-40, the smaller of the two cars, has a high-speed unit power plant, with the 3⅛ by 5-in. cylinders cast in a single block. The engine is L-head shape, has a displacement of 230.1 cu. in., and develops, according to dynamometer tests by the factory, 45 hp. at 2000 r.p.m. The upper half of the crankcase is cast integrally with the cylinders and the lower part is pressed steel, being merely used as a housing and an oil retainer. Its capacity in the latter respect is approximately 1½ gal. This part of the crankcase is detachable in the customary manner to permit of the adjustment of the connecting-rod and main bearings.

Three rings are used on the cast-iron pistons, which are 3¼ in. in length. I-beam connecting-rods are used and both the upper and lower rod bearings are 2 in. diameter by 1⅞ in. long. The crankshaft is also 2 in. in diameter and is supported upon three main bearings, the front being 2¾ in. long, the center, 2¾ in., and the rear, 3⅛ in. These bearings are lubricated by a direct feed from the oil pump, thus maintaining a supply of lubricant to the crankshaft under pressure. The remaining bearings are taken care of by splash, and the timing gears are lubricated by overflow from the front main bearings. The crankshaft gear of the timing set runs continually in a well of oil. This permits the lubricant to be carried by the gear teeth over the surfaces of the entire timing set, thereby maintaining an oil film between the teeth of the gears at all times. The pump used in connection with this system is a plunger, operated by an eccentric on the camshaft and is self-priming because it is located in the oil reservoir in such a position that the last remnants of oil are sure to drain to the pump. A relief valve is provided to regulate the maximum pressure on the oil system.

Quiet-Running Gears

One of the points which has been given attention is the matter of quietness in the valve driving system, the cam gear being of Fabroil, which is a compressed cloth produced by the General Electric Co. and has the advantage of being non-resonant. This gear has a face width of 1 3/16 in., with 10 pitch helically-cut teeth. The camshaft is carried on die-cast nickel babbitt bearings. There are three bearings for the camshaft, two being of the material mentioned, while the third is an S. K. F. ball thrust, used at the rear end of the camshaft to take the thrust loads as well as the radial, in any direction.

A special alloy steel which the manufacturers claim to have many of the characteristics of cast iron is used for the valves. They are 1 3/16 in. diameter and have a lift of 5/16 in. One of the main points in which the alloy steel resembles cast iron in the valve is that it can be ground to a perfect seat. At the same time, owing to the composition of the metal, the molecular structure is much closer and the valves have a long life without as great chances of pitting.

Electricity All Westinghouse

Cooling is by a centrifugal water pump which is driven off the timing gears and is located on the valve side of the engine, in the same line as the electric generator. In connection with the cooling system there is a two-blade aeroplane type of fan of pressed steel which runs on ball bearings and

is fitted with a rocker arm adjustment for belt tightness. The radiator is a hexagonal honeycomb type having a capacity of 4 gal. and it is mounted by two bolts on the front cross member. There is also another unusual feature in the shape of a detachable case which is of considerable assistance in the matter of making repairs.

Electrically the entire equipment is Westinghouse. There is a Westinghouse generator which weighs about 16 lb. including the automatic regulating means. The latter is of the voltage type and is such that the charging rate varies with the condition of the battery. When the battery is nearly exhausted, it is charged at a high rate, while, when fully charged, the charging rate is reduced. In addition, the usual magnetic cut-out switch is incorporated so that when the charging rate falls too low, the battery is automatically cut off, thereby preventing a reversed current flow. The battery as well as the entire system operates at 6 volts and the capacity is 80 amp.-hr. An ammeter is located on the instrument board.

Ignition is also taken care of by the Westinghouse unit, the distributer being mounted on the generator, and the same unit contains the breaker box, spark coil and condenser. These units are easy to reach for inspection, the breaker box being inclosed within a collar which can be slipped out of the way when it is necessary to inspect or adjust the points, and the distributer cap is removable, together with the spark plug leads.

Control of the ignition and lighting system is by means of a set of switches on the instrument board. The lighting system consists of the Westinghouse generator, switches, and a full set of lamps in connection with the 6-volt, 80-amp. storage battery. A single pair of headlights is used with double bulbs. The larger bulbs are 20 candlepower for road driving, with 6 candlepower for dimming. The tail light is mounted in the center of the tire carrier, and all these lamps together with the remainder of the electric equipment is wired on the single wire grounded return system. In this the chassis, frame and metal body form one circuit. The starting motor is entirely inclosed and is engaged with the flywheel gear by means of the Bendix screw pinion shift.

Large Surface in Clutch

A dry multiple-disk clutch is employed, having eleven disks lined with Multibestos. Of these, five are driving and six are driven disks. They are 8 in. diameter and made of saw steel with an annular bearing for clutch release, this bearing being lubricated by the oil from the gearset which enters the clutch by means of grooves cut in the clutch shaft. An adjustment is provided on the clutch release pedal to take up any wear or lost motion that may develop in the clutch release bearing. This is done in order that the full throw of the clutch pedal is provided at all times, thus insuring the full disengagement of the clutch.

A Three-Speed Gearbox

A conventional three-speed gearbox of compact design is employed to transmit the drive from the clutch to the rear axle. The box is mounted integrally with the motor as a unit power plant and the entire construction is kept rigid by short shafts of nickel steel. The gears in the gearset have a face width of ¾ in., and the diameter of the countershaft is 1 5/16 in. with a 1½ in. main shaft. The splines are cut to a depth of ⅛ in. The bearing mounting is made up of four annular ball bearings arranged for end play adjustment, and the reverse idler gear is mounted on a plain bronze bearing. The gear reductions in the gearbox itself are 2½, 1 7/10, and 1 to 1, with reverse of 3.4 to 1. Final reduction is 4 5/12 to 1 at the rear axle.

Hotchkiss Drive Used

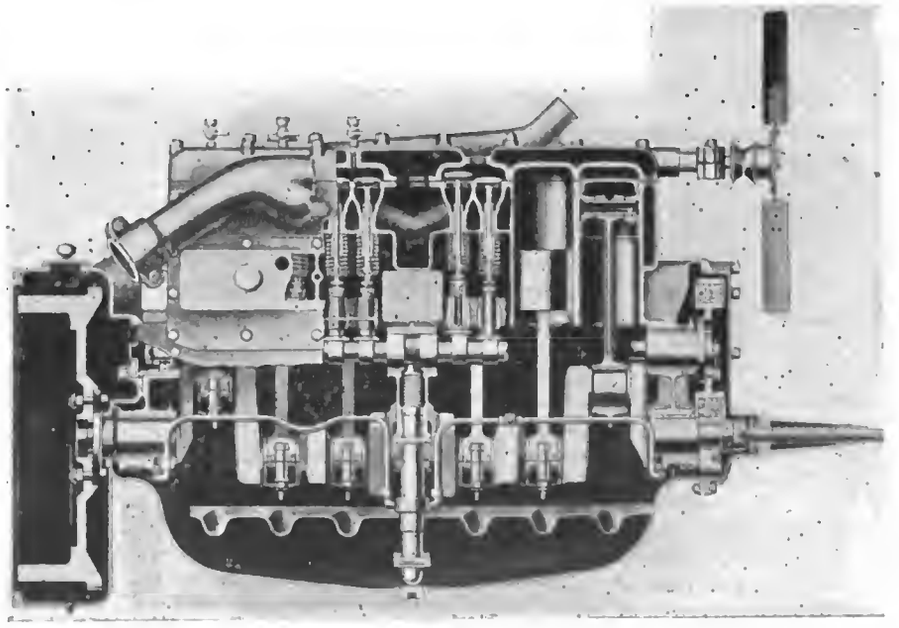
Both the drive and torque are taken by the rear springs, eliminating both torsion tubes and torque rods. A reduction of weight is further secured by the use of a tubular propeller shaft 1½ in. diameter with 5/32 in. walls. The shaft is equipped with two double ball and socket universal joints and has a fore and aft travel of 2 in. The universal cup, ball and trunnion pins are hardened and ground and packed in grease.

Robust Axle Proportions

Floating construction is used in the rear axle. This is equipped with a Brown-Lipe spiral bevel gear and is provided with a set of Hyatt high-duty roller bearings with adjustable ball bearings for side thrust. The pinion shaft is carried on two annular ball bearings which are adjustable, allowing take-up for wear or play on the pinion shaft. The drive pinion can also be adjusted in regard to the mesh with the spiral bevel ring gear. Chrome-nickel steel is used for the drive shafts and they are 1¼ in. diameter. The entire differential may be removed by taking off the inspection plate over the differential.

Two sets of brakes are used with the drums on the rear wheels as usual. The service brakes are contracting and emergency expanding, both being provided with two adjustments, one on the brake rod ends and the other attached to the brake bands. The drums are 14 in. diameter and have a face width of 2 in.

Elliott type front axles are used of I-beam section, drop forged without welds, the spring seats being integral. The steering knuckle and axle ends are fitted with bushings while the knuckle pins are hardened and ground with a trap oiler at the top of the bolt to insure lubrication. The drive lengths are designed to permit a minimum turning radius and the car is able to turn about in a 25 ft. circle. Both front and rear wheels are of heavy hickory, with twelve 1½ in. spokes. The front wheels are carried on Gurney annular ball bear-



Section through the Marion-Handley block-cast six-cylinder engine. Note the large bearings. The cam gear is of Fabroil and special alloy steel is used for the valves

At the left is illustrated the six-cylinder, seven-passenger Marion-Handley 6-40 touring car, which sells for $1,185. The body lines are smooth and the windshield slants rakishly

At the right is the Marion-Handley 6-40 as a four-passenger roadster listed at $1,185. The seating arrangement is attractive and the seats are of comfortable dimensions

ings of the "100 per cent thrust" type. A full equipment of Firestone demountable rims is furnished, adapted to 32 by 4 in. straight side tires, and non-skids are used on the rear wheels. The wheelbase of this model is 120 in.

Equipment Is Complete

In equipment the car is complete, the 16-gal. round tank being located at the rear with Stewart-Warner vacuum feed. The body is a roomy seven-passenger design of heavy gage sheet steel, with pressed steel cowl and concealed hinges. There is also a four-passenger roadster of up-to-date construction, in which the driver's seat is set forward 15 in. from the double passenger seat and a fourth or auxiliary seat is carried folded into the dash. The standard equipment also includes a Chase leather one-man top with Collins quick detachable side curtains which swing open with the door. The windshield is slanting and is provided with clear vision features. The body finish is in dark wine color with black fenders and splash aprons.

6-60 Almost Identical Design

Of similar design is the 6-60. This is equipped with a 300 cu. in. motor, having its 3½ by 5¼ in. cylinders cast in a single block. This is also a conventional L-head design, and, according to the manufacturers, develops 50 hp. at approximately 1900 r.p.m. The crankcase is cast separately of aluminum and is equipped with a pressed steel oil pan. All the bearings are supported in the crankcase and are accessible by removing the pan. The inclosed valves are 1 11/16 in. diameter with 3/16 in. lift. They are operated by a single camshaft and both inlet and exhaust valves are interchangeable and have nickel steel heads electrically welded with carbon steel stems. The ends of all the valve stems are hardened to insure against wear from tappet action. Pistons and cylinders are both made from the same grade of reverberatory furnace iron, with a piston length of 3¾ in., fitted with three diagonally split concentric rings 3/16 in. wide. The piston pins are of annealed special steel tubing hardened and ground, with the pin held stationary in the piston bosses. The bearing surface is given by a bronze bushing pressed into the upper end of the connecting-rod.

An integrally-forged low carbon steel camshaft is used, carried on three bearings of white bronze. The dimensions of these cam bearings are: 2 17/64 by 1½, 2¼ by 1⅛, and 2 7/32 by 1¾, respectively, from front to rear. The crankshaft is also carried on two bearings and is of special crankshaft steel, heat treated to give a tensile strength of 90,000 lb. to the sq. in. The main bearing dimensions from front to rear are: 2 3/16 by 2 23/32, 2 7/32 by 2⅜, and the rear or flywheel bearing, is 2¾ by 3. All the bearings are reamed to a fit on expansion arbors and then finished with a slow-running spiral cut power burnisher which is stated to give a bearing surface of over 98 per cent.

Lubrication is by force feed and splash, actuated by a horizontal pump driven by an eccentric from the camshaft. This forces oil through copper tubes direct to the timing gears and the main crank and camshaft bearings. The remaining bearings are taken care of by splash.

Throughout the remainder of the chassis, the design of the 6-60 is quite similar to that of the 6-40, with the parts necessarily stronger and larger to take care of the higher power and greater weight. The Hotchkiss drive is used but the reductions are different, the final gear ratio being 4 1/3 to 1, and the wheelbase is also greater, being 125 in., while the tires are 33 by 4½.

The body equipment includes an up-to-date seven-passenger car and a four-passenger roadster. This car is fully equipped with accessories, having a Stewart-Warner vacuum feed, Chase top, Collins curtains, full set of instruments and tools, extra Firestone rim, etc. Prices are $1,185 for the 6-40 and $1,385 for the 6-60, in either roadster or touring form.

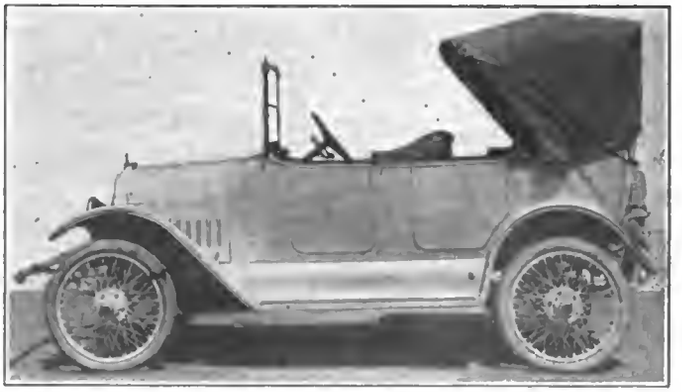
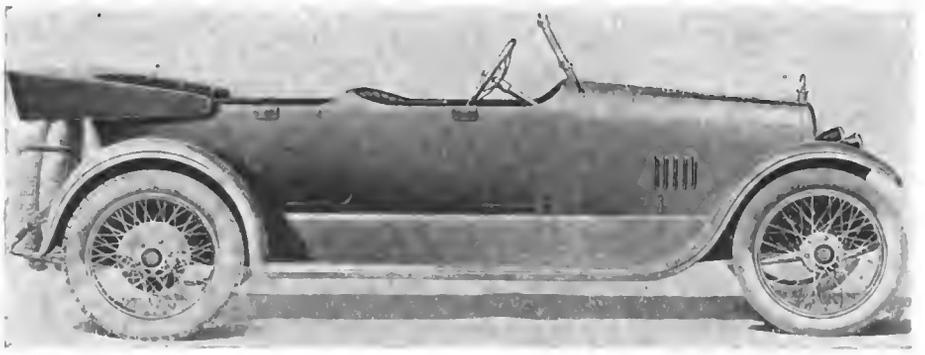
Special Maxwell with Victoria Top



Above is illustrated a recent creation by Harry J. DeBear, manager of the New York branch of the Maxwell Motor Sales Corp. It is a Maxwell touring car painted a special light blue and fitted with white wire wheels, Victoria top and slip covers to match. The car sells for $950 complete, f.o.b. New York City

Blended Ideals in Jordan



Jordan four-passenger sporting model with 127-in. wheelbase and listing at $1,750

New Six Possesses Many Points of Distinction —Chassis and Body Well Coordinated— High Finish Combines with Sound Conventional Design

THERE are some who consider it difficult to produce a really distinctive automobile from standardized parts and it is, in fact, not easy. While anyone can build a sound car from reliable components, it remains for the few to effect the best combinations, and many a body is kept from being really excellent by a few small blemishes of design or finish which can only be eliminated by painstaking care. In the evolution of the Jordan this truth has been realized, with the result that the car has not only a character of its own, but a pronounced distinctiveness apparent at the first glance and intensified by a close examination.

Every Need Considered

In starting to produce the Jordan, consideration was given to almost every sort of ideal. The requirements of the world and his wife were analyzed, argued over, tabulated and, finally, coordinated. Before any work was done on the car a list of features was prepared stating in detail every point which had to receive consideration. It was the aim of the Jordan Motor Car Co., Cleveland, Ohio, to produce a machine which lacked nothing, in which the mechanical arrangement was above criticism, the body lines just at the right pitch of fashion and the finish of a custom-built quality. The precise extent of the success achieved may be judged by the illustrations and by the description of the car which follows, but it may be summed up by saying that the Jordan immediately appeals both to the man with long automobile experience and to the individual with none.

High-Grade Parts in Chassis

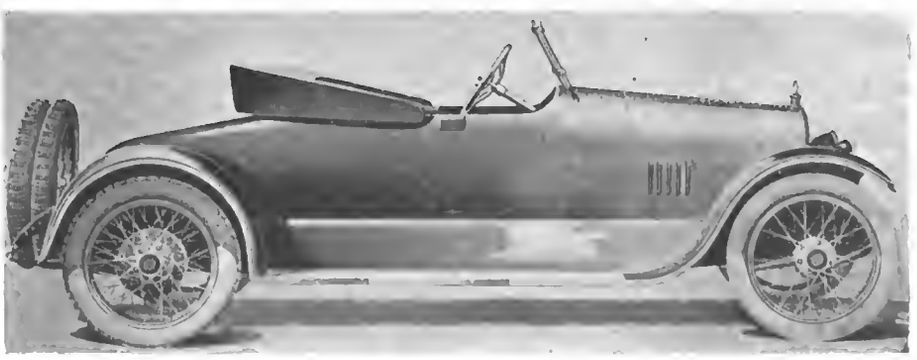
Not a unit of the chassis is untried and the specification is quite conventional, its noteworthy feature being that each component ranks high among its kind, and is the best model built by the parts specialist in question where there is any choice. Motive power is supplied by a six-cylinder Continental engine 3½ by 5¼ in., this being the aluminum crankcase type and the power plant is completed by a Brown-Lipe gearset and a Brown-Lipe multiple dry disk clutch. As to the engine accessories these include Bosch magnetic ignition, Bijur two-unit lighting and starting and a Stromberg carbureter.

As can be seen from the illustrations, the hood has plenty of width and depth, the result being that the mechanical inhabitants of the bonnet are no more cramped than the human occupants of the car body. Every essential is accessible readily.

Both front and rear axles are Timken products, the drive, of course, being by spiral bevel, and the frame is of deep section to give rigidity and enable the firmly-built body to keep free from looseness after long use.

The bodily comfort of the passengers has been studied with especial care, and a short trial of the car enables it to be stated with conviction that the ease of riding is very much above the average. It is not too much to say that very few cars indeed ride as well as does the Jordan. This desirable quality is attributable partly to the springs and partly to a special feature of the upholstery. Taking the former first, they are half-elliptic front and rear, the back springs being 59 in. long and almost perfectly flat when the load is on them. They run beneath the axle and the rear end of the frame is brought well down in a sweeping curve to carry the shackles. This low hanging allows the frame to be brought fairly close to the ground, and the flatness of the springs gives lateral strength to resist rolling action, of which there is remarkably little.

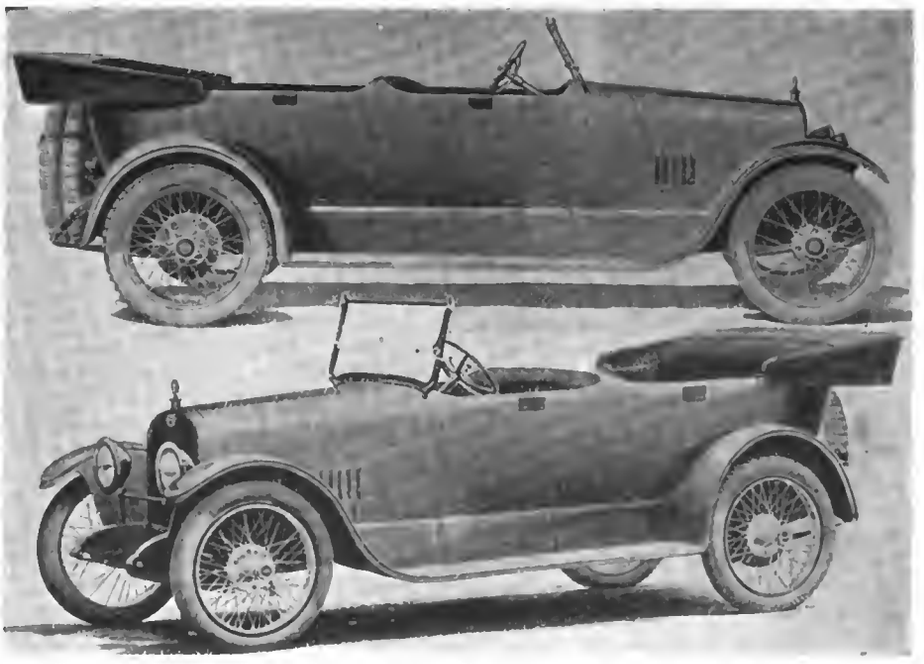
In the seat cushions the Marshall spring is used. This has been developed for high grade furniture and now makes its first appearance on an automobile. The usual nucleus of a cushion is a couple of wire frames separated by a number of large springs coiled to a big diameter. If one of these springs gives way under the stress of use, there at once appears a hollow in the cushion, because each spring supports a large area of leather. In the Marshall construction the springs are much smaller and a great number of them are used. Each little coil is sewn up in a canvas container and scores of the springs are bunched together. A little padding then goes over the top and then the leather, so that every square inch of the cushion has individual support. Owing to the number of springs used each one can be soft, so that the effect is equivalent to a pneumatic cushion, though with less bounce. Another thing that makes for comfort is the shape of the seats, for this has been worked out so that the height and depth of each and the angle of the back is just



The roadster model sells for $1,650, the same price as the seven-passenger touring car

right. The rear seat suits the woman of average stature, the front seat the average man, and to allow for variations in the stature of the driver, the pedals are adjustable over a wide range. It is specially noticeable in the front compartment that the wheel and the door are in such proportion that any man can get into the driving seat from the left side without any difficulty, even when wearing a heavy coat.

Speaking of the driver's comfort leads naturally to a comment on the placing of the gear shifting and brake levers. These are within easy reach without stooping or leaning forward, and the two are far enough apart to make the chance of a mistake extremely slight. The gear lever is carefully fitted so that it moves easily, and the clutch needs only a light spring. Also the long flat rear springs and the Hotchkiss drive cause very little variation in the relative positions of the brake parts, so that there is little lost motion on the service brake pedal and a fairly light pressure exercises great stopping power. The frame is well narrowed in front so that there is a good turning lock despite the 127-in. wheelbase.

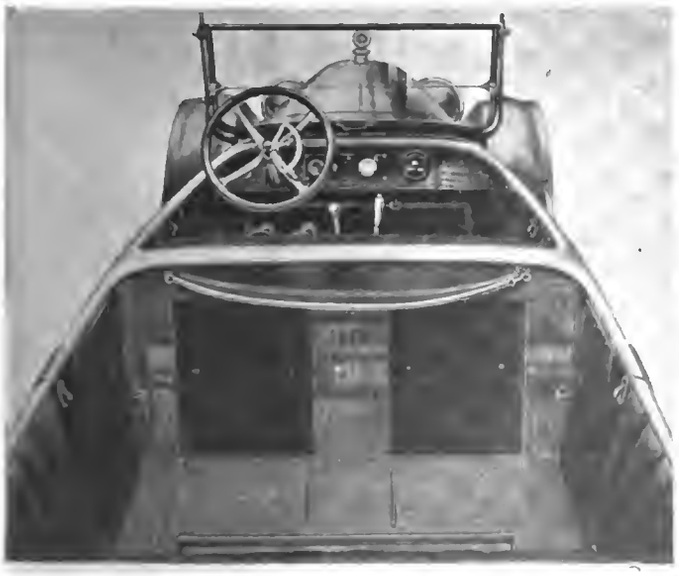


Two views of the Jordan seven-passenger touring car, which sells for $1,650

High Finish in Body

Returning to the body once more, it may be mentioned that the upholstery is all of the best hand-buffed leather, a thick yielding quality with the dull gloss that contrasts best with the highly polished mahogany work on other parts. The back of the front seat contains the folding seats which drop into compartments and are covered by leather curtains or flaps. All the rest of the seat back is light mahogany and is a regular custom style of job made of many pieces with matching grain. The center cowl effect is obtained with the minimum sacrifice of space the front corner of the rear door being cut into the edge of the center strip.

Across the back of the front seat is stretched a robe strap with a snap fastening, this being of brown leather to match the mahogany; there is a thick, soft tonneau carpet and a substantial foot-rest. These petty details of body equipment are mentioned so particularly because each one contributes to the completeness and very real luxury of the whole. It is in the choice of such detail that the Jordan has striven to raise itself into the custom-built class. The sloping windshield for example, is not just a windshield. Its proportions suit the car, its hinges work smoothly and the top sockets snap readily into place.



Plan view of the Jordan, showing smooth lines

In order to maintain the standard set the Jordan company is not planning a big output, but will use a very rigid inspection. In the main floor of the plant there is a special spot upon which each car has got to stand before it goes to the shipping bay. After every detail has had its individual inspection, after the car is reported as O.K. it has to undergo a final, painstaking checking up to insure that nothing has been overlooked.

Touring, Roadster and Sporting Models

There are three models listed, the first being a seven-passenger car and this will be ready for delivery starting Aug. 1. This car normally has wood wheels and sells for $1,650 so equipped, wire wheels costing an extra $100. Next there is to be a sporting model four-seated car on the same 127-in. wheelbase but lower built and this will have wire wheels and will cost $1,750. Finally the range is completed by a roadster costing the same as the seven-passenger model.

All types are fitted with Firestone rims and have 35 by 4½-in. tires, those on the rear wheels being of non-skid pattern while a Moto-Meter is included among the equipment.

Radiator Cap Fittings

A SCREW thread is not the best thing to use for attaching a radiator cap. It is almost universal because it is the simplest form of attachment and it is cheap, but it is not nearly so convenient as a snap attachment like, for instance, the Packard design.

The cap should be held on so that it cannot be dropped and lost and there are many ways of making cheap, secure caps without a screw thread. Even when a screw is used there seems no reason why a short length of chain should not be fixed to the inside of the cap and to some interior place on the radiator, so that the cap, when unscrewed, would still be attached to the car. A chain might rattle perhaps, but if it did a bit of plaited fishing line would serve the purpose almost as well and would last for years.

Conveyor System Aids Big Production

Progressive Assembly Methods Cut Time and Labor—Three Classes of Chain Assembly—Group Assembly Also Used With Success—Manufacture by Time Table

By Leslie V. Spencer

HOW has it been possible for car manufacturers to produce nearly as many machines during the first half of 1916 as were built in the entire previous year, without adding to their factory areas or equipment anywhere near in proportion to the increase in production? The answer is that most of the large producers have adopted some form of the moving conveyor assembly scheme. This is the last word in automobile production, and is a great step forward, putting the building of motor vehicles on the same plane with the scientific manufacture of any one of hundreds of articles of commerce in the up-to-date plants of to-day.

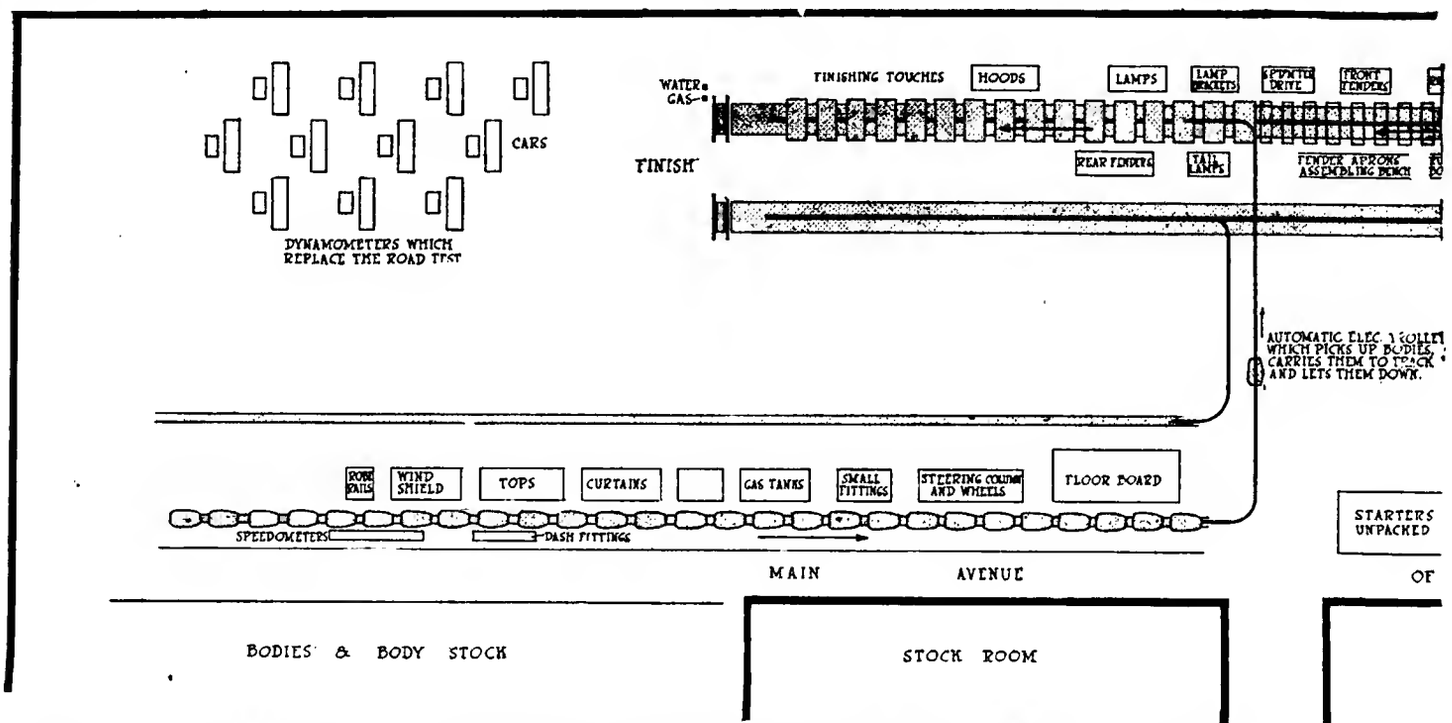
Few of us stop to think, in the present day of million-car-a-year output that only a few years ago it was an unheard of thing for any factory to turn out as many as 500 or even 300 cars a day. In 1912 Ford, always the leader in quantity output, built 78,440 cars, a daily average of about 260 cars for a 300-day year. Now we think nothing of Ford's 2000-a-day output, Overland's 1000-a-day schedule, nor of the large number of plants making well over 200 daily, such as Buick, Maxwell, Studebaker, Chevrolet and Dodge.

In all of these large-producing plants some form of the moving conveyor assembly arrangement is applied, and also in many of the plants that are very large producers, though not as yet in the 200-a-day class. This simply indicates that the industry recognizes the economy and large output possibilities of the moving chain method, and has taken it up almost universally where it is desired to build cars in any sort of quantity. In fact, the moving assembly is proving a big saving in cases where the output is as low as fifty cars a day.

Although there are three types of chain assembly, each best adaptable to certain classes and kinds of cars, the general scheme of all is the same, in that the chassis starts as a bare frame, and as it moves past the various parts, these are fitted to it by men who have specialized in the mounting of this one thing and know just how to go about it for quickest application. At the beginning of the assembly line are the piles of axles, driveshafts, springs, brake rods and other smaller parts. Each is far enough removed from the next so that there is time for the placing of one before the next goes on, unless they are parts whose application does not interfere, in which case two gangs, or even three may be working on the moving frame at one time. As the chassis moves along, other parts are added, until at the other end the machine has grown into a complete automobile ready for the road. In most cases, this moving scheme does not even except the fitting of the body—it is put in place just as any other part while the relentless chain moves steadily forward.

Three Classes of Chain Assembly

Chain assembly equipment may be divided into three classes, as stated, with respect to the method of carrying the car-in-the-making along. The Ford method is one way. In this case there are two iron rails on which the axles rest, and these slide along as the chain moves, requiring no truck for carrying the chassis even though it has no wheels of its own as yet on which it could move. Others of the big producers utilize the method of mounting the frame on a conveyor truck which is the car's constant companion until it reaches the finish end of the chain, a completed vehicle. In



Diagrammatic plan illustrating the layout of the Maxwell progressive system of manufacture and assembly which enables this plant to turn out in excess of 40,000 cars in 6 months

the third modification, the chassis is carried on a conveyor truck until it reaches the point where its wheels are attached. Then it finishes its growth on its own tires, being pulled along by a chain, however, with one of the wheels running in a guide groove to maintain proper alignment.

Obviously, each method has its advantages, and it would be incorrect to say that any one is better than the rest. The size and shape of the factory buildings, the type of car and the methods of assembly all have a bearing upon which equipment is used. If the building is long and narrow, pulling the cars end to end on their own wheels is allowable, because there is sufficient length to the conveyor to permit of this arrangement of the cars, but, where a larger number of vehicles are to be drawn along, they are carried on the conveyor trucks at right angles to the chain, affording a chain of given length a greater capacity than if the cars were end to end. At the same time, however, this adds somewhat to the width of the required space. Paige, Hudson, Overland, Studebaker, Dodge, Reo and Saxon are good examples of long and narrow plants that lend themselves to the end-to-end method on the car's own wheels, while the long and wide assembly building of the Maxwell company is admirably adapted to the type where the cars are side by side.

Aside from the room which the type of moving assembly in which the chassis is carried at least part way on its own wheels takes up, this method has the advantage of eliminating the conveyor trucks which are not only a big item of expense but add to the weight which the chain must pull, and hence to the necessary power. Besides, some scheme for returning the empty trucks back to the starting point must be devised, in most cases this problem being solved by the use of a tunnel under the conveyor, another chain pulling the empties back to the point where they are automatically returned to the assembly track, ready for reloading. However, most production men believe this to be the fastest method of progressive assembly, since it gives the conveyor the greatest capacity.

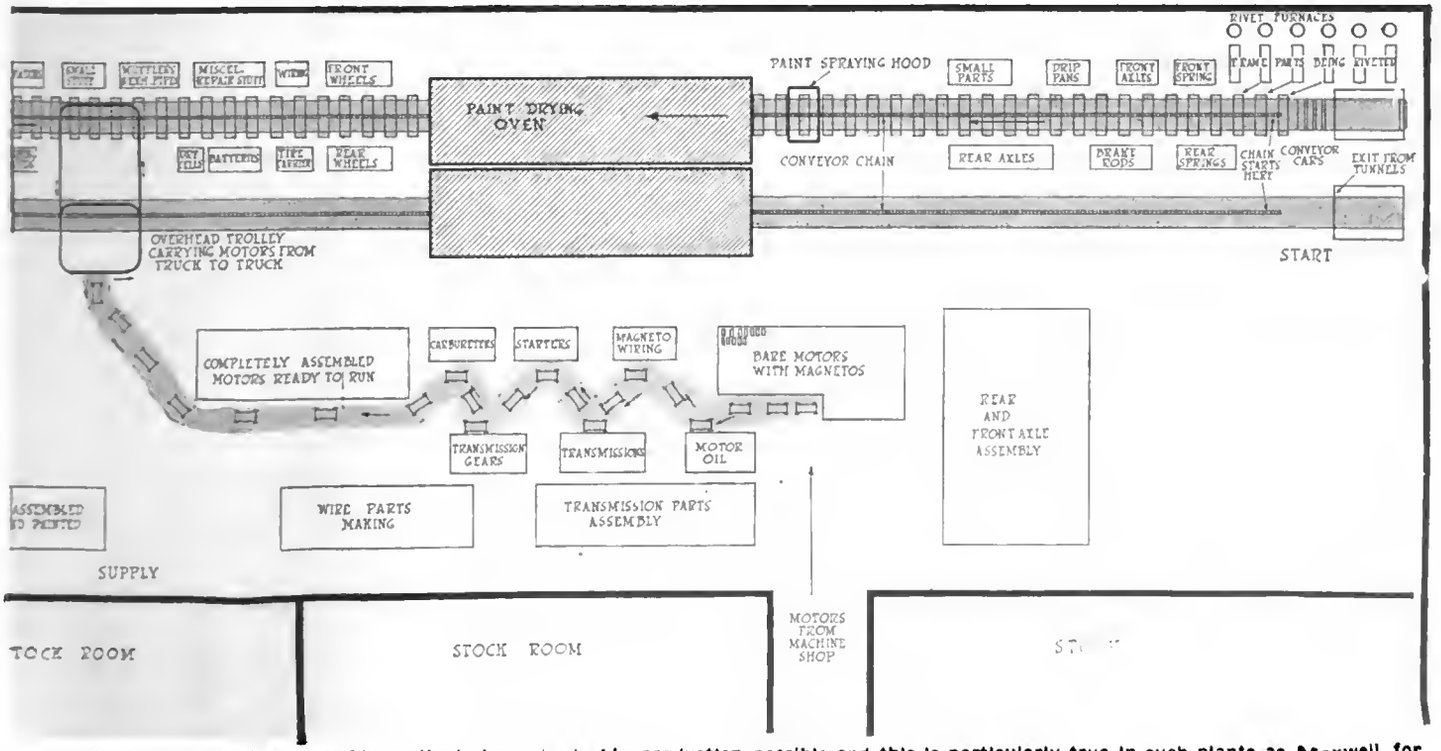
Some Have Group Assembly

There is another point for argument between these two types, this being as regards the convenience of working around the moving chassis. Those who have the end-to-end equipment believe that the workmen have more chance to get to all sides of the moving vehicle than would be the case if the chassis were carried at right angles to the chain. However, in the latter case, sufficient space is usually allowed between each chassis, so that the men have room enough to do their work.

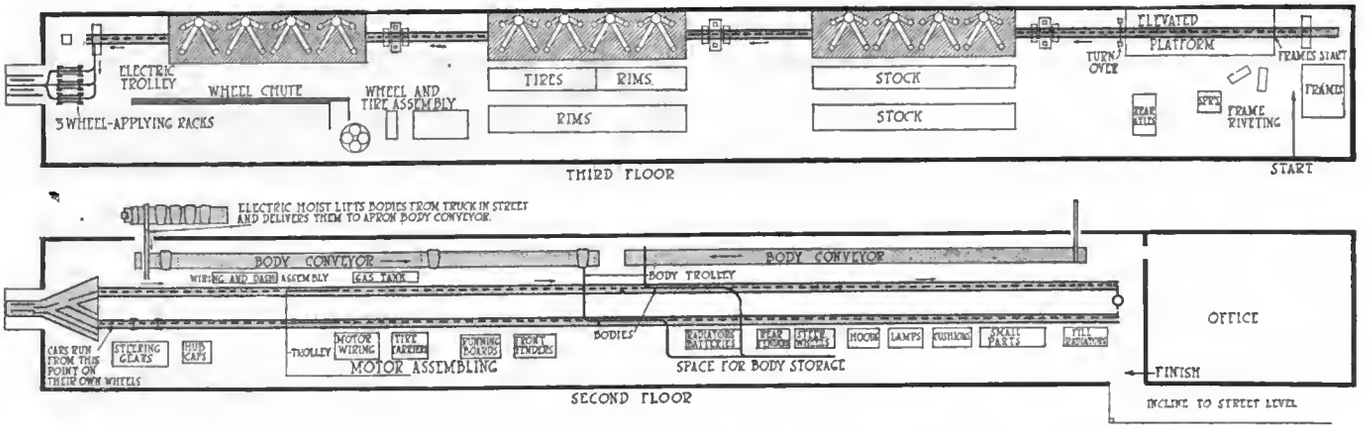
It might be well here to call attention to the fact that moving assembly of this kind is not favored by every large factory, such well-known plants as the Cadillac and Chalmers adhering to what might be termed group assembly. In this scheme crews advance the chassis step by step and each individual man is usually familiar with all of the operations required in that step. This is in contrast with the usual moving chain assembly proposition, because in the latter each man has a particular bolt to tighten on each chassis or a special part to put in place, and after he gets that one thing done, his responsibility, so far as that particular machine is concerned, is over. Where group assembly is employed, each man is familiar with all the operations that are necessary to carry the car one or more steps farther toward completion.

It is argued by those who favor this method that the men become more intelligent individuals and less like machines, and hence a better assembly is obtained. They also think that when a man finishes the particular thing he is doing he will help some other in his own crew to the end that the part or chassis, as the case may be, may be advanced to the next crew as quickly as possible. There are, of course, other arguments both ways, but the march of progress of car production seems to indicate that the trend is toward the more machine-like method of moving the chassis relentlessly.

Of course, the big advantage of moving chain assembly are that it greatly speeds up the production by absolutely regulating the output in accordance with the speed at which the chain moves. The factory production man in charge knows how many men it requires to put together a given number of cars when the chain runs at a given speed, and if the demands of the sales department are for a greater number of cars, he can positively guarantee to turn them out by running the chain faster and if necessary, increasing the number of assemblers, granted, of course, that he is not held up for lack of parts. There is a limit to the capacity of any chain equipment, but the method takes a great deal of



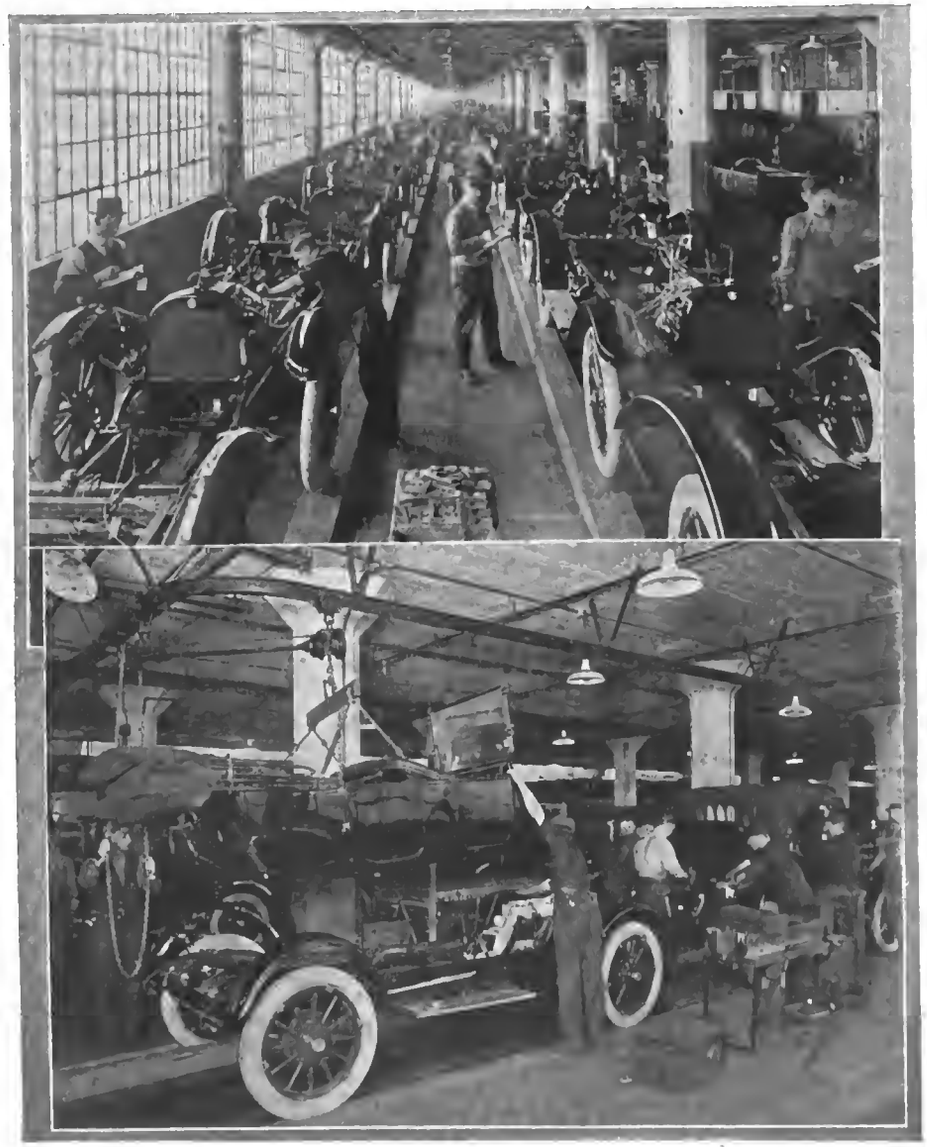
Modern progressive assembly methods have made big production possible and this is particularly true in such plants as Maxwell, for example, where the scheme diagramed above is used



Third and second floors in the Paige factory, where the chain system of assembly is employed

the uncertainty out of the production end of the business. As each man becomes more expert at doing his part, it has been found that the chains can be speeded up without materially increasing the number of men employed. The piecework system of paying the men is a big factor in increasing their efficiency, and hence the output.

Monorails play an important part in these modern assembly plants. All heavy parts are brought to the points where they are to meet the on-coming chassis by means of these overhead tracks, this applying to such units as the front and rear axles, engines and bodies. In some cases the work has been so far perfected that electric trolley systems are now installed which automatically convey the units from the stockroom or other point of supply, direct to the points where they are needed, over the moving chain, and hold them suspended ready for lowering into place with the least manual effort.



Men and methods in the Dodge plant which enable this concern to turn out more than 200 cars for every working day

In order that greatest general efficiency can be promoted, it is usually the practice to assemble as much to each unit as possible before it comes to the final chassis assembly, making it necessary to do the least number of operations on the moving embryonic car. Thus, the wheels come to the point where they are to be applied with the tires in place; bodies arrive with as much of the wiring on them as it is possible to place before they are attached to the frame; motors are possessed of all their equipment, with carbureter and ignition control rods waiting only to be connected to the steering gear to be entirely assembled, and so on. Several of the big plants even have machines for attaching the tires to the wheels, this being an example of how all parts of the manufacture are carried out with as much dispatch as is evidenced at the final assembly itself.

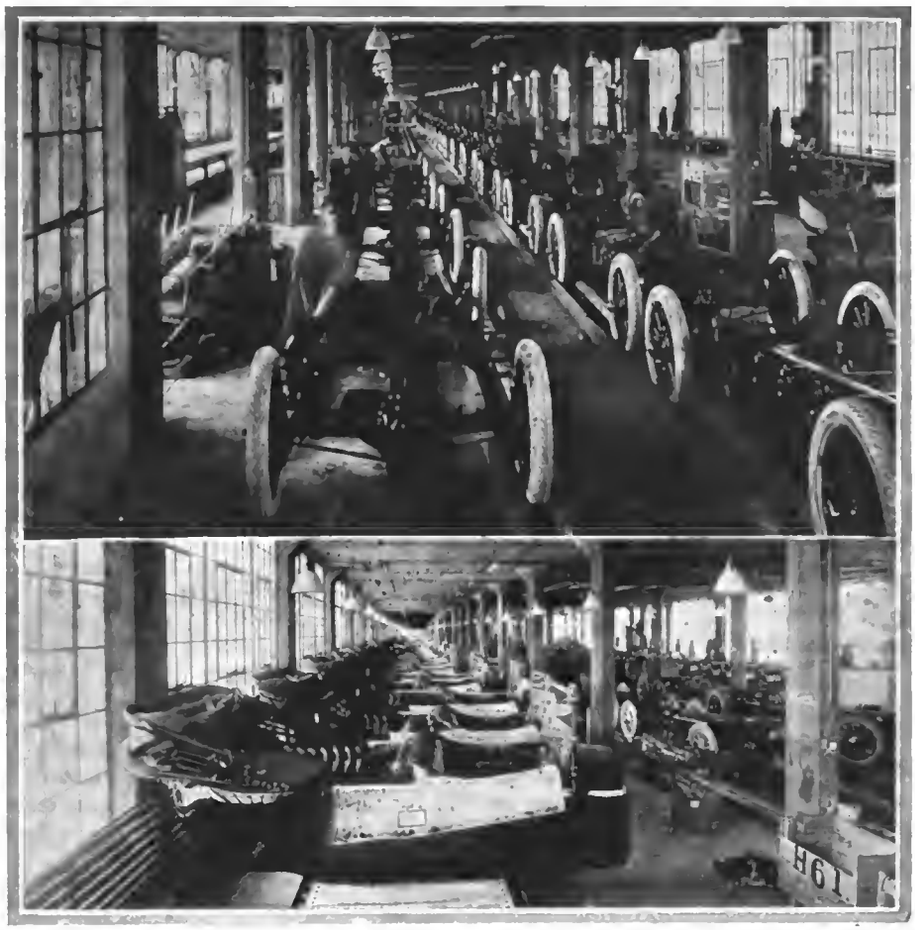
Where the scheme of carrying the car through its entire assembly on a conveyor truck is employed, great ingenuity has been displayed in devising means for quickly and almost automatically unloading the finished car from the truck onto its own wheels, to be driven to some other point under its own power for final test. Usually, when the conveyor truck gets to the unloading point, track, conveyor truck and automobile are all lowered sufficiently for the car's wheels to rest upon the floor, the truck that has been its companion up to this time dropping down, and automatically engaging the return chain that is to pull it back underneath the assembly chain to the starting point.

An advantage of the method where the wheels carry the chassis part of the way is that no mechanism for un-

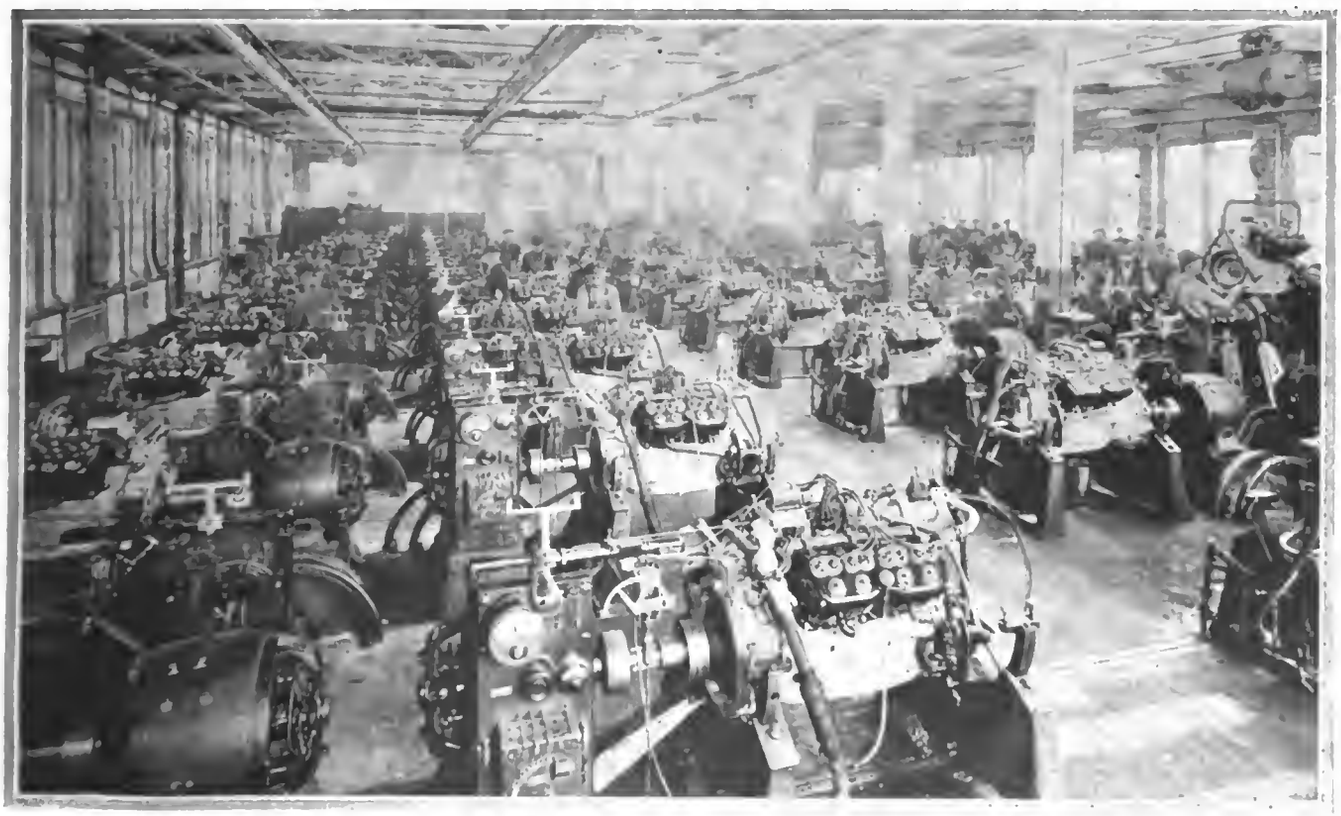
loading is necessary, but there must be means, however, for lifting the frame from its conveyor when the wheels are applied—usually an overhead hoist. Maxwell and Packard both have very good schemes for lowering the car onto its own wheels, the former lowering the whole thing to the floor level, whereas Packard runs the car onto an incline that engages the wheels while the conveyor truck drops below and out of the way. Paige might be mentioned as a good example of the method where the wheels are applied half way of the assembly journey and carry the car on to the end. An electric hoist picks the chassis, sans wheels, from the truck, lowers it to a wheel-attaching platform, and after these are in place, drops it through a chute to the floor below where the vehicle begins the last part of its journey on its own tires. Hudson utilizes cleverly a freight elevator for removing the car from the assembly truck. This does the work without damage.

Chassis-Painting Difficulties

Chassis painting presents some difficulties for the chain assembly. When the frame, axles, springs and other parts are put in place, they are minus paint, yet the chassis meets the body with its enamel baked on and dry. Thus the chassis is first painted and finished by inclosing a length, or sev-



Paige-Detroit chain system in which the body and chassis run along parallel lines on separate conveyor systems allowing of easy transference of bodies to chassis



In spite of big production schedules manufacturers are not neglecting to test every unit. Shown above is the dynamometer room of the Cadillac Motor Car Co.

Some of the 32,000 workmen which help to make the Ford production of 2000 cars a day a possibility

eral lengths, of the chain and track within a baking oven of sufficient length that the enamel, sprayed on just before the chassis enters this part of its journey, will be completely dry when the chassis emerges at the other end of the oven.

Drying Oven Takes Space

These drying ovens fill a great deal of the conveyor length, but they are proving a saving wherever used. In some cases there are several sections of oven between which are stationed men who spray the chassis ready for its next drying in the oven following. Packard has a very elaborate system of doing this, first applying the ground coat, then passing the chassis through a 120-ft. oven, following which a color varnish is sprayed on and then another oven 130 ft. long again dries the chassis as it moves along. Emerging from this heat, the chassis gets a clear varnish and is then conveyed on its assembly truck to a storage side track, where it waits usually about a day for complete drying before being placed on the final assembly chain. This, however, is one of the few plants where there is any wait between the time the frame first starts on the moving chain until the completed car comes off the opposite end.

Paige utilizes a 735-ft. conveyor on the top floor of its long main building exclusively for the assembly of the frame and axle parts and painting. Having added the axles, etc., the chassis gets its first priming coat in 2¼ min., and then consumes 1¾ hr. to pass through an oven 134 ft. long that is kept at a temperature of 180 deg. Still moving, it emerges from this first oven and the space between this and the next oven of equal length is traveled in 36 min., which is sufficient time at the speed at which the chassis is moving, to allow complete drying and spraying with the next coat for entrance into the second oven. These two ovens take care of the chassis paint and it is then ready for its wheels. Somewhat similar to this are the series of ovens, open spaces and spraying stations used by the Hudson company. Maxwell is an example of still another modification, the chassis receiving one thorough spraying coat and passing for a distance of 100 ft. through a single oven.

Speed of Conveyor Systems

To give some idea of the extent to which the moving chain assembly has been developed, the following data on systems in several of the well-known plants may be of interest.

Some Data on the Chain Conveyor Systems

PACKARD

Total length of moving chain, 1200 ft.
Speed of chain, 12 ft. per min.
Axles, motor and chassis paint, conveyor chain, total length, 792 ft.
Final assembly chain, 408 ft.
Capacity, final assembly chains, 40 cars at one time.

MAXWELL

250 cars in 9½ hr. per assembly track.
Length of conveyor, 800 ft.
Capacity at any one time, 100 cars.
Time for completing car from start to finish, 3 hr. 15 min.
Time for fitting a spring, 1½ min.
Fitting rear axle, 3 min.
Speed of chain, 40 in. per min.

PAIGE

Frame Conveyor

Speed, 18 in. per min.
Length of conveyor, 735 ft.
Load pulled by conveyor when full, approximately 75 tons.
Capacity at 18 in. per min., 150 complete cars in 10 hr.

Return Truck Conveyor

Speed, 20 ft. per min.
Length of conveyor, 760 ft.

Ovens

Three.
Length, 134 ft. each; width, 18 ft.; height, 6 ft.
Temperature, 180 deg. Fahrenheit.
Heated by steam.
Temperature can be raised or lowered to suit conditions of production.
Total chassis and final conveyor speed, 24 in. per min.

Double Body Conveyors

Speed, 10 ft. per min.
Length, 350 ft.

New Magneto Very Simple

No Wires on Armature—Aluminum Die Cast Parts Produce Light Weight Machine—No Carbon Brush

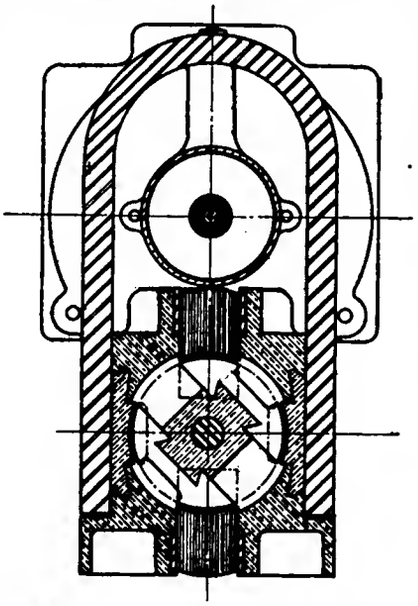
THERE are many different ways for making successful magneto machines and a new type just introduced by the Berkshire Magneto Co., Pittsfield, Mass., has a number of features differing from the ordinary.

Firstly, one of the principal claims made for this instrument is that while it gives a strong spark at low speeds and thus insures easy starting, the fierceness of the discharge increases at a lesser rate than the speed. It is, of course, possible to have too hot a spark. If the high speed discharge is very intense it has a destructive action on the points of the spark plug and the breaker points and puts an undue strain on the condenser and insulator.

Big Low-Speed Spark

Owing to the peculiar magnetic circuit of the Berkshire instrument it is claimed that the discharge current reaches one-half of its maximum amount at 50 r.p.m. while at 150 r.p.m. it has attained 80 per cent of the maximum intensity. This means that the spark produced at 150 r.p.m. is practically identical with the spark at 3000 r.p.m. or over.

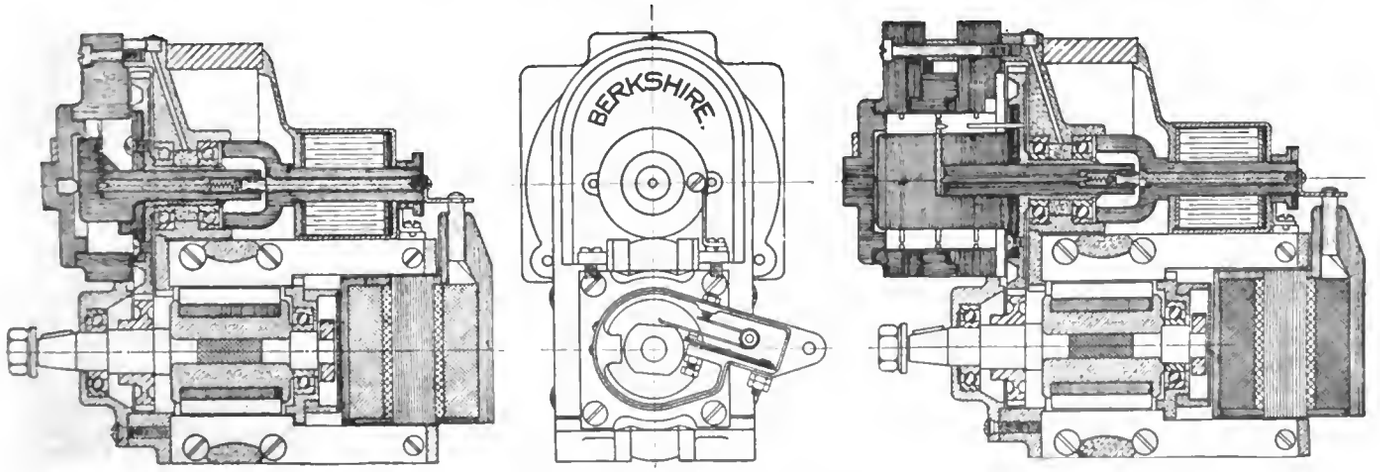
The reason for this action is not easy to explain, but some idea of the action may be obtained when it is stated that the magnetic circuit in the instrument is such that increasing magnetic flux caused by increasing speed meets with an automatic opposition. The action may be likened to that of the endeavor to force water through a length of pipe. The resistance to flow through a small pipe is such that above a certain speed the amount of extra pressure required to increase the flow is very great indeed. Another way of regarding it is to think of an electric condenser which can only hold a certain amount of electricity. With any condenser there is a limit of charge which cannot be exceeded. Similarly in the Berkshire magneto an increase in speed of 2000 per cent increases the flux through the armature by only 25 per cent.



Section of Berkshire magneto showing unwound armature construction. The two main pole pieces seen right and left, and the laminated, supplementary poles top and bottom are locked together by being cast integral with aluminum alloy

In the Berkshire magnetos there are no windings, either low tension or high tension, on the armature. In fact, the only revolving member which carries electric current is the internal portion of the distributer. The horseshoe magnet has two poles and two supplementary poles of soft iron are placed in the mouth of the horseshoe being magnetically insulated by aluminum. In the transverse section drawing of the instrument it can be seen that there are four deep grooves in the armature which means that the four iron portions of the armature correspond to the pair of main poles and the pair of supplementary poles in the field magnet. The iron parts of the armature are held together and magnetically insulated also by aluminum, the driving shaft and the armature pole pieces being locked together in a die casting process.

Returning to the magnets the supplementary pole pieces which are made of soft iron laminations are also die cast into their aluminum cases and it can be seen in the lengthwise section that the laminations are brought a good distance back of the horseshoe. It is between the ends of these projecting supplementary pole pieces that the coil unit is placed. This consists of a soft iron core having a low tension and a high tension winding, so there is a magnetic circuit from one of the supplementary pole pieces through the core of the coil and back via the other supplementary pole. When the armature is in position the magnetic circuit passes from one main pole through a segment of the armature to one of the secondary poles, thence through the core of the coil unit and back via the second supplementary pole, opposite armature segment and south main pole.



Left—Section of two-spark model of Berkshire magneto for four or six-cylinder engines. Right—Section of a four-spark model for twelve cylinders. Center—View from rear end with coil unit removed and breaker box cover taken off

Left and Center—Four-spark, twelve-cylinder Berkshire magneto. The left view shows the way the coil unit and breaker mechanism can be removed. Right—A two-spark pattern for four cylinders

It is now possible to explain the condenser effect of this circuit. When the armature is rotating the passing of the iron portion across the faces of the pole pieces sends a series of magnetic "charges" into the projecting portions of the supplementary poles. Through the air surrounding the latter a certain amount of magnetic leakage can take place, so we may regard the upper and lower supplementary poles as the inner and outer coating of the condenser. The air gap provides a constant leak or discharge resistance so that the flux which passes through the core of the coil unit cannot be increased above a certain point.

This construction lends itself very readily to the four-spark system and the Berkshire company expects to make a number of this pattern. The four-spark machine, of course, runs at half the speed of the two spark type. It is slightly lighter than the two-spark model. The range of Berkshire machines includes a two-spark pattern for four-cylinder engines and for six-cylinder engines, while four-spark models are made for four-, six-, eight-, and twelve-cylinders.

Intensity Restrained at High Speed

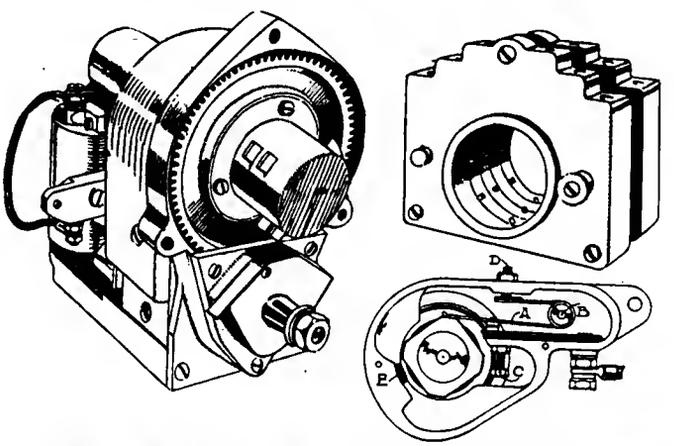
The makers point out that one great advantage of the four-spark system is that it provides a six-cylinder magneto with a very wide range of adjustment, 45 deg. being easily obtainable, this being 45 deg. on the crankshaft. The wide range coupled with the automatic limitation of spark intensity gives, in the Berkshire magneto, it is claimed, all the advantages of battery systems at low speed and of wound armature magnetos at high speeds with a practical elimination of the ordinary disadvantages of either.

Although they are making the two-spark type for use on engines already arranged of this kind of instrument, the Berkshire company believes very strongly in the advantages of the four spark. Fitted to a four-cylinder engine the four-spark machine only requires to run at half the speed of the crankshaft. With a six-cylinder engine at three-quarter crankshaft speed and at crankshaft speed with an eight, while the single magneto will fire twelve running 1½ to 1. The magnet used is a little larger and more powerful than would be required with a two-spark instrument in order to insure a strong spark at low speed but the self controlling action already explained allows the instrument to be designed for the slow speed spark since the possession of a hot discharge at 50 r.p.m. does not mean there will be an excessive current flow at 3000 r.p.m. or over. In every case the possible range of spark adjustment is doubled when the four-spark instead of two-spark machine is used.

Turning to some of the mechanical details of the machine this is made clear by the drawings and photographs. The breaker mechanism is rather interesting as the system of adjustment is somewhat novel. The spring *A* is one continuous piece of steel wrapping around the pin *B*, adjustment being provided at points *C* and *D*. The lower, insulated, platinum point is carried on a small strip of spring steel shown in the sketch, this being backed by a stout strip of red fiber. The upper screw *D* adjusts the tension of the breaker spring and the lower screw *C* controls the position of the breaker points. The whole breaker mechanism is easily removed for cleaning or adjustment. The coil unit can be pulled out by removing two screws and to have the parts in the condition shown in the photograph occupies something like half a minute.

Referring to the sectional drawings, it will be seen that a condenser is contained in a small round case and mounted on top of the upper supplementary pole piece, thence the high tension current goes to the central member of the distributer which carries a number of brass segments corresponding to the number of cylinders. In the outer part of the distributer are brass pins and between the pins and the rotating sectors there is no actual contact, the current jumping across a very small air gap. The safety gap is contained within the distributer and can be seen in the section of the twelve-cylinder magneto. The machines are characterized by light weight and extremely robust mechanical detail.

Electrically and mechanically the simplicity of the Berkshire magnetos renders them excellent manufacturing propositions. The solid, unwound armature, for example, can be made a close fit within the magnet without any difficulty, the coil unit is easy to wind and nearly all the non-magnetic parts lend themselves readily to die-casting.



The Berkshire magneto taken apart—A is one continuous piece of spring steel passing around the pin B, to the tension adjusting screw D. C is the breaker point adjustment and E a little wick lubricator which keeps the cam just greasy. The pins of the distributer are shown above and the sectors which spark to the pins in the view at the left

Peru Rear Axles in Two Styles

Easily Adapted to Car Makers' Needs—A Front Axle

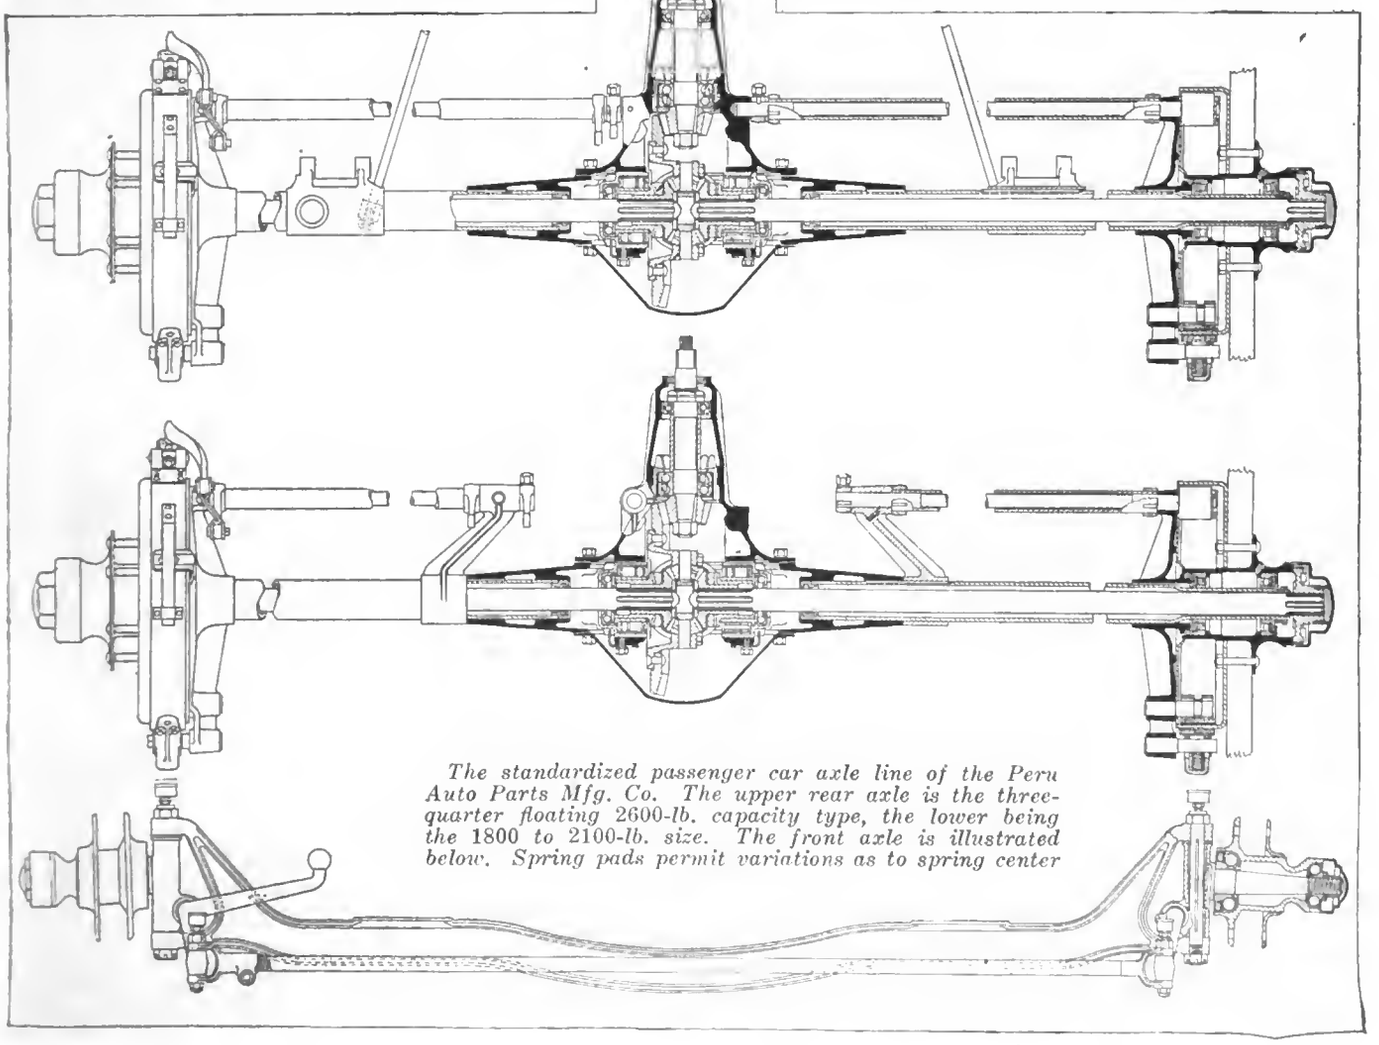
FOR current models the Peru Auto Parts Mfg. Co., Peru, Ind., is providing two styles of passenger car rear axle and a front axle. This is a standardized line, and, although fixed as far as fundamental design is concerned, can be varied to meet the fittings of different manufacturers as employed on their various models of cars.

The front axle is a conventional type, being a drop forged I-beam section from 1035 S. A. E. heat-treated steel. This steel has a carbon content of 0.35 per cent, from 0.50 to 0.80 manganese with maximum phosphorus of 0.045 and sulphur 0.05. The steering ball is forged integrally with the steering arm and cup and cone bearings are used in the hubs. The tie rod is of steel tubing having an overall diameter of ¾ in. and a wall thickness of 3/16 in. The spring pads are forged integrally with the front axle and they can be proportioned to accommodate variations in customers' requirements as to spring center.

The rear axles are made in two capacities; the 1800 to 2100 lb. size is the floating type and the larger, or 2600 lb. size, is a three-quarter floating. Both of these types are illustrated in the accompanying drawings. **The lighter axle, which is a floating design, has a malleable center housing with a pressed steel cover allowing for the removal of the differential as a unit without dismantling the axle or removing it from the car. A feature of this axle is that universal adjustment is provided for both differential and drive pinion. The wheels** are carried on roller bearings and the differential radial bearing is also of the same type with a ball thrust also provided.

As will be noted in the illustration, the pinion shaft is carried on a single row ball bearing at the forward end and on a double row ball bearing at the pinion. The reduction between the pinion and the ring gear is 4½ to 1. The differential is a four-pinion type and the ring gear is of heat-treated carbon steel. The drive pinion is nickel steel heat treated.

The side or driving gear of the differential are broached to take the standard S. A. E. six-spline axle shaft. Both these shafts and the pinion shaft are of high carbon steel heat treated to give them an elastic limit of 120,000 lb. The driving dog is of drop-forged steel which has specifications cor-



The standardized passenger car axle line of the Peru Auto Parts Mfg. Co. The upper rear axle is the three-quarter floating 2600-lb. capacity type, the lower being the 1800 to 2100-lb. size. The front axle is illustrated below. Spring pads permit variations as to spring center

responding to S. A. E. steel No. 1025. This is a 0.25 carbon content with 0.65 manganese, 0.045 phosphorus and 0.05 sulphur. This is pressed on to the axle shaft under hydraulic pressure and the drive is taken through six splines.

The brake drum is of pressed steel and has a diameter of 12 in. The brakes are double, having both an external contracting and an internal expanding set of 1¾ in. face width. A choice of connecting lever positions is provided, thus allowing for a wide range of variation in the actual mounting of brake linkage. There is also a wide permissible variation of possible spring centers as these are furnished according to the requirements specified and the type of spring hanger is also optional.

The construction of the axle leaves a considerable length of clean tube and it is this which permits of the variation in mounting of the spring pad. The tube itself is of heat-treated carbon steel and it is provided with thrust rods and diagonal brake rods to take care of the stresses which would occur in cars with long propeller shafts. The axle can be furnished for either a unit power plant, Hotchkiss drive or with flanges for rear axle transmission. When furnished for long propeller either a ball joint or a yoke connection can be provided as desired.

Grease Leakage Prevented

One of the features of this axle which should appeal to owners is the special provision made to prevent leakage of grease from the differential housing down along the axle shafts to the brake drums. There is a packing box located at the inner end of the tube which holds the lubricant in the gear well and any grease which should work its way past this would still be held separate from the brakes by the arrangement at the outer extremity and the provisions for tightness at the outer and inner bearing. The argument against the floating type of axle is that the bearing spread is often narrower than it should be. This objection has also been overcome by having the distance from center to center of these bearings quite far apart.

The three-quarter floating, 2600-lb. axle is similar in some respects to the smaller model as far as materials are concerned, although this larger axle is fundamentally a different design. There is a malleable center housing with a pressed steel cover and this arrangement, as in the smaller design, permits the removal of the differential as a unit without taking down the axle. There is also provision for adjustment of both the differential and the driving pinion, allowing wear to be taken up in any direction and to compensate for play between the gears after wear.

Roller bearings are used in the wheels. The differential radial bearing is a roller bearing also with thrust taken through a separate ball thrust bearing. The pinion shaft mounting is similar to that in the smaller axle as there is a single ball bearing at the forward or driving end with a double row ball bearing to take the load and thrust at the pinion. The ratio in this axle on the standard model is 4 to 1 and the differential is a four-pinion type.

As regards materials, 3½ per cent nickel steel is used for the pinion while the axle shafts are of special chrome nickel steel made from hot-rolled, heat-treated stock. The pinion shaft is of high carbon steel, heat treated, and the axle tubes are also of carbon steel, heat treated. The side gears are broached to take the standard S. A. E. six-splined axle shaft and at the outer end the hubs are keyed to the axle shaft and drawn up on a tapered fitting. The brake drums are 12-in. diameter pressed steel with both an external contracting and internal expanding shoe. The face width of the shoes is 1¾ in.

Leeway for the Car Builder

As in the smaller axle, the designers have been careful to leave the car manufacturer as wide a limit as possible in mountings of springs and brake gear. The spring centers on this axle can have a variation within any reasonable limit and the type of spring hanger can be as the purchaser desires. The axle is provided with fittings for rigidity, having truss rods and diagonal brace rods for long propeller styles. The axle can be adapted to the unit power plant, Hotchkiss drive or rear axle transmission unit.

Marmon 34 in New Closed Body Styles

The History of the Pneumatic Tire—11

Introduction of the Palmer Single Tube Tire—The Morgan & Wright Double Tube Hose Pipe—The First Puncture-Proof Types and Attempts with Pneumatic-Solids

The History of the American Automobile Industry—38

By David Beecroft

THE single tube tire, properly so called, was the Palmer type first made in 1892 and on the market in 1893 in which there was a homogeneous structure composed of a definite thickness of sparsely arranged cords or threads with the air tube inside and a thread outside with a valve for inflation. It possessed none of the characteristics of the hose pipe and its action under air pressure was to contract upon the rim and materially assist the same in folding it firmly thereto.

The Morgan & Wright Tire

The Morgan & Wright tire was what might be characterized as a double tube hose pipe, meaning that it was a hose-pipe tire in point of structure, with a slit 6 or 8 in. cut longitudinally on the inner side of the tire for the purpose of inserting a separate and separable air tube, said air tube having closed ends overlapping in the tire when in use. These two types last mentioned were the prevailing and mentioned constructions in use at this date with the so-called G. & J. clincher type of tires.

Between the years 1893 and 1900, Palmer tires or single tube tires and Morgan & Wright or double tube hose pipes were the accepted types in use on bicycles made in the United States, the Palmer occupying the high-grade field.

Quick Repair Methods Developed

Methods of quick repair were developed such as small syringes with needle points by which a thick gum could be introduced through a puncture and stop it by forming a wad on the inside. The tires were made of small diameter and therefore not likely to burst because the service was light and the inflation not great. So practically did these single tube tires perform their work that then as now the bicycle rider did not, as a regular thing, carry a repair kit.

Then, as now, however, to make security from puncture doubly sure, the protection strip of rubberized canvas between the air tube and tread portion of the casing was frequently suggested and was put on the market by the N. Y. Belting & Packing Co. in 1892, and Latulip of Syracuse used a strip of rawhide.

The self-healing tube made its appearance in 1892. The Luburg Mfg. Co. of Philadelphia brought out an air tube having an inner coating of viscous rubber which would close together after being punctured. This idea has been worked out in many forms since, some inventors putting this viscous rubber between two thicknesses of air tube material; others have rendered it better able to stop a large hole by mixing fibers of some kind, such as feathers, with this viscous material. The cost of this additional construction with its added weight was undoubtedly a considerable objection, and it seems not to have been common.

The First Puncture-Proof

The first puncture-proof tire to be publicly exhibited and to attract much attention was shown by Phelps & Dingle at a New York bicycle show in the winter of 1892-3. This consisted of an inner tube of printer's roll jelly which was elastic enough to close up an ordinary puncture so fully that very little leak occurred and which could be healed and permanently made tight by ironing it with a hot flat iron which would slightly soften the gum and join it together. The crowd around the Phelps & Dingle booth witnessing this wonderful solution inspired C. E. Duryea to do likewise and attract a similar crowd, which he did by pouring a half pint of pine tar disguised with citronella into a tire and inviting the puncture fiends to do their worst. Thus was invented the liquid self-healing device afterward patented by Duryea and used by the Buffalo Specialty Co., makers of Never-Leak, to control the self-healing business for 17 years.

The Pneumatic-Solid Type

In 1892 G. A. Burwell, afterward with the Lozier company, Cleveland, Ohio, invented a pneumatic tire, which, when deflated, served as a solid. This idea was frequently brought out and was exploited fully 10 years later by Munger for automobile use. Every attempt, however, met with failure because inventors would not recognize the unavoidable fact that the circumference of a tire is longer than its base. When deflated, the circumference rests on the part of the base prepared to receive it, but, being longer, there is an excess of material which must be gotten rid of and this can only be done by allowing the circumference to slip on the base or by folding in ridges.

The Rostrum

Likes Underslung Frame Design

EDITOR THE AUTOMOBILE:—Please publish an illustration of the Harroun heavy fuel carbureter, describing action, and give address of manufacturer.

2—The Mercer Automobile Co. built a car in 1915 similar to the previous model. Was it known as model M?

3—Is the Norwalk Motor Car Co. still in business? If not, when did they fail and where can parts be secured?

4—Why has the underslung principle been lost sigbt of by the prominent manufacturers? Was this construction more expensive or was there little demand for such a car? It did not appear freakish to me and was really as good looking as the best when on the market. It would appear that the present body designs could be carried out perfectly on the underslung car.

Anheim, Cal. R. E. H.

—The Harroun heavy fuel carbureter may be described as consisting of a type of carbureter baving the center of the mixing chamber inclosed in an exbaust jacket and thereby maintained at a very high temperature. THE AUTOMOBILE has no information regarding the details of the latest type. The manufacturer is the Invincible Mfg. Co., Pittsburgh, Pa.

2—M was a 1914 car. The 1915 models were radically different.

3—The Norwalk Motor Car Co. of Martinsburg, W. Va., is in a position to supply parts, altbough it has discontinued the manufacture of cars.

4—Tbe underslung principle has prohably failed to gain because it introduces considerable difficulties in design. Furtbermore, it does not actually lower tbe center of gravity. Tbe heavy part of the cbassis is the engine and this must he a certain distance above the ground to give proper clearance. This means that the center of tbe crankshaft is at a certain height and the driveshaft to tbe rear axle must be at the same beigbt. It is necessary to allow certain space for spring movement, so the position of the floor of tbe car relative to the ground is really settled hy the diameter of the flywheel. In the underslung car the frame is very low, the engine, transmission, etc., being high with respect to it and the body adapted to suit. With the ordinary car the engine and transmission stay in tbe same place wbile the frame is raised. It is easy to build an underslung car of the roadster type if the engine is well forward so that the flywheel is hidden bebind a sloping foot-board and room for the rear axle to move up and down is readily obtainable helow the rear deck. When the endeavor is made to work in the five-passenger body all sorts of trouhles commence.

Data on Dyneto Ford System

Editor THE AUTOMOBILE:—I have a Dyneto single-unit lighting and starting generator which was on a Ford. I want to use it to charge storage batteries using an electric motor to drive it. I will have some 12-volt and 6-volt batteries to charge. This being a 12-volt system, how will I reduce it to charge 6-volt batteries? Please give wiring diagram.

2—Where can I get a cut-out and an ammeter for this?

Nocona, Texas. R. A. F.

—It is not necessary to do anything to the Dyneto generator in order to charge 6-volt batteries. A dynamo which will charge a 12-volt battery will also charge any other battery of a lower voltage. In cbarging stations it is customary to use 50 or 100 volts to charge 6-volt batteries.

2—You can use the starting switch as a cut-out and you can obtain a suitable ammeter from the Dyneto Electric Co., Syracuse, N. Y.

Information on Horsepower Tests

Editor THE AUTOMOBILE:—Are all engines run at the same revolutions per minute when testing for horsepower?

2—At what speed did the model 75 Overland run to test out at 15.63?

3—Can you give specifications of the new four-cylinder Buick, and rated horsepower.

Helena, Mont. L. N.

—No. The engines are run with the maximum load at wide open throttle and the numher of revolutions per minute will depend on the characteristics of the individual engine.

2—The horsepower curve of the Overland model 75 was published in THE AUTOMOBILE for May 18 on page 903. This shows a brake horsepower of nearly 30 at 2100 r.p.m.

3—Tbe four-cylinder Buick runabout, known as D-4-34, and touring car, known as D-4-35, sell at $650 and $665, respectively, f.o.b. Flint, Mich.

The motor used is of the same overhead valve construction as the present six and is 3⅜ hy 4¾, developing 35 brake horsepower. Other specifications include: 106-in. wbeelbase, Delco ignition, Stewart vacuum fuel feed, 31 hy 4-in. non-skid tires, three-quarters floating rear axle, semi-elliptic springs on both front and rear, the front being 30 by 2 in. and the rear 48 hy 2. The car has three speeds forward and is geared 4 to 1 on bigh. Both the runabout and the touring car are huilt along the lines of the six and include practically the same equipment.

Charging a 1911 North East Unit

Editor THE AUTOMOBILE:—I have a 1911 North East motor generator taken from a Michigan 40 using an eight-cell battery. We wisb to use this machine to charge hoth 6-volt and 12-volt batteries, driving the macbine with a 1-hp. gasoline engine. This machine, as a generator, delivers only 5 amp. at 20 volts, which is not large enougb current for economical charging. Using the motor terminals as a series machine the amperage runs up to 15, whicb makes the load too beavy for the engine.

Can I use a rheostat to cut the amperage down or can the connections be changed in the generator so as to give the desired current?

2—Kindly publish this motor generator winding.

Pecos, Texas. R. E. W.

—Current regulation in this machine is obtained by means of a differential field winding, commonly known as a bucking field. Furtber regulation is obtained by introducing, at a predetermined speed, an external resistance in the shunt field winding.

By connecting terminals numbers 2 and 4 the starter gen-

erator will operate, in charging, as a differentially wound machine, the reverse current cut-out and the external resistance being short-circuited. By connecting the positive and negative leads respectively of the storage battery to be charged to terminals numbers 1 and 3 respectively of the starter generator, the charging rate can be regulated by varying the speed. A switch or reverse current cut-out should be in the battery circuit.

2—Fig. 1 illustrates the internal windings of this starter generator.

Testing Armature for Short Circuit

Editor THE AUTOMOBILE:—A Studebaker 35 with Splitdorf magneto runs perfectly on battery at all speeds, but will not run on magneto unless at 15 or 20 m.p.h. When the owner slows down for any purpose he must switch to the battery or the engine will die. I have had the armature out and the circuit is not open anywhere. Magnets have been recharged and everything done which should put it in good condition. I have concluded that one or more coils in the armature winding are shorted out and will produce current enough only at high speeds. If such is the case, what kind of instrument is used to test an armature for a short and where may I obtain one?

2—Please show me by sketch what points to cut in on for an ammeter on this car which uses the Wagner system.

Hickman, Ky. F. M. C.

—It is pretty difficult to diagnose a case of this kind, as there are many different conditions that could bring about the trouble spoken of.

First, the cam may be placed in reverse position, and this may be tested by rotating the armature just when it is ready to break away from the fields. This distance is about 1/16 in. At the same time the breaker must be in the advance position and the platinum points about to open. The proper distance between these points at full break is 0.031 in.

Although you state that magnets have been fully charged, it might be well to check this item over again. Inasmuch as you cannot throttle down below 15 m.p.h., it is possible there is a slight battery current passing through the armature winding. This would have a tendency to partially demagnetize the magnets.

One method frequently used in testing an armature for open circuit is to place a good armature in series with an ammeter and 6-volt battery. By closing the circuit, a reading can be obtained in amperes, and this would be a proper reading for an armature in satisfactory condition. Then place a defective armature in series with an ammeter and 6-volt battery and a higher reading in amperes would denote a defect in the insulation of the wiring. In other words, there would be less ohmic resistance in a defective armature than in a good one.

2—A method for installing an ammeter on this car is shown in the diagram, Fig. 2. You will note that this is placed between the leads *A* and the relay *Y*. Two long flexible cables No. 10 should be used in connecting the controller finger *A* and the relay *Y* to the ammeter on the dash.

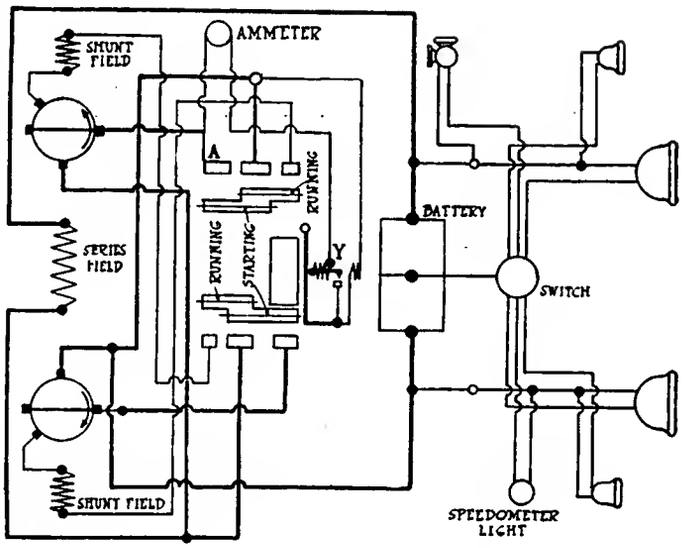

Fig. 2—Illustrating a method of installing an ammeter on the Studebaker model 35 between leads A and relay Y

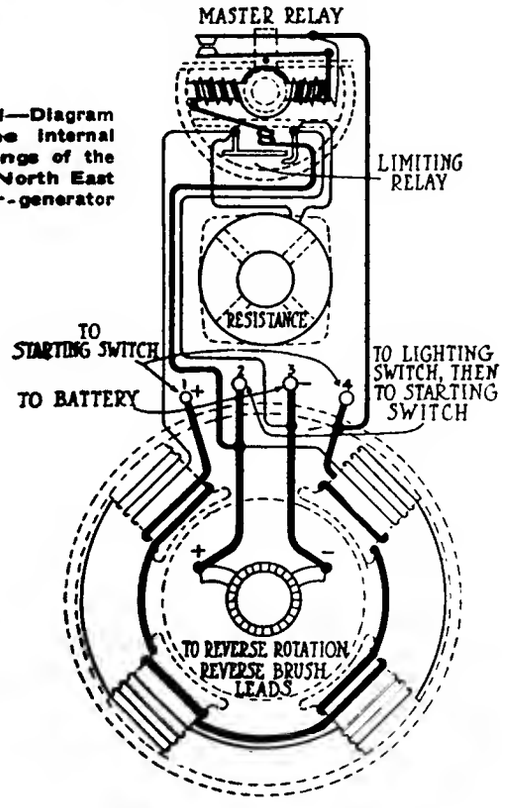

Fig. 1—Diagram of the internal windings of the 1911 North East motor-generator

Installing Starter on 1912 Hudson

Editor THE AUTOMOBILE:—Will it affect the operation of the Stewart vacuum gasoline system to put an air cock in the inlet manifold below the suction pipe running to the vacuum gas tank, said air cock to be operated from dashboard?

2—Kindly tell me the best way to install an electric starting and lighting system on a 1912 Hudson model 33.

3—Give names of several electric systems suitable for this car.

4—Will aluminum pistons decrease the vibration in this motor at high speed?

Lewes, Del. T. J. V.

—You might try the experiment, but unless the air cock is very small you will probably find that the vacuum tank will run dry every time you open the throttle wide.

2—The installation of the starting system on the Hudson model 33 will in no case be easy, which means that there is probably no particular system which would be especially suitable. A number of excellent inexpensive equipments are on the market and you would be best advised to apply to the best garage and repair shop in your district. They should be able to tell you the easiest system to fit from their own experience in applying equipments to other cars.

3—Answered under question 2.

4—It is doubtful whether aluminum pistons will make sufficient difference in the running of your engine for it to be worth while to make the change.

The Search for the Army Truck Wheel

(Continued from July 13, pages 60 and 61)

By Marius C. Krarup

USING the reference letters from Fig. 3, in the previous installment, it may now be shown that for steady running the advance of Q in Y is limited, though momentum may increase it usefully after a road shock.

If angle β is increased, l is increased but $R \sin \beta$ is also increased and the linear development of arc AC is increased. The general effect of increasing β from 45° to 60°, for example, which is near the limit where slippage of Q on Y may be feared, is ascertained by inserting the value of $\beta =$ 60° in the test formula. With $S_1 f_1 R$ and r unchanged l becomes 1.5 inch or 0.125 foot, and $\sin 60° = \sqrt{0.75} = 0.866$. Formula then gives:

$$t = \tfrac{1}{4}\sqrt{0.125} \times \frac{1000 \times 1.25 \times 0.866 + 260}{1000 \times 1.25 \times 0.866}$$

$$= \frac{2 \times 1.66 \times \pi \times 60}{360 \times m \times 1.466} \text{ second}$$

$$t = \frac{0.353}{4} \times 1.24 = 0.10943 = \frac{1.7467}{m \times 1.466} \text{ second}$$

The time for the fall of L has been increased from 0.08675 to 0.10943 second.

$$\text{As } m = \frac{2\ S \pi \beta}{360 \times t \times 1.466} = \frac{1.7467}{0.10943 \times 1.466} = 10.89 \text{ m.p.h.}$$

the velocity of the start has only been increased from 10.28 m.p.h. to 10.89 m.p.h.; indicating that this wheel system has a considerable range above the value of 45 deg. for β where vehicle speed on level ground cannot be strongly affected by speeding the engine, but this means also, of course, that acceleration and pulling power are similarly limited for any given design of the wheel and that it is useless to employ a motive power larger than required for maintaining Q at a position making β about 60 deg.

The relation of this power requirement to the value of L can be shown to make the weight of the load a smaller consideration than for normal driving wheels, provided the wheel dimensions and road conditions are such that f is not increased by the increase of the load.

On the other hand, acceleration and pulling power may be influenced largely by varying relations in the values for S, R and r, but such variations also affect the character of the wheel design. And the need of a design giving strength, compactness and lateral stability, as well as that independence of mud, sand and surface formations which goes with having S considerably greater than R and thereby raising the track for Q above the level of road troubles, imposes some limitations on design variations.

As acceleration depends less on ample power than on the ratio of L to $f \dfrac{(L + W + L_2)}{R \sin \beta}$, the weight moved can be very large if f is small and can be in form of a trailing load, T, making the total resistance $\dfrac{f\,(L + W + L_2 + T)}{R \sin \beta}$, and the suggestion is presented if this wheel type, with its relative independence of skillful manipulation of the clutch for starting, may not be especially adapted for the wheels of internal-combustion engine locomotives operating on rails with short trains of cars, as on feeder lines of railways, the traction being independent of slippery rails except in so far as the cause of slip in some cases also causes f to be increased.

To see how a minimum value for f affects starting and the conditions for acceleration, $f = 0$ may be used in the foregoing example, with $\beta = 60°$. The time for the unrestricted fall is here $0.353 : 4 = 0.088$ second, while $2S\pi\beta : 360 =$ 1.7467, and one has

$$m = \frac{1.7467}{0.088 \times 1.466} = \frac{1.7467}{0.128008} = 13.65 \text{ m.p.h.}$$

The change in the conditions for starting, as compared with the previous instance with $f = 0.20$ is not nearly as pronounced as it would be with normal wheels.

To a certain extent all these examples, and the test equation as well, represent an unreal condition, as in practice Q is brought to angle β by a gradual engagement of the clutch and has some angular speed when it gets there. Also, the vehicle begins to move as soon as the pressure of L passes beyond angle α, the angle of equilibrium with traction resistance. But the test formula furnishes a measure of the forces that influence operation without complicating the subject with inertia and acceleration.

The rate of acceleration for a perfectly uniform road condition is easily figured, but the maximum speed attainable is of course subject to many limiting factors in practice—such as tire resistance, air resistance—which it would be too difficult to introduce.

Taking it as unmistakable that the power transmitted from the engine by the rotation of Q takes effect as gravitation of load L at the point c, one has that the acceleration factor in the continuous tendency to falling, which the rotation of Q counteracts, is so much less than 32 ft. per second as $f \dfrac{(L + W + L_2)}{R \sin \beta}$ is smaller than L.

giving $g = 32\left(1 - \dfrac{f\,(L + W + L_2)}{L.\,R \sin \beta}\right)$

In the example, this makes $g_1 = 22.72$ ft. per second. But some difficulties are encountered in perceiving exactly how any value for g_1 can be applied to the vehicle speed, so long as it seems evident that acceleration must result in a gradual increase of β until power and resistance reach equilibrium and speed becomes uniform, and it may be sufficient here to note that the limits for acceleration seem to be determined by the power, if this is scant, but by the highest practicable value for β if the power is sufficient for making Q advance to the maximum angle, the load and the traction resistance considered.

The power required for moving $f\,(L + W + L_2)$ at the rate of $m \times 1.466$ ft. per second is

$$f\,(L + W + L_2) \cdot \frac{m \times 1.466}{550} \text{ horsepower.}$$

since 1 hp. raises 550 lb. 1 ft. per second.

And, with the values for the traction resistance factors used in the examples and a vehicle speed of 10 m.p.h. ($m = 10$), this gives one expression for the required power P,

$$P = 260 \times 10 \times 1.466 : 550 = 6.93 \text{ hp.}$$

It should be possible to figure the movement of Q representing the same horsepower and probably another formula representing the limitations of the system for application of power, giving the maximum as a function of load and other factors with a certain maximum β assumed. But so far the effort made for producing such a formula has run into complications, mostly due to uncertainty in grasping the exact mechanical nature of the work done by Q. Without attempting a formula, it seems plain enough that natural acceleration will permit considerable road speed if the engine power is sufficient to produce a large β, and that even a small β will produce vehicle movement under circumstances

which would require an exceedingly low gear with normal wheels as well as perfect adhesion in the road contact.

Rough roads, upgrades, downgrades, braking, slippery roads and interchangeability with normal wheels are factors which were mentioned before as representing other conditions which the composite wheel should meet if it is to be considered.

Little need be said about the effect of roughness of the road surface, as practical tests only will satisfy. While the composite wheel has more adaptation to roughness than the normal wheel and must tone down the horizontal component of shocks, it must also re-adapt itself to the running after a shock, and the total effect is not easily realized mentally. As in the case of normal wheels, road obstacles of considerable size and rising sharply from the surface can only be overcome readily by momentum. But the retardation in such cases will mainly affect the component Y, while the vehicle continues going forward and is liable to bring β momentarily to almost 90 deg., whereafter Y, with its small weight, probably will be readily turned over and carried along without any injurious impacts, provided the central device in the wheel (see Fig. 1) maintains steady contact between the two components.

The Action on Grades

The efficiency on upgrades is the worst operative feature in the wheel if speed is the requirement, because the grade reduces the leverage with which the gravitation of the load can operate to overcome traction resistance. But ability to get up, if only at a crawl and even if the grade is slippery, is the compensating advantage. If DA, Fig. 4, represents a grade of γ degrees, the maximum operating angle is reduced from β to $\beta - \gamma$, and the leverage is reduced from $R \sin \beta$ to $R \sin \beta - S \sin \gamma$.

On steep grades f is fortunately as a rule low, because sand of the kind producing a 20 per cent f does not stay on hills and moisture also is drained off. If the angle γ means a 15 per cent rise and the traction coefficient proper is 5 per cent, the f with which the total traction resistance on the hill must be figured, becomes 0.20, as in the examples relating to traction on the level, but the reduced leverage must make progress slower. In the tractors with propulsion of this type, which have been used for work of still more refractory nature, the special disadvantages on steep hills were overcome by making S little larger than R and r considerably smaller, but the result of this choice of dimensions

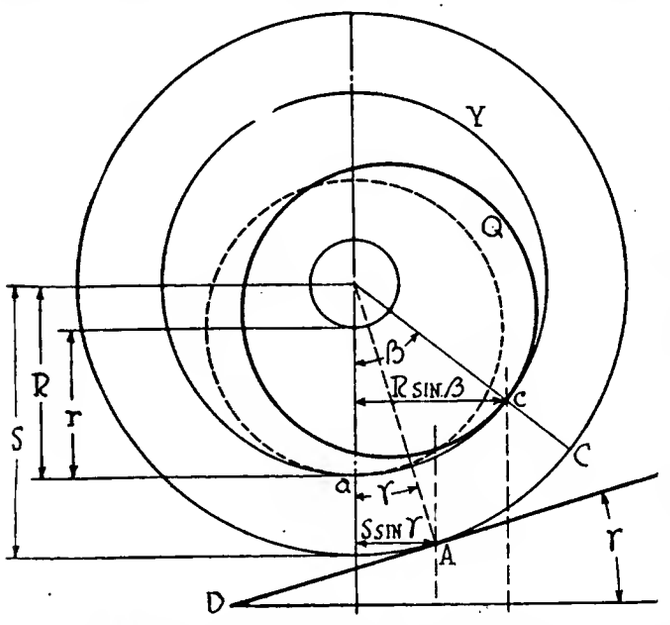

Fig. 4—Diagram of main factors coming into play with driving wheels of the composite type on road grades

was not a wheel but a special tractor-truck construction. As the system permits some rate of progress under conditions which stall ordinary motor vehicles, however, even if the proportions are consistent with the preservation of the mechanism as a wheel which can take the place of a normal wheel, and as conditions absolutely requiring different proportions to make sure of effecting progress are rare, there still seems to be room for experiments with the composite wheel type to arrive at dimensions and proportions suitable for those forms of military or civilian transportation work in which certainty of pulling through is more important than rapid acceleration and speed on hills, and for other work, such as quarry and excavating work or hauling of stone, gravel, sand, in which it may be an economical advantage to be able to use a small motive power and yet be sure of getting the work done. Immunity to slip where other wheels fail and the chance of perfecting a construction which by adjustment may be turned into either a wheel functioning normally or a composite wheel, naturally constitute weighty considerations in the same connection. The same may be said of the suitability of the type for traveling at good speed on fair roads.

Fig. 4 may be looked upon as representing downgrade travel as well as upgrade, by reversing the supposed direction of travel, and if any difficulties can arise which are not the same as those occurring in uphill work and due to the shortened leverage with which the power operates, they must be traced to the possibility of the vehicle running away from control by the power and the brakes. As the brakes operate on Q, to which the brake drum is secured, and Q runs on a guaranteed friction surface in Y—its tracks—and as it is of smaller diameter than a normal wheel and can be blocked more securely by brake action, if necessary, the chance of Y carrying Q beyond its slipping angle can scarcely be perceived as actual.

If the vehicle is to be held at rest on a grade, Q will naturally be brought to its lowest position in Y, but Y will at all events be prevented from rotating more than a few degrees if Q is held, and in starting uphill after the stop the conditions are not materially different from starting on the level, except that Q must advance to a larger angle before vehicle movement begins. In this respect the advantage seems to lie with the composite wheel type, and in the applications for which it is suited it might furnish the opportunity for doing away with one of the two sets of brakes now usually employed, since one set can readily be made to act as service brake and emergency brake combined. If it were to be expected that trouble with the system might arise through very careless operation—as when allowing the vehicle to run wild downhill—a dragbrake could conceivably be developed which would furnish the needed security and would be unexceptionable for the class of vehicle for which it could be wanted.

In considering the possibility of Y slipping on a road which would cause slipping of normal driving wheels, the fact that the power is not applied at the road contact, but continuously tips Y around the point of road contact as a fulcrum, seems decisive. Slipping of wheels is indeed inconceivable so long as the frictional contact of Q with Y is intact, as any actual slip would bring Q in advance of the point of ground support, if it were not there before, and gravitation would thereafter necessarily take effect to turn Y and move the vehicle forward. Only if $(S - R)$ were extremely small and Y a substance having no mass could it be conceived that Q in its rest position, contacting with Y immediately above its point of ground contact, could by its own rotation impart a stationary rotation to Y without changing its relation to Q. Even this remote possibility—with which reality has no better parallel than the immersion of part of the wheel in a greasy hole offering practically no friction to hinder the rotation of Y—is rendered remoter still when S is appreciably larger than R, so that Q's point of contact with Y when at

rest lies some distance above the point of ground contact of Y. On the whole, however, and with dismissal of far-fetched objections, the security against wheel slip lies practically in the impossibility of having any abnormal resistance to the first advance movement of Q in relation to Y, whereafter gravitation must take effect imparting a rolling movement against which a slippery road is harmless.

With slip and spinning of wheels impossible, skidding becomes improbable, as generally understood. And, with the frictional contact of Q with its track safeguarded by the materials used and by its elevation above the road level, the ordinary differential gear is made to operate properly without fail.

These properties of the composite wheel are apparently raised above reasonable doubt more securely than any other merits that might be claimed for it.

Interchangeability with Normal Wheels

When Q makes 1 revolution Y turns r revolutions divided by R, and to make the same vehicle speed as a normal wheel with the same height of axle by rotating Q with the same angular speed as the normal wheel, the radius S of Y in the composite wheel must be in the same proportion larger than R as R is larger than r, and $S - R + r$, being the height of the axle, must be equal to the radius of the normal wheel. These proportions are easily materialized if the eccentricity of the wheel components can be made large—as by having $r = 12\frac{1}{2}$ in., $R = 16\frac{3}{4}$ in. and $S = 22\frac{1}{4}$ in., to replace normal wheel of 36 in. diameter—but will make Y stand $8\frac{1}{2}$ in. higher than the normal wheel, necessitating a change in mud guards, if any are used. Better results might be obtained by allowing the composite wheel to raise the total gear ratio of the vehicle somewhat, since the higher torque of the lower gear can probably not be utilized anyway. But with the dimensions just referred to, or other ones in the same proportion, the composite driving wheel can built without departing from the general lay-out of construction features indicated in Figs. 1 and 2.

In order to make it practicable to transform a composite wheel into one operating on the normal plan—by incorporating an expanding element in Q by which it could be raised to concentricity with Y and braced against its tracks—a smaller eccentricity than that indicated in the dimensions referred to would of course be desirable. Probably nothing but experimenting can furnish the best compromise solution in the matter of dimensions.

To advance consideration of the type to a practical stage there are still lacking satisfactory formulas for (1) vehicle acceleration, for (2) the relation of β to vehicle speed and for (3) the maximum applicable power as a function of the load. To their production the writer will shortly devote as many hours as may be required for making the conclusions final.

Paragraphs on Current Topics

By Marius C. Krarup

Motto: Radical Thought, Conservative Action

News from the motor cars and trucks "somewhere in Mexico" may not be what the general public is yearning for most impatiently, but it is sadly amusing to reflect that it is delayed and mystified principally because the Japanese found concealment of military movements a good policy in the Manchurian campaign of 1905 and reduced the pristine war correspondent to a transmitter of rear guard small talk. The Balkan powers copied this innovation and enjoyed the resulting freedom for atrocities. And now, in Europe as in Mexico, although reconnoitering by aeroplane and transmission by wireless render the precaution futile—each belligerent knowing full-well and all the time what the enemy is doing at his front and 100 miles behind it—the precious phrase "somewhere in ——" has come to signify patient acquiescence in a secret-mongering method the justification for which has ceased to exist. Perhaps we should ask the Japanese how they would proceed now, when secrecy is effective only against friends at home, to turn the broadest kind of publicity to good account for war purposes.

□□□□

Between 11 and 12 o'clock last Friday night the sun threw on a screen right before the eyes of all New York and before millions of Americans in other States a stupendous moving shadow show of the war in Europe. And it was a show of the war operations of the following morning at dawn. Yet no poet has sung about it, and the newspapers called it an eclipse of the moon. Yes, the moon was the screen, and over it was moving in sharp contours the shadow of that edge of the earth where the sun was rising over renewed Russian assaults upon the German lines—those of Saturday morning, which were reported by cable 24 hours later. Thousands of American motor trucks with ammunition were lined up at the rear. Some of them were moving forward when caught by the horizontal rays of the star of day and projected in black against the luminous disk which we were intently observing. An aeroplane arose. A huge shell exploded. Pandemonium reigned. All became blurred. The shadows shuddered. Then quiet; the dawn had reached Poland where there is a solitude that they call peace. But no, the edge of daybreak runs northwesterly, and further South, in Bukowina, we suddenly see the outlines of Cossacks with their lances charging furiously over the crest of the hill. The show moved fast. Even war does not stop the earth's rotation or delay it a second. Somewhere the shadow passed over Wilhelm and his sheltered sons. Nothing was projected. They slept. There was an intermission of a half hour. The cosmic operator of the light was sweeping his tell-tale rays over the domains of the central powers where nothing stirred against the illuminated horizon. At last they passed into France. A glimpse of Verdun at sunrise. Only thousands of little black dots—a curtain of artillery fire—were leaping over the screen close to the edge of the earth's shadow. Then it was past 12 o'clock. The show was over. The rest of it missed the background until then providentially supplied and vanished into the universe.

□□□□

Only the lack of mechanical facilities for magnifying the optical dimensions of this wonderful spectacle, this marvelous feat in instantaneous news reporting, kept the public at large from witnessing it. Some day civilization will be prepared for such opportunities, but we think it a duty to record now exactly what so many might have seen with their own eyes. And incidentally we come to think of the many other excellent photographic illustrations of important realities which miss their usefulness entirely because they are printed too small—in our esteemed contemporaries, of course.

□□□□

If the Service Station is a permanent adjunct of the big manufacturer's sales department, an incubator for good will and repeat orders, and if it pays for itself in the large cities and aggregations, what is to be the means by which its benefits may be extended to minor towns and to the customers of smaller manufacturers? It is a unique institution with no parallel in any other industry; a distinct invention to

meet a want. So long as repairmen in general may not be confidently relied upon to handle each and every make of car or truck with full understanding of its peculiarities, with the assistance of ready access to spare part supplies and with a desire to do justice to the construction and the customer, the specialization of skill and facilities found at the service station must remain a great mutual advantage for maker and user. And it has found another mission in teaching maintenance methods for commercial motor vehicle installations. Nothing short of a comprehensive organization of repairmen, ready to co-operate with manufacturers in severalty, seems to be in sight for extending these benefits where they are now not enjoyed. As an introductory step perhaps the manufacturer's book of instructions for his customers could be edited more directly for the benefit of the repairman than it usually is.

□□□□

The exalted motive which keeps people from committing faulty mathematics occasionally may be respect for the science or it may be fear of being found out and declared a dunce, since mathematics and mathematical physics have a way of tracing the transgressor without leaving a loophole for escape. But this most stringent and conclusive form of reasoning will never be very popular and useful so long as it is held sacrosanct. Something that nobody dares to blunder in is not going to be practised extensively, and without frequent practice what is to become of the meager skill with which the graduate starts in his profession? Integration, a most useful mental process, is almost tabooed in discussions, killed by an overdose of reverence. If we could learn to laugh and joke in algebra, calculus would soon become a chummy companion of common thought. Even analytical geometry might begin to talk with human voice, showing its curves through the mask of its equations, and it might become a real sport to work out its secrets with arbitrary asymptotes suitable for a practical occasion—as might be very useful in designing mills for cutting gears or cams of special shapes. But first we must have many errors and many to point them out.

□□□□

According to a volunteer statistician 3217 women drove motor cars for pay in England a few months ago, and their number was increasing fast. As soon as cured of affectations of timidity they drive as well as men, it is said, but not quite so fast. That they should ever give up this occupation seems improbable. And similar reports come from Berlin. In a few years the example must take effect here. But the prospect has no problems. Everybody can apparently afford to await its natural development without impatience.

□□□□

The demonstrator salesman pulled his car up short near 14th and Broadway and his eyes swept over the swarm of motley humanity, mostly in stockings, that was hustling home to the tenements from the daily work. "Look at them," said he triumphantly to his prospect; "nearly every one of them will be taken 'as is' by somebody, to be supported for its natural life, and think of the upkeep. That's easy instalments for you. That's what it does. Anything goes on that plan. You don't have to make things right if you are going in for easy payments, and you don't, of course." The prospect very quietly said something about modern manufacture certainly being ahead of nature in the uniformity of the product, and the demonstrator took it for consent.

□□□□

Ethical, reformed advertising represents one of the latest patriarchal movements for the public's protection and the purely moral satisfaction of the protectors. A fine movement, for a change; for those who need the change. But the art of truth-telling is remarkably difficult. While "yielding to no one in veneration of veracity," one may yet have misgivings. A good advertisement is brief and the whole truth is long. Must the little doubts which are to result in next year's improvements be handed over by the concientious principal to the expert writer of advertising matter with injunction to cry about them from the housetops? Discrimination between facts which the public can understand and those which the majority would misunderstand raises a nice issue in casuistry and a problem in competence. Many among the public prefer the mental exercise of picking the winner in a spirited contest in plausibility, rather than surrendering their critical acumen and accepting instead a blind faith in the conversion of those advertisers who make it a point to subscribe to the purified creed. And a trusting public would delay progress. The longing for the near-millenium is also assuaged by reflecting on the enormous profits which No. 100 could garner by sophisticating skillfully now and them, if his 99 competitors had schooled themselves to a more complete frankness than the average individual is able to practice within his own mind. The agitation of the subject may be timely, but a guardianship for the public would be the saddest of all things, a serious burlesque.

□□□□

In the age of mergers and economies, both true and false, the theoretical publicist who has not grasped the force of specialization expects co-operative advertising will be more and more employed. What is it? We offer a sample (illustration omitted):

The modern Omar and his Thou pull up under that tree in a comfortable little 1917 *Arethusa* car,
Draw from the dainty *Beowulf* lunch basket with ice compartment ($5.22 at *Christopher's*)
A box of the celebrated *Dania kiks de seigle* (all grocers),
A gastronomic confection of stuffed dates from *Erk & Filford,*
And a *Thermos* bottle filled with delicious decanted *Chambertin* (Type) from *Gamache.*
Leisurely they nest their feet on the cushioned *strapontin-en-banc, Hustler's* patent.
And why shouldn't they be able to feel pretty cozy, especially as that book of verse is
The latest best seller, the *Ideocrat's Jodlings,* ($1.50) in *vers libre;*
That marvelous form of speech which is relieved alike of prosaic and poetic restriction?

□□□□

In the midst of war's horrors, reports *American Motorist* from the trenches, the high-spirited *poilu* has invented the word *tacot* to designate an automobile that is below par. Too late! *Tacot* antedates "ice-wagon" in the international dictionary of slang. The word grew whiskers, so to say, before the *poilu.*

□□□□

Let no tradesman be deceived if he hears that shark-absorbers are in great demand at New York and New Jersey seaside resorts.

□□□□

Be a gangster! Modern life is complex and subdivided. Its human unit is no longer the individual but the gang, a gang controlling a full assortment of abilities. Success and satisfaction are measured by capacity for association with others who supplement you. The commonest mistake is not loneness, but choosing for associates those who duplicate you. That does not make a gang but a mob. Don't be a mobster!

□□□□

This is in brief The Boundless Gangster Philosophy with regard to which we have been honored with an inquiry.

Production

NO better proof could ever be asked of the quality of American passenger cars than the fact that although in 1916 we have only 99 factories as compared to 270 in 1911, yet the production for the first half of 1916 is 754,902 as compared to only 200,000 for the entire year of 1911. In other words, four times the number of cars have been made by one-third the number of plants in half the time.

What was good has survived and been improved upon, and yet the cars of to-day are 35 per cent less in price than they were 5 years ago. Better methods, better machinery, better factories and the more economic handling of labor have been the reasons for the combined facts of greater production and lower-priced cars. In some factories the overhead per car has been cut 200 per cent and more in 2 years. In others double the production has been secured from the same number of men.

Greater production has demanded higher efficiency in other departments. It has meant the creation of a bigger market with the ever-present demand of lower cost per car in selling. Less unit-cost is the story of the entire automobile business. It means less per car to make, less per car to sell and less per car to purchase, and the saving in each of these three fundamental departments has been reaped by the consumer who pays one-third less for his car now than he did 5 years ago.

Selling as a Science

THE World's Salesmanship Congress held last week in Detroit accomplished much if it did nothing more than impress on those salesmen present the deplorable lack of facilities for the preliminary training of salesmen. The congress has done more in that it has made a start towards placing salesmanship in the ranks of sciences, where it rightly belongs.

The young man who aspires to be a doctor or surgeon has within his reach medical schools in which he can take a complete course in medicine or surgery so that when he starts practice he is scientifically prepared for the work. He is a graduated physician.

So with the profession of law, those who aspire to its ranks have schools for preparing themselves, and who would think of beginning the practice of law without first having absorbed the known principles of the law.

In engineering circles the same rule applies, our leading engineers are schooled in the sciences at our universities before they attempt the work of design and construction, a knowledge of fundamentals of engineering principles being essential for any person attempting to succeed in the engineering field.

But turn now to salesmanship, that great essential of this ultra-commercial age, and we are lacking in those great institutions for the scientific education of the salesman. Too many of our salesmen start into their profession as laws unto themselves, without previous education in the essentials of the profession, and perhaps without definite knowledge of the fundamentals of salesmanship. The large manufacturers or industrial houses do not care to place the sale of their commodity in such hands. The Salesmanship Congress has recommended in favor of such educational work and such a movement deserves the united co-operation of the automobile industry.

Recognition

AFTER all the valuable work of standardization accomplished by the Society of Automobile Engineers it is no surprise that the army and navy should look to the society to carry out the aircraft standardization which is so urgently needed. None the less, the holding of an S. A. E. meeting in the Bureau of Standards at Washington, the home of national standardization, unquestionably marks a stage in the development of the society, and will cause July 18, 1916, to be a memorable day to all those who have been leaders in the S. A. E. since its inception.

When the government authorities found the vital need for standards of dimension in aeroplanes the S. A. E. appealed to them as being the natural and proper body to carry out the work. Aided by the accumulated experience of automobile standards, supported and assisted by the army, navy and Bureau of Standards, the new aeronautic division of the S. A. E. committee ought to find that very rapid progress is easy.

S. A. Wants American Cars

Beecroft, After 10-Weeks' Trip as U. S. Delegate, Reports Big Field

NEW YORK CITY, July 18—David Beecroft, directing editor of THE AUTOMOBILE, has returned from a 10-weeks' trip to South America, where he went as a delegate of the United States Government to investigate trade conditions in Argentina with special regard to the automobile industry in that country. Mr. Beecroft was a member of the Argentine Return Visit Committee, the visit following a similar one made by delegates from the various countries in South America in 1915 as representatives of their respective governments.

While in South America Mr. Beecroft traveled extensively through Argentina, and also Uruguay and Southern Brazil, and reports that the U. S. A. automobile has been meeting with greater success in these countries during the past 18 months than ever before in its history. The sale of expensive European cars has practically been at a standstill for 3 and nearly 4 years, but the American car has demonstrated that it can stand up in the country districts where roads are not to be compared with those in this country, and as a result there is a great demand among dealers in all three countries for agencies of lower-priced American machines.

An exhaustive series of articles on the automobile, automobile accessory, motor truck and motor tractor situation in these South American countries will follow from week to week in THE AUTOMOBILE. This will be the first opportunity the automobile reading public of the United States will have had of so extensive a series of articles dealing with all the problems directly connected with the automobile industry as existing since the opening of the European war. The first of these articles will appear next week.

—

Neville Co. Absorbs More-Room Steering Wheel Co.

DETROIT, MICH., July 14—The Neville Steering Wheel & Mfg. Co., this city, has absorbed the Neville More-Room Steering Wheel Co. F. A. Vollbrecht, formerly general manager of the King Motor Car Co., is president of the new corporation, John V. Harding is vice-president and A. W. Webber secretary and treasurer. Harding is known in the trade through his 6½ years' work as special factory representative of the Motz Tire & Rubber Co., and later the Goodyear Tire & Rubber Co., in Detroit and the country at large. Webber was formerly of the General Motors Co. The new company has obtained fireproof quarters at 74 Congress Street West, Detroit, where it is now devoting its energies exclusively to manufacturing a full line of Neville More-Room steering wheels. William Langton has been appointed factory superintendent, and the factory is now producing its wheel in quantities to take care of both manufacturers and the jobbing trade.

—

Aland 16-Valve Four Coming

DETROIT, MICH., July 17—Organization plans are under way for the Aland Motor Car Co. of this city. According to R. C. Aland, chief engineer, the company is about to incorporate for $500,000 and plans to produce, starting in December, a lightweight car fitted with a four-cylinder sixteen-valve power plant.

—

Allen Offers New Model at $850

FOSTORIA, OHIO, July 17—The Allen Motor Co., this city, has announced a specially finished car to be sold at $850 f.o.b. Fostoria. This new car will be known as the Allen Classic with the standard Allen chassis and body, finished in brown with gold striping, black fenders and radiator. The upholstery is Spanish brown in color. The offering of this new model will in no way interfere with the production of the Allen 37.

—

Cars to Go on Tracks

MILL VALLEY, CAL., July 17—H. S. Johnson, a mechanical engineer at present with the Mt. Tamalpais & Muir Woods Railway, is forming a company to manufacture gasoline automobiles to operate on railroad tracks.

—

Armored Cars to Have King Chassis

DETROIT, MICH., July 17—The Armored Motor Car Co. has been formed to manufacture armored automobile bodies. The principals are at present in Washington, D. C., and plan to stage, soon, a test for the inspection of the government. The company plans to use King chassis.

—

Levy Takes Marion-Handley

CHICAGO, ILL., July 18—James Levy, the former Chalmers dealer in this city, has taken over the Marion-Handley car. The James Levy Motors Co., the name of the new company, will be located at Twenty-third Street and Michigan Avenue.

—

Bowler Is H. A. L. Sales Manager

CLEVELAND, OHIO, July 17—George H. Bowler has been appointed sales and advertising manager of the H. A. Lozier Co., this city, to market a new H. A. L. twelve.

Crew-Levick Co. Sold to Syndicate

New Yorkers Buy Out $5,000,000 Manufacturers of Perfection Oils, Etc.

PHILADELPHIA, PA., July 18—The Crew-Levick Co., one of the oldest major refiners and distributers of petroleum products, with refineries at Chester and producing properties at Titusville and Warren in this State, has sold out to a New York syndicate. The Crew-Levick Co. is chiefly known to the automobile trade as the manufacturer of Perfection oils and greases and recently has added a number of other petroleum products to its line, including grease tubes for quick filling of grease cups, Mistokleen, a body cleaner, as well as other products.

The company is capitalized at $5,000,000 and the sale price is approximately $125 per share. It was first rumored that the purchaser was allied with the Standard Oil Co., but this is denied by Crew-Levick.

—

Reliance Engineering Acquires Hercules Forge Co.

LANSING, MICH., July 8—The Reliance Enginering Co. has purchased the Hercules Forge Co., Indianapolis, Ind., the deal having just been closed. The Indianapolis concern sells equipment only and no real estate nor shop buildings were included in the sale. All equipment will be moved to this city and installed in the building formerly occupied by the foundry of the Seager Engine Co., which company has been taken over by the Reliance company. This building will be equipped for drop forging exclusively and the Hercules company equipment is for general extension of the Reliance engineering department.

—

Eubanks Resigns from Barley

STREATOR, ILL., July 13—It has been announced that P. J. Eubanks, sales and advertising manager of the Barley Mfg. Co., of Streator, has tendered his resignation, to become effective Aug. 1.

While no announcement has been made relative to Mr. Eubanks' future plans, it is believed that he will take a protracted vacation and much needed rest before again taking up active work.

—

Humphrey Joins Briscoe

JACKSON, MICH., July 14—S. H. Humphrey, formerly vice-president of the Chalmers Motor Car Co., has been elected vice-president and manufacturing manager of the Briscoe Motor Corp., this city.

Mr. Humphrey has been connected

with the automobile industry since its inception, starting as a mechanic at the Peerless factory in Cleveland. His first connection with the Briscoe Brothers was in 1908, when he went to the Brush company as works manager. For several years he was manufacturing manager of the Hupp Motor Car Co., leaving that company to become vice-president of the Chalmers.

—

Drexel Succeeds Farmack

CHICAGO, ILL., July 17—The Drexel Motor Car Corp. has succeeded the Farmack Motor Car Corp., and is issuing stock at $10 per share. It is capitalized at $2,000,000.

—

Gillett Buys Out Wilmo

CHICAGO, ILL., July 17—The Wilmo company, manufacturer of accessories, has sold its property, patent rights and good will to the Gillette Motors Co., Mishawaka, Ind. King C. Gillette is president.

—

G. H. Smith Mercer Sales Manager

TRENTON, N. J., July 13—G. H. Smith has been appointed sales manager of the Mercer Automobile Co., this city.

Mr. Smith has long been known in automobile trade circles, having been with the White and Peerless companies.

52 Saxons in 3000-Mile Relay

—

Sixes To Try for Transcontinental Speed Record—Will Carry Messages

DETROIT, MICH., July 16—Fifty-two Saxon six cars will relay from New York to San Francisco, by way of demonstrating what can be done with an automobile as the bearer of messages over long distances. They will race at top speed for stretches of about 75 miles each.

Starting Saturday morning from New York City, a Saxon car will enter the Lincoln highway, which leads from coast to coast, and will travel the first lap of the journey. A message from Mayor Mitchel of New York to Mayor Rolf of San Francisco will be handed the driver just before the start, which will be passed along the line and eventually delivered at the city of the Golden Gate.

—

Hood and Botterill Open Offices in Detroit

DETROIT, MICH., July 17—A new wrinkle as regards having permanent representation in Detroit so as to insure prompt shipment of cars, materials, accessories and other supplies has been worked out by at least two parties, one being Tom Botterill, distributer of Hudson cars for Utah and Colorado, with headquarters at Salt Lake City and Denver, and the other is the recently formed Wallace C. Hood Service Bureau. Mr. Hood was formerly connected with the Chalmers, Everitt and Empire companies.

The former differs from the latter mainly in the fact that Botterill's establishment of a Detroit office with A. S. Broadhead in charge, was done to seek closer touch with the Hudson factory only, while the Wallace C. Hood bureau is organized to help any manufacturer, jobber or distributer, acting as his representative in securing prompt shipments, following orders through production at any factory, and in fact assisting automobile manufacturers or distributers who have been working at a disadvantage through lack of representation in Detroit and Michigan.

—

Grossman Holds Sales Conference

BROOKLYN, N. Y., July 17—The annual sales conference of the Emil Grossman Mfg. Co., Inc., this city, took place July 14 and 15. The first conference opened at the executive offices of the company in Bush Terminal Building No. 20 on July 14 and adjourned for the second conference on July 15 at the Brighton Beach Hotel, Brighton Beach, L. I. Policies for 1917 were formulated at this

Big Dealers' Upheaval in New York

(*Continued from page* 85)

1826 and 1828 Broadway, in which are now being exhibited Overland and Willys-Knight cars, and also the establishment and equipment of a service station at 150th Street and Gerard Avenue, the Bronx, in a building of 60,000 ft. floorspace. It is the intention of the company to open immediately sales and service stations in Brooklyn and Newark.

The new building which is in process of completion is located on Fifty-seventh and Fifty-eighth Streets, between Tenth and Eleventh Avenues. This building is partially completed at the present time and when finished will have a floorspace of 300,000 sq. ft. and will represent an investment of about $1,000,000.

E. B. Jackson, formerly president of the Packard Motor Car Co. of New York, has become associated with the Willys-Overland company of Toledo in an executive capacity. He will make use of his experience and knowledge of metropolitan needs by devoting a large part of his time to the creation and development of an organization in this territory.

In reference to E. B. Jackson going over to the Overland organization, the Packard company in this city and Philadelphia have appointed new heads of these branches. E. S. Hare, recently appointed manager of sales of the New York Packard branch, and formerly vice-president of the Commercial Truck Co., Philadelphia, now becomes general manager of the Packard branch in New York City and L. J. Eastman becomes general manager of the Philadelphia Packard branch.

The territory which Mr. Silver will have is approximately the same as that which he has had during the last 6 years, taking in all New York City, Long Island, Staten Island, most of New Jersey and a part of Connecticut, with a branch in Bridgeport. He will also take care of the Atlantic seaboard on Chalmers parts.

C. T. Silver, Inc., as the new company will from now on be known, will handle 10 per cent of the Chalmers output, dating from Aug. 1, for the coming year. Business in Peerless, Chalmers, Overland and Willys-Knight cars is now going on in Silver's salesrooms. The last two will be on the floors until all sold, though the new Overland branch will probably take them over. The Silver organization has taken over the new Chalmers cars in stock at the former New York branch and a sale is being held on the second-hand machines.

Mr. Silver began his automobile career about 7 years ago, being first associated with the Koehler company in the sale of Buick cars in Manhattan. Then he went to the Buick branch in Brooklyn. Later he established an Overland agency in that city, after which one was established in New York City at Broadway and Forty-ninth Street. In 1914 he acquired possession of the Peerless Building, where he greatly enlarged his business with the Overland, Willys-Knight and Peerless.

The formation of the new Mitchell Motors Co. of New York is in keeping with the general Mitchell policy of expansion, the company planning to build 25,000 cars for 1917. Nearly 2000 Mitchell cars were sold in the metropolitan territory last year and it is hoped to double or treble this output next year. The new Mitchell Motors Co. of New York will have the entire metropolitan territory consisting of New York City, Brooklyn, Long Island, Staten Island, Westchester and Fairfield counties, including Bridgeport and three counties in New Jersey.

comparatively early date in order that the catalog and information for jobbers' catalogs may be placed in the hands of the jobbers by Oct. 1.

The conference was attended by Emil Grossman, president, who presided, Jos. N. Lowe, vice-president and Western representative; Lewis M. Crittsinger, vice-president and factory manager; Lewis M. Schwartz, secretary, who also acted as secretary of the meetings; Harry G. Wedler, Southern and Southwestern representative; W. M. Farans, Eastern representative; A. E. Rosenberg, Middle Western representative; M. S. Rosen, factory representative; Rudolph Cony, Chicago branch manager; F. B. Conner, purchasing agent, and Chas. Rottner, New York representative. A dinner followed the final conference.

Colt Is Cole Eastern Manager

NEW YORK CITY, July 17—W. L. Colt has been appointed eastern district sales manager of the Cole Motor Car Co. Mr. Colt will still retain the presidency of the Colt-Stratton Co., sole distributor in this territory. Capt. Harry Stratton will assume the duties of general manager.

Detail Improvements in Velie

Will Use Timken Axles—New Bodies in Seven Styles

MOLINE, ILL., July 15.—As far as the chassis is concerned the Velie "Biltwell" sixes for 1917, made by the Velie Motor Vehicle Co., this city, have undergone little alteration. Perhaps the most prominent mechanical alteration is the use of Timken axle equipment, though sundry little details have been improved, tending to enhance the value of the cars.

In the body line a good deal has been undertaken and one of the most striking of the new models is the four passenger roadster which is quite novel, having a sweeping side line running down to the rear deck. Internally there is all the accommodation of a four-passenger clover leaf of ample proportions and plenty of baggage space in the deck. This roadster sells for $1,085 as does the five-passenger touring body, which is also quite new, being both longer and wider than that fitted to the 1916 chassis. There is a two-seated roadster at $1,065, with a large amount of space for stowing baggage and a four-passenger coupé for $1,750. For special orders a range of other inclosed bodies is made, including a very neat little town job on distinctly French lines for $2,200, a touring sedan for $1,685 and a cabriolet roadster at $1,485. The manufacturers state that all these bodies are built very substantially and are upholstered in regular Velie style with the best quality of materials. All the bodies enumerated above fit the smaller chassis of 115-in. wheelbase. There is also a seven-passenger job on a larger chassis, this having a larger engine and a wheelbase of 124 in.

On both chassis the engines used are of Continental make, and both are sixes, the smaller 3¼ by 4½ in. and the larger 3½ by 5½ in. A taper frame is used.

Dry disk clutches are fitted to both cars, but the larger has a four-speed transmission while the smaller has three speeds only. The tubular driveshaft has a universal at each end, the long three-quarter springs taking both torque and drive.

Detroit Congress Plans Greater Sales Efficiency

(*Continued from page* 87)

on the Ethics of Salesmanship by the nation's leading executives. Monday morning, July 10, the formal opening in Arcadia Hall was addressed by President Woodrow Wilson; also by Secretary of Commerce William C. Redfield and Arthur Brisbane.

Monday afternoon there were further addresses on sales topics; Tuesday morning and afternoon general sales sessions were held in the Board of Commerce Building, which organization assisted in staging the convention.

Wednesday morning and afternoon departmental sessions were held in Hotels Statler and Pontchartrain, and that evening the visitors went for a boat ride on Lake St. Claire.

This morning the final session and the completion of the organization work was effected in the Majestic Theater and this afternoon the convention held a salesmanship circus at Bois Blanc, going by special boat.

Better trained sales managers were recognized as one of the industry's needs, in order that these men may become capable teachers of the salesmen under them.

Great applause followed every reference to a merchant marine, which was mentioned by President Wilson and Secretary Redfield. President C. Louis Allen of the Pyrene Mfg. Co., New York, struck a popular chord when he said the lack of popular support for a merchant marine was in part due to the failure of the ordinary man to appreciate what was meant. He said that the legislators and business men have been talking in the wrong language. "Everybody understands what is meant by freight car shortage," he said, "why not talk to them about 'ship shortage.' Then they'll know what is meant and will appreciate the value of a merchant marine."

Mr. Allen said the salesmen of the United States could become a power for the Government if their aid was enlisted in support of any desired propaganda such as that for a merchant marine. There are said to be more than 1,000,000 salesmen in this country.

Raising the standard of Sales Bulletins and making them of more practical value was advocated by V. L. Price, vice-president of the National Candy Co., St. Louis.

"Choosing men" was discussed by several speakers and a clinic at the Hotel Statler revealed the value of psychology in rating applicants for positions.

Among the industrial problems discussed were: "Selling Schools," Edward A. Woods, president, National Association of Life Underwriters, Pittsburgh; "Integrity," Frank Goeway Jones, Detroit; "Direction of Salesmen," M. B. Nelson, sales manager, Long Bell Lumber Co., Kansas City, Mo.; "Influence of Salesmen on Product," R. B. Goodman, Goodman Lumber Co., Goodman, Wis.; "Selling Schools for Manufacturers, R. H. Grant, sales manager, Domestic Engineering Co., Dayton, Ohio.; "Price Maintenance," George E. Watson, secretary, Southern Cypress Mfgr.'s Asso., New Orleans; "The Quota," F. H. Dodge, sales manager, Burroughs Adding Machine Co., Detroit; "Contests," Blaine S. Smith, sales manager, Universal Portland Cement Co., Chicago; "The Price-cutting Manufacturer," A. A. Breed, president, Crane & Breed Mfg. Co., Cincinnati; "Driving vs. Leading," Harry Tipper, the Texas Co., New York; "Making the Sale Produce a Profit," J. C. Walker, educational division, Burroughs Adding Machine Co., Detroit; "Salesmanship from the Standpoint of the Employer," Morris W. Ellis, Ellis Shoe Co., Nashville.

The selection of the next convention city was left to the executive committee, but an expression of sentiment by the convention seemed to favor Philadelphia, which was well represented by official spokesmen.

For their work before and during the convention Awards of Merit were given. These consisted of small diamond-set insignia for the lapel. The winners were Woodrow Wilson, Norval A. Hawkins, Hugh Chalmers, Harry M. Jewett, Lee Anderson, Harry W. Ford, D. M. Barrett, Joseph Mack, W. C. Standish and Walter C. Cole, the latter secretary of the Detroit Board of Commerce.

Kansas City Sales Gain 50%

Crops and Business Conditions Are Excellent—City Business a Feature

KANSAS CITY, MO., July 17—June was a record-breaking month in the automobile business in the Kansas City district. Branch houses, agencies and dealers report trade 25 to 50 per cent ahead of the same month last year, and the 6-month period to have shown a constantly increasing ratio of gain since Jan. 1.

"June has been 100 per cent better than any June in the past," said H. A. Clark, sales manager of the Missouri Haynes Co., covering Kansas, Oklahoma and half of Missouri. "The first 6 months of this year have been 50 per cent better than any previous first 6 months. More cars have been sold in the Winter and Spring months by 100 per cent than in previous years in this territory."

The gain is attributed to the constantly improving dealers' organization in the territory, Kansas and Missouri.

The Greenlease Motor Car Co., handling the Cadillac exclusively, in Northern Kansas and Western Missouri, also reports a 50 per cent increase in June, despite the handicap on the country business due to rains and floods. The gain was, therefore, chiefly in city trade.

Outlook Is Promising

There is a general expectation of increased trade for the future borne out in the report of the Federal reserve bank, for June. The rains that hindered sales, have brightened crop prospects for wheat, insect damage has not increased, and the total crop of Kansas looks nearer 100,000,000 bushels than 90,000,000, with the quality rather better than last year. The first alfalfa crops were heavy and of fine quality. There is an unprecedented stock of grain in storage. The corn has been seriously hindered in growth by wet weather—but hot days came just in time to give the crop growth. The labor situation is causing some uneasiness, both as to crop work and in the city, where strikes are holding up many buildings, some of them needed larger quarters for automobile and tire firms.

Kansas City's bank clearings gained nearly $230,000,000 for the first 5 months—a gain of $52,052,236 in June makes the total advantage of 1916, first 6 months, over 1915, $279,974,491. Postal receipts show a gain of well towards $200,000, for the 6-month period. The live stock industry is more prosperous for the time being than ever in its history, says the report of the Federal Reserve bank. Kansas City showed the largest gain in receipts, reports available later than that of the bank being that the gain was 30 per cent over June, 1915.

Bower Declares 15 per Cent Dividend

DETROIT, MICH., July 13—The directors of the Bower Roller Bearing Co., this city, met on Tuesday and declared a 15 per cent cash dividend as the regular quarterly dividend.

Material Prices Lower

NEW YORK CITY, July 17—Despite a shortage of raw materials for the manufacture of automobiles, prices are remaining for the most part unchanged or lower. The metals, especially, are lower, as is also rubber. The latter is now coming into this country in large lots.

Twenty carloads of crude rubber, a solid trainload, valued at $1,000,000, are on their way to this city from San Francisco via the Southern Pacific's Ogden route. This shipment, which came from Singapore, is the first consignment of rubber of such magnitude to go overland from the Pacific Coast. It was shipped here by the East Asiatic Co. on its steamer Bried. Exports of crude rubber to this country from Para, Manaos and Brazil, for the month of May, amounted to 5,693,929 lb.

The most important drop of the week in the metals was that of Bessemer Steel, which went down $2 per ton to $40 on Thursday.

$3,000,000 Capital for Portage

New Financing Plan Adopted at Meeting of Tire Concern Stockholders

AKRON, OHIO, July 13—A new plan of financing with an increased capitalization was adopted by stockholders of the Portage Rubber Co. meeting in Barberton on Tuesday. The present capitalization of $1,250,000, of which $500,000 is in common and $750,000 in preferred, will be increased to $3,000,000, placing $1,000,000 in preferred and $2,000,000 in common.

Of the preferred $250,000 will be offered to the present stockholders on a pro rata basis. The stockholders also voted to amend the constitution of the corporation so that the present issue of a million preferred may be convertible into common shares up to July 1, 1917.

A common dividend has been declared of 2 per cent, quarterly, payable Aug. 15 to stockholders of record Aug. 5.

One million of common will be set aside for exchange purposes. Common stock in the Portage corporation pays 8 per cent and the preferred 7 per cent.

Overland Declares 10% Stock Dividend

TOLEDO, OHIO, July 13—The directors of the Willys-Overland company yesterday declared a regular quarterly dividend of 3 per cent in cash, placing the regular dividend on a 12 per cent per annum basis. The directors also declared an extra stock dividend of 10 per cent.

The cash dividend is payable Aug. 1 to holders of record July 24. One half of the 10 per cent stock dividend is payable Oct. 2 to holders of record Sept. 15. The remainder is payable April 2 to holders of record March 15.

After the meeting President J. H. Willys stated that orders received last week for immediate shipment amounted to over 10,000 cars. Business was never better than at present. During the 6 months ended June 30, 1916, the number of cars sold and delivered was 94,477, being two and one-half times the shipments in the corresponding period of 1915.

Geiger-Jones Offering New Issue of Preferred

LIMA, OHIO, July 13—The Geiger-Jones Co., which controls the stock of the Gramm Motor Truck Co. of Lima is offering for sale a limited amount of the ne wissue of preferred 7 per cent cumulative stock at 101. The issue was

authorized at a meeting June 17 by more than 80 per cent of the stockholders of record.

In the statement issued with the call for stock subscriptions, the company is shown to have had profits of $579,000 in 1915 after making deductions for depreciation and other charges. In other words the profits were sufficient to pay the preferred dividends and 66.4 per cent on the common stock outstanding at the end of the year. The dividends on the preferred are payable quarterly, in January, April, July and October. The stock is non-taxable in Ohio. The business of the company in 1915 amounted to more than $4,000,000

—

Packard Motor Car Earnings Estimated at $6,050,000

DETROIT, MICH., July 17—The Packard Motor Car Co., this city, has just issued a statement of its earnings since 1909. The company that year earned $2,612,774 and it expects to earn for 1916 about $6,050,000.

The figures for the fiscal year of 1915-1916 contain a conservative estimate covering the last quarter of the year; and after paying regular preferred and common cash dividends and deducting the 10 per cent common stock dividend distributed Feb. 1, 1916, and the 50 per cent common stock dividend to be distributed Aug. 1, 1916, the balance in surplus account at the end of the year is expected to exceed $6,376,344. This is after deducting depreciation aggregating for 7 years more than $9,000,000.

Security Prices Lower

Chandler, General Motors, Chalmers and Firestone Stronger

NEW YORK CITY, July 18—Automobile securities on the New York Stock Exchange and the Curb were under attack yesterday by traders with a general decline. Overland went down 3 points, as did Maxwell, Chevrolet and Studebaker.

Some of the stocks, however, showed unusual strength, despite the bear attack. Firestone reached 915, or a gain of 35 points. This company has just issued a financial statement showing net gain in business of 38 per cent. General Motors, with a gain of 15 points for the week, was also strong. Chevrolet, however, which was subject to much selling during the week, dropped 34 points to 194.

The bearish action of the traders is unexplainable at the present time, as most of the companies are showing excellent earnings.

Initial transactions were made yesterday in the stock of the recently organized Mitchell Motors Co. The first sale was made at $67.50. Subsequently there was an advance to $68, followed by a 2-point decline.

—

$5,000,000 Earnings for Canadian Ford

WALKERVILLE, ONT., July 15—The net earnings of the Ford Motor Co. of Canada, Ltd., for the current fiscal year of 10 months, ending July 31, show approximately $5,000,000, which would be equivalent to about $70 a share on the $7,000,000 outstanding capital. From these earnings, however, will be deducted the Canadian war tax.

The company has spent $2,750,000 in erecting four new assembling plants and other extensions to the Ford, Ont., plant, which additions give 162,000 sq. ft. more floorspace.

The new Canadian assembling plants are located at Montreal, Toronto, London, and Winnipeg.

Crawford	Lewis.	31.37.10	94.89	300

OMAHA, NEB., July 15—Under the hottest sun that has shone on a race in many years, Dario Resta drove his blue Peugeot to victory in Omaha's second annual automobile derby, nosing out Mulford, who had been looked upon as a likely winner until almost the end of the race. His time for the 150 miles was 1:30:43, an average of 99.02 m.p.h., a record for 150 miles on a 1¼-mile track. Mulford finished 1 min. and 13 sec. later, averaging 98.39 m.p.h. He also won the $100 prize for the fastest lap.

Don Columbo, mechanic for Franchi in the Peusun, was killed when they went through the safety wall in front of the grandstand.

Resta jumped into the lead in the first lap but was crowded close by Mulford and Rickenbacher, Mulford heading Dario before ten laps were made. The Omaha track has not stood up as one would expect. The 2 by 4's have split and there are many ruts, some as much as 2 in. deep.

On his tenth lap Franchi tore down the homestretch at 100 m.p.h. or more. Immediately in front of the pits he struck the ruts in the track, the front of his car swerved toward the grand stand, he tried to right it, then the rear end turned clear around and the whole car hit the wall broadside, tearing down 100 ft. of the wall and dropping 15 ft. into the space between the track and the grandstand. Had the car been stood on one end and a pile driver put on the other the damage to it hardly could have been worse. At a casual glance it was hard to tell the front from the rear, so badly was it damaged.

Flying planks and splinters injured a few slightly in the stands and the track was literally covered. The course was exceedingly dangerous for the other drivers but the debris was cleared away between the passing of cars.

At 20 miles Mulford led, Resta was second, Rickenbacher third, Gable fourth and Chandler fifth. The toll on tires was terrific. Mulford was forced to stop many times toward the end of the race, when seconds counted. Many of his changes were made in 20 to 25 sec.

Resta led at the end of the first hour, his speed being 101.37 m. p. h. He and Milton were the only ones who made no tire changes.

In the seventy-sixth lap Jack Gable drove the Burman Special, the same car in which Burman was killed at Corona last April and which is being campaigned for Burman's widow, through the fence and into the infield. The car turned over three times, but Gable and his mechanic, Harry McGraff, were thrown out on the first impact and escaped with a few bruises.

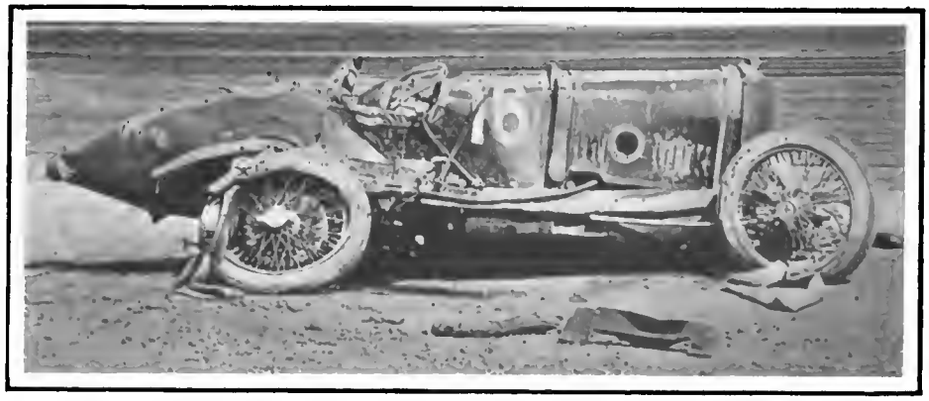
Before the race Mulford refused to let the Hudson Super-six go in. This left Vail without a mount, but Ralph finally was won over and Vail took the car. His ignition wires caught fire once, he changed mechanics once when his first mechanic was overcome by the heat, and then Vail used up all the tires he had and had to withdraw.

Rickenbacher went out at 101 miles with valve trouble. He was in third place at that time. De Palma was forced to withdraw soon after Rickenbacher came in, Ralph's trouble being a broken valve cap.

Seven Running at Finish

Only seven of the seventeen cars that started were running at the finish. They were Resta, Mulford, Milton, Kline, Muller, Henderson and Stringer.

In the 50-mile free-for-all that followed 30 min. after the finish of the big race, seven cars started, De Palma heading them all and winning at a speed of 103.45 m. p. h., his time being 29:2.47. Rickenbacher was second, Henderson third, Lewis fourth, Stringer fifth, Milton sixth and Rawlings' Duluth Special went out in the twenty-third lap with a



Wrecked Burman special, which turned over three times without injuring Gable or his mechanic. Bob Burman lost his life in this car at Corona in April

broken crankcase. Mulford's Hudson withdrew at the end of twenty-four laps with a burned-out bearing.

De Palma took the lead at the start of the race and showed much speed to the end. Rickenbacher put up a game fight but the Mercedes had plenty of reserve speed and held its own.

15,000 Spectators

About 15,000 people witnessed the races. The infield was thick with cars and the prejudice which resulted from the meager field of last year, when the date given Omaha was one day following Sioux City, where several cars were put out of the running to the disappointment of Omaha, was not in evidence today. Many predicted a repeat victory for Rickenbacher, but he did not make good.

The qualifying speeds of the different cars were exceedingly high. Ten of them were over 101 miles per hour.

Nearly every driver was exhausted from the excessive heat which registered over 104 deg. all afternoon. Resta could speak only with difficulty when he was helped from his car. The track was as hot as a stove and the pitch boiled out of it.

Resta's Big Lead

Winning to-day's race gives Resta 2,400 points toward the speedway championship and the $13,500 in money and a cup offered by Goodrich and Bosch. His lead is fairly safe at this time. De Palma would have headed Resta had he won to-day's race. To date he has made 1670 points with Rickenbacher third with 770 points.

The exact standing of competitors follows:

Driver	Points	Driver	Points
Dario Resta.	2400	C. J. Devlin.	90
R. De Palma.	1670	B. Oldfield	80
Rickenbacher.	770	Mel Stringer	55
Ralph Mulford.	595	George Adams.	55

Elgin Road Race Postponed

Chicago Speedway May Get Aug. 19 for American Speedway Grand Prize

CHICAGO, ILL., July 17—Now that the Elgin road races for this year have been called off, it is practically certain that racing fans of the Central West will have an opportunity to experience the thrills of speed on the date set for the Elgin road races, Aug. 19. David F. Reid, president of the Speedway Park Assn., has wired to the American Automobile Assn. contest board for the Elgin date when the local speedway will stage the American Speedway Grand Prize, and it is practically certain that the request will be granted as such a promise is said to have been made by the contest board in case the Elgin races did not materialize.

A gold cup already has been ordered for the American Speedway grand prize and the entry blanks which have been printed will be sent out this week. Cars to qualify must average 100 m.p.h. or better, and the prize money will total $10,000 divided as follows: $5,000 for first, $2,500 for second, $1,250 for third, $750 for fourth and $500 for fifth. The conditions of the race are an innovation in speedway competition. Five heats, 20 miles each, and a 50-mile final will be run. The winner of each heat will qualify for the final and as soon as a driver wins a heat he steps aside, being assured a piece of the prize money even though he does not start in the final, since there are five prizes and cannot be more than five to start in the final dash. The cup will have to be defended each year.

Plans are under way for putting on a contest for the Elgin National Cup on the day following the American Speedway grand prize, but whether or not this will be done is a matter of conjecture at this time.

—

Fourteen Tacoma Entries to Date

TACOMA, WASH., July 14—The Tacoma Montamarathon race to be held Aug. 5 on the Tacoma Speedway will be for a distance of 300 miles, with a purse of $10,000 for the one event.

The track has already been placed in the best possible condition, a new guard rail completed for the entire course.

Entries are now coming in, and those who have signed blanks to date, are as follows:

Driver	Car
Rawlings.	West-Duluth
Chandler.	Crawford
Lewis	Crawford
Johnston	Crawford
D'Alene	Duesenberg
Milton.	Duesenberg
Unnamed.	Duesenberg
Devigne	Delage
Franchi	Delage
Moore	Hudson
Duray	Omar
Barsby	Hudson
Rickenbacher	Maxwell
Henderson	Maxwell

To Enlarge Dodge Bros. Club

DETROIT, MICH., July 16—It has been intimated by John F. and H. E. Dodge that a new building is soon to be erected for the benefit of Dodge Brothers' Recreation Club, where the club may broaden the scope of its work and provide a permanent source of recreation for Dodge Brothers' workmen.

Factory Miscellany

To Make Exhaust Heater—David Reyam of Wilmington, Del., has invented and had patented a device for using automobile engine exhaust in heating the car space used by occupants in winter. While it can be applied in various ways, the chief thought is to heat the entire interior of a closed car, while in cars that are not entirely enclosed, the source of heat is to be at the feet of the occupants, coming up under blankets or such other covering as they may have for protecting their limbs from the cold.

The device does not take the direct heat of the exhaust, but has it passing between coils containing air, which, after being heated, is discharged in the car at the points desired. It is claimed to be so adjustable that the temperature can be regulated to any heat desired, also that the heat can be quickly generated.

It is the intention, Mr. Reyam says, to manufacture the device in Wilmington. He says it is economical in cost and maintenance and is durable.

Stafford Still Making Parts—The Stafford Motor Car Co., Kansas City, Mo., which in 4 years made 500 cars, ceasing manufacture 2 years ago, continues to make parts, at its factory; the plant, however, is chiefly occupied with a large volume of repair work for all kinds of cars, the calls upon the equipment being largely in excess of the capacity.

Tire Plant for South Bend—South Bend, Ind., is to have a new tire plant. The International India Rubber Corp., incorporated last fall for $1,000,000, is to erect the plant, in which tires and tubes will be manufactured. P. E. Studebaker is president of the company, and the other officers are: Vice-President, E. H. Schwab; treasurer, T. W. Slick; secretary, G. W. Odell. The company is establishing branches in various parts of the country.

Chevrolet Assembling Plant in S. W.—The Chevrolet Motor Co. of Texas, Fort Worth, will build an assembling plant. The site which has been under consideration for several months is a 7-acre tract west of Trinity Park and south of the Arlington Heights Boulevard. The building plans provide for a structure of three stories, the foundation of the building measuring 275 by 375 ft.

Splitdorf Engine Co. Formed—The Splitdorf Engine Co., Augusta, Me., has been incorporated to deal in motors and generators, with a $200,000 capital, by R. S. Buzzell, president; L. J. Coleman, treasurer, and C. L. Andrews.

200 Canadian Fords a Day—Production of the Ford Motor Co. of Canada is now running at the rate of 200 cars a day and plans are under way to increase the daily output to 250 cars in the next few months.

From Oct. 1, 1915, to the middle of June, this year, the company produced 31,500 cars. The current fiscal period will include only 10 months, as the company's year has been changed to begin Aug. 1 instead of October. Next year's production is estimated at 60,000 cars.

The company has spent about $2,750,000 in erecting four new assembling plants, extensions to the Ford, Ont., plant, additions to the power plant at that place, a new machine shop, office buildings and installation of new machinery.

Auto Body to Increase Force—The Auto Body Co., Lansing, Mich., which now has about 750 men on its payroll, expects to employ at least 1400 within the next 30 days, when additions to the plant will be completed.

The working force of the Gier Pressed Steel Co., this city, is to be increased from 500 to about 750.

Hester Tire to Build—Three acres of land, lying between the C. H. & D. tracks and Jefferson Avenue, Lima, Ohio, have been obtained by the Chamber of Commerce as a site of the new factory to be built by the Hester Tire & Rubber Co. Plans for the main factory building, 60 by 150 ft., and a power house, 60 ft. sq., are nearing completion. According to the company officials work will be started on the buildings within a short time and machinery will be installed before early fall.

The Hester Tire & Rubber Co. is a $100,000 concern, incorporated under the laws of Delaware and at present doing a general rubber jobbing business. One hundred men and girls will be employed at the start, and the force will be increased later, it is said.

Stromberg Under New Control

Allan A. Ryan and Banking Syndicate Charter New Company

ALBANY, N. Y., July 22.—A charter has been granted to the Stromberg Carburetor Co. of America, under the control of Allan A. Ryan & Co., and a syndicate of prominent banking interests in New York City, which recently incorporated the Stutz Motor Car Co. The directorate of the new company includes William Rand, E. F. Meniken and K. R. Howard, the first two being connected with the law firm of Jerome, Rand & Kresel, 37 Wall Street, New York City.

The company has issued 50,000 shares of no par value and will do business with $250,000.

The stock has been listed on the New York City curb and was traded last Thursday on a "when issued" basis. On the turnover of 1500 shares in this issue all but 100 shares changed hands at the subscription price of 42. Before the close of trading it was announced that the stock had been oversubscribed.

—

Hall Resigns from Olds

LANSING, MICH., July 22—J. B. Hall, sales manager of the Olds Motor Works, this city, has resigned. Mr. Hall has conducted the selling of Oldsmobiles for a number of years and is a well known figure in the industry. His future plans have not been announced, nor has his successor yet been appointed.

—

Baker Visits United States

NEW YORK CITY, July 22—Fred W. Baker of the Baker Rim Co., Ltd., Stourbridge, England, manufacturer of the Rebak rim for automobile wheels, arrived on the Baltic to-day and expects to spend a month in this country investigating the automobile rim business. Mr. Baker has made several previous trips to this country visiting our automobile shows.

—

Waldon Resigns from Cadillac

DETROIT, MICH., July 24—Sydney D. Waldon, vice-president in charge of engineering of the Cadillac Motor Car Co., has resigned. His future plans are not given out but it is not believed that he will again enter the automobile industry actively. Mr. Waldon has had a wide experience in the automobile business, relinquishing his position as vice-president of the Packard Motor Car Co. to go to the Cadillac company about a year and a half ago.

—

Hinckley Heads Chalmers Production

DETROIT, MICH., July 22—Following the resignation of S. H. Humphrey, as production manager of the Chalmers Motor Co., C. C. Hinckley, chief engineer of the company, has taken over the production department in addition to directing the engineering work of the company.

—

Hackett Four at Under $1,000

JACKSON, MICH., July 21—Following the change in name of the Argo Motor Co., Inc., to the Hackett Motor Car Co., as reported last week in THE AUTOMOBILE, comes the announcement of a new model to be known as the Hackett four. While none of the details have been made public, it is stated that the car is built to look like a speed boat and is sturdy of construction, light in weight and beautiful in design. The price will be under $1,000.

—

200,000 Cars in Illinois

SPRINGFIELD, ILL., July 22—The 200,000 mark has been passed in car registrations in Illinois.

French Makers Plan Cheap Cars

$50,000,000 Company Being Formed to Produce These in Quantity

PARIS, July 12—There are indications that immediately after the war some of the leading French automobile manufacturers will endeavor to get into the low-priced car trade and produce an automobile for the European and Colonial markets capable of competing with Ford on a price basis. Arrangements are in hand for the formation of a $50,000,000 company at Lyons to produce cheap cars only. It is declared that Renault and Berliet, two of the leading automobile manufacturers of France are interested in this concern. A Lyons body builder is interested in the body section of the new factory and is about to visit America for the purpose of getting information and arranging for the purchase of machinery for producing bodies on a big scale.

Popular report credits other manufacturers with the intention of going into the cheap car business. Among the names mentioned is an important firm which had specialized in gearcutting before the war and has since increased its staff from 3000 to 15,000. Factory development during the war has been phenomenal. One typical case is that of a well-known manufacturer who just before the war completed a new factory and laid plans for additions to be added during a period of 15 years. In the 2 years of the war he has attained the maximum he hoped to reach in 15 years and has had to buy new ground. As all French automobile and kindred factories have increased since the war from 30 to 300 per cent, there is an impression that the possible output of cars will be

considerably above the demands unless fresh ground is struck. There is a great danger of over-production when the new munition factories return to their ordinary work, and in some cases arrangements are being made to abandon automobiles for other branches of engineering. Marine engines, particularly Diesel type, are looked upon as a good field, and are said to be attracting some automobile manufacturers.

Ford's European Plants

The French Ford Co. has purchased land at Bordeaux on which to build an erecting factory, knock-down chassis from the Detroit factory will be assembled here as soon as possible. It is well known, however, that Ford has secured a big tract of land at Southampton where all cars for the European market will be produced. The English factory will then supply Bordeaux with units, and the Ford will enter France as a British car.

—

Suit Against Faw Dismissed

NEW YORK CITY, July 24—A patent infringement suit for a bulb reflector, brought by Nelson J. Quinn against J. H. Faw, Inc., has been dismissed in the United States District Court. The patent is No. 1,099,715. The construction in question is that of half the bulb being covered by a silver coating. The Faw device is a detachable metal covering, and not a coating upon the glass. The element of adjustability also entered into the question.

—

Fire in Gibson Plant

INDIANAPOLIS, IND., July 22—Fire which was caused by defective electrical wiring last night burned out the third floor of the Gibson Co.'s plant. This contained motor car parts and some accessory stock. The loss is approximately $85,000. Business, however, was not at all delayed. The company opened as usual this morning, adjusted itself to conditions, and its service system continued to operate as usual. Manufacturers assisted the jobbing company greatly by expressing a duplicate of the stock that was damaged, and this, with the reserve stock in warehouses, served to overcome the difficulty.

—

Sells Out Ziola Carbureter

MADISON, WIS., July 24—Henry A. Ziola, Madison, Wis., an inventor of electrical and carbureting devices for internal combustion engines, has sold all rights to the Ziola kerosene carbureter to a syndicate of St. Louis capitalists, headed by James B. Lloyd. It is said that Ziola received $30,000 for his patents. He is the inventor of an X-ray machine now being manufactured at Madison.

Europe Establishes Standards

—

England Has Standard Truck Design—Cars and Aviation Engines Affected

LONDON, July 12—Automobile standardization has been developed to such a degree that England is now prepared to produce a single type of truck in all factories for the use of her own and allied armies. Drawings and jigs will be supplied by the central authority to all the factories required to build trucks, and these factories will be obliged to build to this design, to the exclusion of their own models. A big series will go through immediately, and, it is declared, the output will be so great there will be no further need for American trucks.

The new design is a 3 to 4 ton model with four-cylinder engine of 5 by 6 in. bore and stroke. It has a four-speed gearbox and final drive by overhead worm. Hotchkiss drive is not incorporated. Ignition by high-tension magneto only is fitted; it is no longer considered necessary to have a secondary ignition by batteries. All-metal wheels are employed, both of the cast steel and pressed steel types. It has been necessary to adopt the two types on account of the big output contemplated.

Nothing Freakish in Design

In designing this truck everything freakish has been avoided and only features which have proved satisfactory under actual war conditions have been incorporated. The 5 by 6-in. four-cylinder engine gives a bigger piston displacement than is usually considered necessary for a 3 to 4-ton load under either English or French conditions. It is intended, however, that the new truck shall be as suitable for Russian service as for work on the French front, hence the more powerful engine. The design has been developed by an engineer who has had experience of all makes and who has enjoyed exceptional opportunities of observing the defects of trucks under war conditions. Obviously engineers with vested interests find much to criticize in the new design, but the authorities override all their objections and insist on everybody producing the one type of truck.

Standardization has not been confined to trucks. One firm having been very successful on aviation engines has been ordered to devote the whole of its plant to the production of these engines and to hand its touring car drawings and jigs to a rival firm of lesser importance. Such a course does not meet with the approval of the more important firm, for it is obliged to give away all its secrets to a concern which will be a rival after the war.

Germany has also realized the advantage of standardization. For a considerable time now she has specialized on two types of aviation motors, Mercedes and Benz, built in every available factory. In each case the motors are six-cylinder vertical water-cooled with valves in the head. The only exception to this scheme is the Oberursel, a copy of the French Gnome, used on Fokker scout machines.

German water-cooled aviation engines Mercedes and Benz, are all fitted with an indicator by means of which the pilot can ascertain the temperature of the cooling water. The Daimler-Mercedes Co. states that the maximum temperature of the water at the outlet from the cylinders should be 75 deg. Ordinary thermometers have not been found satisfactory and use is now being made of an electric telethermometer made by Hartmann & Braun, of Frankfort-on-Main. The apparatus consists of a metal piece immersed in the cooling water, and within this piece a spiral receptor of the temperature. Just in front of the pilot's seat is a galvanometric indicator connected to the temperature receptor by a suitable wire cable. The needle and the scale of the galvanometer are very clearly marked, the apparatus is entirely automatic and is not influenced by vibration.

Current is obtained from a small storage battery or from dry cells with interrupter. The thermometer portion of the appliance consists of a platinum spiral within a metallic armature. The apparatus is based on the principle of the ohmmeter. A water temperature indicator has proved of immense value in the aviation service. A large number of accidents have been traced to overheating which was not observable by the pilot until too late. Such an instrument is particularly valuable in the case of planes with more than one engine.

McComb Resigns from G. V.

NEW YORK CITY, July 22—H. C. McComb has resigned as engineer of the General Vehicle Co., Long Island City, to take up other engineering work and has opened offices at 1414 Times Building, this city.

—

N. A. C. C. Meets at Christmas Cove

CHRISTMAS COVE, ME., July 25—Officers and directors of the National Automobile Chamber of Commerce, Inc., are enjoying their annual sojourn here as the guests of Samuel A. Miles. The chamber is holding its summer meeting here as usual, business at the directors' meeting held to-day being mostly of a routine nature, although plans for the national automobile shows were discussed

and various schemes for decoration, etc., talked over. The patent situation also came in for a share of attention.

The party is combining pleasure with business, holding fish fries, clam bakes and general sports.

The directors and guests in attendance included President Charles Clifton, C. C. Hanch, H. H. Rice, John N. Willys, Wm. E. Metzger, J. Walter Drake, Windsor T. White, George Pope, H. M. Swetland, Alfred Reeves, Thomas Henderson, S. A. Miles, Charles E. Thompson, Wm. M. Sweet, John C. Wetmore, A. G. Batchelder, Thomas J. Wetzel, R. D. Garden, Charles Thaddeus Terry and Frank R. Nickerson.

—

Alvord Succeeds Hendee

NEW YORK CITY, July 26—J. F. Alvord, head of the Torrington Co., has succeeded George Hendee as president of the Hendee Mfg. Co., motorcycle manufacturer in Springfield, Mass.

—

Sulzberger Changes Name to Wilson

CHICAGO, ILL., July 20—Sulzberger & Sons Co., this city, maker of curled hair for automobile upholstery, has changed its name to Wilson & Co.

—

Newton Joins Hollier Maker

JACKSON, MICH., July 20—F. L. Newton, assistant sales manager of the Jackson Automobile Co. for the past 5 years, has resigned to become general sales manager for the Lewis Spring & Axle Co., Chelsea, Mich., manufacturer of the Hollier eight.

—

Pennington Joins Brunswick-Balke

MUSKEGON, MICH., July 25—A. J. Pennington, who for 6 years was general superintendent of the Lee Tire & Rubber Co., of Conshohocton, Pa., has been made factory superintendent of the Brunswick-Balke plant at Muskegon according to an announcement made yesterday by J. E. Duffield, sales manager of the new tire concern. He will assume charge of the Brunswicke-Balke plants on Aug. 1.

Brunswick-Balke will triple the output of tubes and casings originally planned.

—

McBride and Conlon Promoted

DETROIT, MICH., July 22—V. K. McBride, who has been in the sales department of the Federal Motor Truck Co. for over 2 years, has been appointed assistant sales manager of the company. H. A. Conlon, formerly a special sales representative of the Federal company in England, has been promoted to the position of field sales manager.

—

Acme Joint to Build

KALAMAZOO, MICH., June 20—A new factory building, 76 by 201 ft., will be erected for the Acme Universal Joint Co., which will cost about $20,000.

Kelsey and Herbert in Merger

Form Kelsey Wheel Co., with $13,000,000 Capital—John Kelsey President

DETROIT, MICH., July 22—The consolidation of the Kelsey Wheel Co., with plants at Detroit and Memphis, Tenn.; the Kelsey Wheel Co. of Windsor, Ont., and the Herbert Mfg. Co., Detroit, practically has been completed, the new corporation to be known as the Kelsey Wheel Co., Inc., with a capital stock of $13,000,000, composed of $3,000,000 of 7 per cent accumulative preferred stock and $10,000,000 of common stock.

John Kelsey is to become president of the new corporation, but the rest of the officers have not yet been determined. Control of the new organization will remain with Mr. Kelsey and associates.

Few realize the magnitude of the Kelsey interests, both here and in the South. At the main Kelsey plant in this city, twenty-five sets of wood wheels are produced daily, complete with rims. In the making of automobile rims the Kelsey company now ranks at the top and utilizes 150 tons of steel per day for this product alone. The Herbert Mfg. Co. makes 500 automobile bodies per day, besides finishing and trimming a large proportion of them. This plant is also a very large producer of a variety of steel stampings required in the manufacture of motor vehicles. The Memphis, Tenn. plant of the Kelsey company represents an investment of $500,000 and is the factory at which the hickory used in the manufacture of the wheels is concentrated. It is here worked into spokes and felloes, the completed wood wheels then being sent to Detroit where they receive their steel rims. The Kelsey company located in Windsor, Ont., is a separate corporation, but includes most of the same stockholders. It is the Canadian car manufacturers' main source of wheel supply. The Detroit Kelsey company has an authorized capital stock of $1,500,000, all of one class, and $900,000 of this is outstanding.

The preferred stock of the Kelsey combination is underwritten by Sachs, Goldman & Co., New York bankers, and the common is said to have been oversubscribed. In the organization plan their is provision for retiring to preferred stock at the rate of $90,000 per year. It is proposed to make the consolidation effective from Jan. 1, 1917.

—

Falls Machine Under New Control

MILWAUKEE, WIS., July 22—A well-defined report from Sheboygan Falls, Wis., says that the Falls Machine Co., Sheboygan Falls, manufacturer of small, high-speed gasoline engines for car builders, has passed into the control of a syndicate represented by Andrews & Co., bankers, Chicago. It is stated further that the company will be reincorporated as the Falls Motors Co., under the laws of Virginia, with a capital stock of $1,500,000. The company has made extensive additions during the last 8 or 10 months and at this time is still further enlarging the capacity. One of its largest contracts is that for all motors for the Grant Six.

—

Ferguson Resigns from G. M.

DETROIT, MICH., July 20—D. M. Ferguson has resigned as consulting engineer for the General Motors Co., and his plans have not been announced. Previous to his connection with the General Motors, Mr. Ferguson was chief engineer for the Studebaker Corp.

—

Walker Becomes a Chandler Engineer

CLEVELAND, OHIO, July 24—Hiram Walker has been appointed assistant engineer of the Chandler Motor Car Co., this city. He was previously connected with the Enger Motor Car Co., Cincinnati, Ohio, in the same capacity.

—

Moss Joins Thomas Truck

NEW YORK CITY, July 26—J. L. Moss, M. E., has resigned as designing engineer of the International Motors Co., and has joined the Thomas Auto Truck Co., this city, as chief engineer.

—

Jehle with Aluminum Castings Co.

CLEVELAND, OHIO, July 22—Ferdinand Jehle has resigned as laboratory engineer of the Automobile Club of America, New York City, to assume the position of service engineer with the Aluminum Castings Co., this city.

—

Horning and McKinley Councillors

NEW YORK CITY, July 24—In the list of new S. A. E. nominations giving the officers of the coming year there appear the names of Harry L. Horning, Waukesha Motor Co., and Charles W. McKinley, Willys-Overland company, who are nominated as councillors to serve for 2 years.

—

Martin, Burd Ring V.-P., Retires

ROCKFORD, ILL., July 22—A. A. Martin, vice-president and sales manager of the Burd High Compression Ring Co., this city, and who organized this company, will retire from that concern Aug. 1.

—

France Orders 600 Moreland Trucks

LOS ANGELES, CAL., July 20—W. L. Moreland, manager of the Moreland Motor Truck Co.'s factory, this city, announced to-day that the War Department of the French Republic had cabled an order for 600 Moreland trucks.

South America

U. S. A. Cars Selling Well in Country—Big Gains in Last Year

Argentine Farmer Shown Our Cars Can Stand Up Where Roads Are Poor—European Car Business at Standstill

By David Beecroft

MEDIUM and low-priced U. S. A. cars are selling in Argentina, in parts of Brazil, in Uruguay and Chile in steadily increasing quantities. This selling movement started approximately 1 year to 18 months ago at a time it was least expected that U. S. A. cars would sell. The war had started, in general South American finances were in a deplorably bad condition, as such European countries as England, Germany, France, Italy and Belgium had stopped supplying the money that they had been supplying for 45 to 55 years. Further: It was at a time when these countries were in the second or middle stages of a financial crisis that started 2 years before the war, to be exact, in 1911, and which was only augmented because of the war.

A still further fact with regard to the starting of sales of U. S. A. cars was that it began at a time when every dealer in European cars had his salesroom and warehouse filled with European machines which had practically ceased to sell. The sale of expensive European cars stopped practically 4 years ago, and there are many salesrooms to-day filled with the cars they contained then. With the cheaper European cars it has been different: They have sold, but none has arrived to take their place since the war started, with the exception of Italian cars which were shipped in large quantities from the opening of the war until 1 year ago, when Italy became embroiled in the struggle and had need for all her machines in her own land.

Within the last 2 years the entire attitude of Argentina, parts of Brazil, Uruguay and Chile, and it may be other countries in South America, have changed toward the low and medium-priced U. S. A. cars. True, before that time we had sold cars in Argentina and Brazil. We have had agencies of U. S. A. cars continuously in Buenos Aires for 14 years. One dealer has had the Cadillac continuously for that time. Scores of our different makes of all prices are there, but with few exceptions they were not popular and did not sell on a scale to be compared with cars from France, Germany, England, Italy and Belgium.

Europe had the market almost entirely within its own grip. France, Germany, England, Italy and Belgium seized the market 15 years ago. When we were running our first Vanderbilt Cup race in Long Island these countries had already invaded Argentina and Brazil and such cities as Buenos Aires, Rosario, Cordoba, Mendoza and Tucuman had already learned of the automobile. Buenos Aires shows in its ancient cars older European machines than can be found in U. S. A. I visited one dealer's museum of automobile antiques to see a Benz made before the front axle was used, each front wheel being carried in a huge bicycle type of front fork. There are old Mercedes of nearly the same vintage, and very ancient Panhards, De Dions, Renaults, etc. Europe, for one reason or another, was earlier with its cars in South America than in the U. S. A. Perhaps this was due to the large investment of capital in these South American lands and the controlling interest that European capitalists had in nearly all of the large public utilities such as railroads, trolley systems, telephones, telegraph, factories, etc. Gen-

South American Series

THIS is the first of a series of articles on South America that will appear from week to week in THE AUTOMOBILE. *David Beecroft, Directing Editor of* THE AUTOMOBILE, *has just returned from a 3 months' trip through Argentina, Uruguay, and Southeastern Brazil, where he studied automobile conditions. Mr. Beecroft went as a member of a United States Government committee appointed for the purpose of developing more friendly trade relations between South American countries and the United States.*

While in South America he traveled extensively through the different countries, visited a majority of the concerns interested in the sale of automobiles and accessories, and made a comprehensive study of the possibilities of wider use of American automobiles, accessories, motor trucks, and farm tractors in these three countries of South America.

Additional articles will appear from week to week, taking up in detail the different factors entering into South American trade.

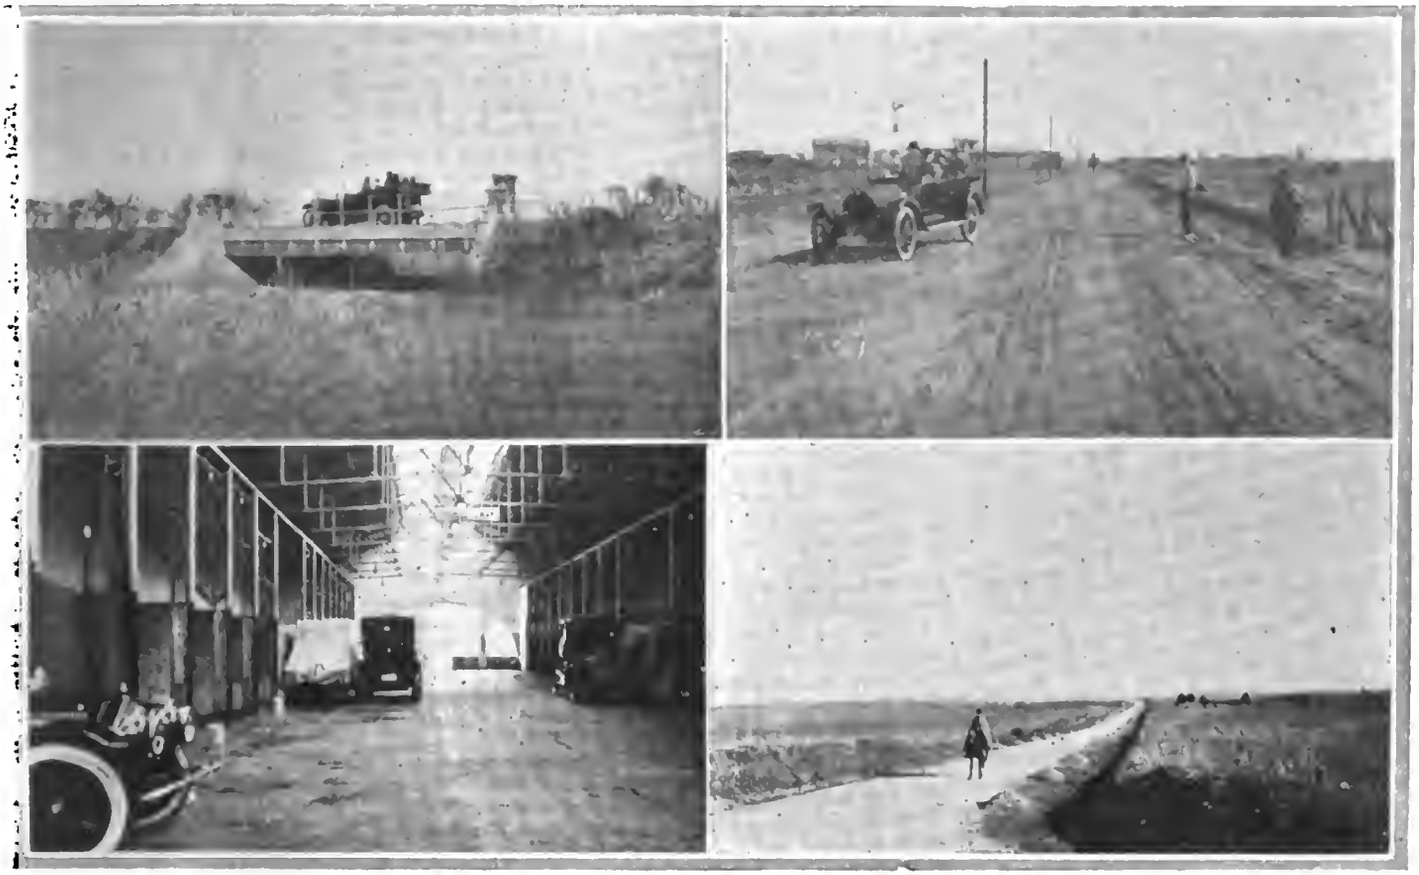
IF your conception of South America is from the maps you saw in your public school geographics, it will be well to revamp such. South America is not quite so large as North America but it has one country, namely, Brazil, which in area is about the same as the U. S. A. when Alaska is left out. Brazil, U. S. A., Canada, Australia and Europe are all about the same size, namely a little over 3,000,000 square miles. Keep in mind that Brazil is a huge country, and there they speak of the United States of Brazil just as we speak of the United States of America.

Argentina is smaller in area, but approximately the same as that of the U. S. A. east of the Mississippi River. At present Argentina and Brazil are the great possible market for U. S. A. cars, and the smaller countries like Chile and Uruguay are taking them in goodly quantities. In the other countries the advent will be slower as social and physical conditions are not so favorable. The east coast is naturally a more attractive selling field than the west coast, which is very narrow and generally hemmed in between the lofty Andes Mountains and the sea. There is a 2000-mile stretch on the west coast which is practically rainless. Immediately in from the west coast the land is from 10,000 to 12,000 ft. above sea level and, naturally, this high altitude has held back European settlement much more than in the great agricultural and grazing territories along the east coast.

Scenes of Country and City in South America

Typical landscape in Argentine farming and grazing country where U. S. A. low and medium-priced cars are selling so well at present. The country is level and very fertile. Argentine is one of the greatest stock raising countries in the world

Upper left—Street scene in Sao Paulo, Brazil, a city of 500,000 population, showing taxicabs lined up in center of street. The cabs are well distributed all over the business section of the city. They are all European, Berliet and Fiat being leaders
Upper right—Argentine has few roads. Here is a new stone block one 60 miles in length between Buenos Aires and the City of La Plata. This city is very modern, is a growing port and is capital of the Province of Buenos Aires. Armour and Swift packing plants are located in La Plata
Lower left—The heavy stone foundation used in the Buenos Aires-La Plata road, which was built by a French engineering company and will be completed in August, 1916, the work being rapidly advanced toward completion throughout its length
Lower right—A passenger dock in Buenos Aires for river traffic. Note wide, well-paved areas around the dock. This is general throughout the city, which in many other respects exhibits up-to-date characteristics and applications of modern ideas just as found in many cities in the U. S. A.



Upper left—Typical concrete and brick bridge on Buenos Aires-La Plata road. There are nearly two dozen of these very modern bridges in the 63 miles

Upper right—graded section of Buenos Aires to La Plata road ready for stone foundation on top of which is laid the stone block surface

Lower left—Type of public garage in Buenos Aires with individuat stalls for cars. Each car is literally in a separate garage of its own

Lower right—Type of new national roads being built in Uruguay, one of the smallest countries in South America. Nearly 130 miles of this road has been built in one stretch and short stretches in other places. In 2 years a road of this character will span the country from Montevideo to the Brazilian boundary on the north. Roads such as these should prove marvelously efficacious as educational aids to dealers in U. S. A. cars in their efforts to render these cars popular in South America and the roads movement is rapidly growing stronger

***Typical** view of the country in Uruguay where U. S. A. low and medium priced cars are selling in goodly numbers. The country has very few roads and not enough bridges, but the government has planned a large road scheme and much progress has been made in the tast 2 or 3 years*

One of several examples of the high-class bridge construction being used on the new motor roads in Uruguay. This country is very ambitious in its road problems and hopes to make its roads the greatest touring fields of South America

erally England and Germany had their largest manufacturing interests of all kinds largely represented in South America and when the automobile started coming into prominence it did not require much extra effort to market the car, as they were generally sold by large houses that handled myriad lines of machinery either electrical, hydraulic, agricultural, mining or other kinds.

Progress from 1900 to 1911

Before going further into the present rapidly increasing sale of U. S. A. cars in South America look for one moment at the progress made from 1900 to 1911, when the financial crisis arrived, in the sale of European cars. To-day in Buenos Aires, Rosario, Cordoba, Bahia Blanca and other Argentina cities, in Montevideo, in Uruguay, and in Rio de Janeiro, Santos and Sao Paulo, in Brazil, you see thousands of all makes of European cars in use, the most expensive makes generally in greater quantities than the cheaper ones.

Buenos Aires has finer European cars than New York, Boston, Philadelphia and Baltimore. You see every known French, German, Italian, Belgian and very many English makes in all the cities mentioned. There are scores of makes scarcely heard of and rarely if ever seen in the U. S. A. Take Italy, for example, and such cars as S.P.A., Scat and Itala, some of which have never been seen in New York or Boston, the U. S. A. hotbeds for European cars some years ago, are seen in large quantities in Buenos Aires, Rio, Montevideo and Sao Paulo, and the natives speak of them with greater familiarity than of many of our popular cars selling under $1,500. There are such German makes as Adler and Horsch, never seen in the U. S. A., such French makes as Gregoire, Berliet, Peugeot, Alcyon and other names such as N.A.G., Lloyd, Pipe, F.N. and many others unknown in the automobile fraternity in the U. S. A. Not only has Buenos Aires these makes in quantity but she is literally filled with the more popular European makes such as Renault, Panhard, Clement-Bayard, Delaunay-Belleville, DeDietrich, Benz, Mercedes, DeDion, English Daimler, Rolls-Royce, Napier, Wolseley, Fiat, Isotta Fraschini, Metallurgique, Martini and every other European name known in the U. S. A.

Let it be repeated again that Buenos Aires and Rio have finer cars than New York City. Stand near Florida (Floor-e-da) the fashionable shopping street of Buenos Aires on which no vehicles are permitted between 4 and 7 and you see an array of limousines and landaulets, touring cars and open types grander than on Fifth Avenue. The cars are generally the last word in body design and fitting. Many dealers had all their bodies built by Van den Plas, Rothschild and the best European builders. The Argentine is fond of externals. Parade attracts him. He wants the best in automobiles; no matter what the chassis is, the body has to be the best. The limousines are large, hundreds are finished interiorally in the best cabinet woods with delicate inlaid work and they are as immaculate today as when first purchased. The automobile is a great criterion of social status not only in Buenos Aires but in many other South American cities. No car is too good for the wealthy Argentine. To-day his chauffeur and footman are better groomed than those seen on Fifth Avenue, New York, Commonwealth Avenue, Boston, or Michigan Avenue, Chicago. They, too, like the car, are immaculate.

Why European Cars?

The cities are literally filled with such cars. They are not the exception but the rule. In these cities the wealthy classes have, previous to the war, been spending their winters in Europe. Not one winter or an occasional winter but every winter. Paris, London, Rome and Berlin were their Meccas. They spent 3, 4 and 5 months there. They had no ties binding them with New York, Boston, Chicago or our other leading cities. Our language was different from theirs. We had nothing in common. It was but natural that European automobiles and European cars only should find a market, and it was further natural that Argentina and Brazil should buy the

best that Europe had. Argentines had the money and the time. The luxurious car naturally was ideal for a people that take a peculiar delight in appearances and that find an added delight in satisfying this desire in Europe, which still is to all South America finality in art, in dress, in style, in manners and fashions.

After this lengthy digression in attempting to paint the picture of the European car in South America and the South American desire for it, let us revert to the U. S. A. car that for years rapped more or less determinedly at the trade doors of South America, but which has only in the last year or so found a responsive and growing market. In analyzing why the U. S. A. car is advancing in leaps and bounds in the last 12 months, bear in mind first of all, that it has started into a different field in South America than where the European car was sold. The U. S. A. car got its start in the country and that is where it is to-day selling in rapidly growing quantities. The European car sold very largely in the cities. The Argentine rarely thought of using it in the country.

The word country is rarely if ever heard in South America or Argentina. It is the *camp*. Camp not only means the country in which all kinds of grains are cultivated and large areas where cattle, sheep and horses are fed in the open, but includes the cities, towns and villages as well. Practically everything outside of Buenos Aires is camp. When a traveler goes for a selling trip he is said to be out in the camp.

U. S. A. Cars for Country Work

The U. S. A. car started selling in the camp and that is where it is selling most to-day. Our cars were not fashionable enough for the city. There the taste was for Renault, Benz, Rolls-Royce, DeDion, Mercedes, Fiat, Panhard, English Daimler and Napier. The opinion of the U. S. A. car was that it was not grand enough for the city and that it would not run in the camp. There were no roads there, and if there were the U. S. A. car was not robust enough, according to Argentine standards.

To Ford must largely go the honor of exploding this Argentine theory. The Ford car has accomplished it in the last 2 years. It required about 1 year of terrifically intense education and demonstration, and only 10 months ago did Fords start selling in quantities in Argentina, Chile, Uruguay and parts of Brazil, Rio not included. Previous to August, 1915, Fords were selling at approximately 100 per month total in Argentina and Uruguay. Suddenly they jumped to 300 and 375 per month, and since then this average has been maintained, and everywhere you find the dealer 2 to 3 months behind in delivery. Ford must get the honor of conquering the camp.

Dealers Want U. S. A. Cars

Two years and even 15 months ago the low and medium-priced U. S. A. car did not appeal to the Buenos Aires dealer who counts all Argentina an area as large as U. S. A. east of the Mississippi, and with 8,000,000 population, as his territory. Our automobile factory representatives traveled South America but often could not get an audience. They peddled their cars from agency to agency, and more often left without a representative than with one.

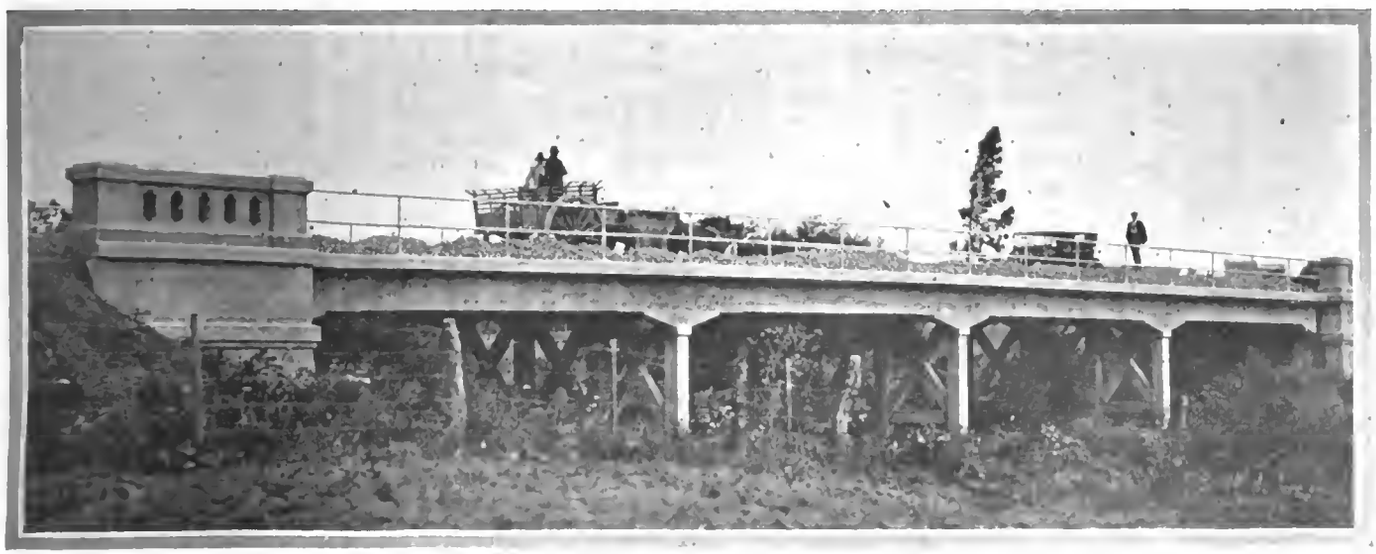
To-day it is all changed. Now the Buenos Aires, Montevideo and Sao Paulo dealers are after U. S. A. cars.

To-day our representative has the choice of five or six possible agencies. It is now a problem of selecting the most suitable, not a problem of discovery.

There never was a time when Argentine agents were more anxious for U. S. A. cars.

They are coming to the U. S. A. on nearly every steamer to look the field over carefully, visit the factories, inquire into the financial standing of the building companies and make a careful selection.

The Buenos Aires and Rio dealer does not like to make changes. He may be a little slow to tie up with a U. S. A. factory, but when he does, he hopes to make it permanent. He rarely changes. This is a characteristic of substantial South American business men.



Typical example of bridge construction on the government roads now being built across the country from Montevideo, the capitol on the south coast to the Brazilian boundry on the north

For the last 3 months there has been nothing short of a stampede in Buenos Aires for U. S. A. agencies. The same is true of Montevideo, Sao Paulo and such Argentine cities as Rosario, Cordoba, Bahia, Blanca and Mendoza, only to a much lesser degree. The same is also true in many smaller cities and larger towns scattered up and down the camp of Argentina. In every city visited during May and June, and there was nearly a score of them, the one inquiry was for U. S. A. agencies and information on U. S. A. factories and U. S. A. cars.

Many Agencies Placed

During those months agencies were placed for Maxwell in Buenos Aires and several other cities. The Dodge representative established his first agency in Buenos Aires, Montevideo and some other cities. The Chandler representative was making his preliminary plans. The Jeffery was placing agencies in Montevideo, Sao Paulo and other places.

Such makes as Ford, Cadillac, Overland, Studebaker, Hupmobile, Buick, Chalmers, Hudson, Oakland, and Scripps-Booth were already placed, some of them established years ago and others but a few months. Nearly all have taken on new life and are profiting by the stimulus given the U. S. A. car by intensive salesmanship. Ford and Studebaker are using the same well-organized sales systems as are being used in the U. S. A.

Naturally following in the wake of this newly found car business are some of our largest tire houses, several of which are taking prompt advantage of the inability of France, England, Germany and later Italy to supply tires. They are making unexpectedly rapid sales. In Buenos Aires the United States Tire Co. was just starting and its stock had not arrived. Goodyear has been under way for several months. Goodrich, the oldest, was established several years ago. Firestone and Fisk have been on the ground a short time but are doing well and several other smaller U. S. A. makes are being pushed.

Intensive Salesmanship Won

Dwell next for a moment on how this turn toward U. S. A. cars within the last 2 years was accomplished.

Virtually it was by the sweat of the brow. There was no royal road to success. It was not an order-taking program but an intensive salesmanship one.

Two handicaps had to be overcome:

1—There was the inherited dislike, if it may so be called, for U. S. A. cars.

2—There was a deeply founded belief that no car would prove satisfactory in the camp without improved roads and frequently without any kind of roads.

In making first sales in the camp the policy of one agent may be taken as a criterion. One of the most successful was a young Texan, O. P. Harris, who learned his lesson in salesmanship in U. S. A. He invaded the stronghold of the Argentine in the province of Pampa Central, one of more recent settlement and naturally a poorer field than the province of Buenos Aires, which is the oldest and best settled section of Argentina. He went to the camp with the Ford, the one he demonstrated with and sold. He called in the morning on the big land owner known as the Estanciero (E-stan-see-air-o). He did not get an audience. He was turned away. There was no use for U. S. A. cars. He was back before night, perhaps to be again turned down. He always came back. He got an audience. He got the Estanciero in his car. That was his aim.

Once seated in the car the sale was as good as made. Harris went everywhere on the huge farm or Estancia (Es-stan-see-ah). No trail was too rough. The demonstration lasted hours; sometimes 2, sometimes 3 and often 4 to 6. Harris took the wife of the estanciero and perhaps the children and another demonstration started. He had to prove his car and prove that the camp could be conquered as well by the car as it had been by the picturesque cowboy, gaucho (gow-cho) they call him in Argentina. It was now or never. Harris knew there was no second chance. He had to make good. He made good. His demonstration accomplished its object. He sold cars. He sold 125 in the one province in a few months.

So were the first seeds of the U. S. A. cars sown in the Argentine camp.

The Movement Grows Fast

Once started, the movement spread fast. One Estanciero told another. The car was a utility vehicle and not a part of social life as it had been in Buenos Aires.

One fact which greatly aided the introduction of the low and medium-priced U. S. A. cars in the Argentine camp was the high price of wheat and corn due to the war, and also to the great demand for Argentine beef, mutton and pork. The rising prices for these gave ready money to the Estanciero just as similar conditions caused unexpected streams of gold to flow into our own—Minnesota, Kansas, Dakotas and other wheat States. This ready surplus was freely invested in cheap cars, giving great impetus to a movement that otherwise might have struggled along much slower for several years. Success was crowded into a few months that might have needed years to achieve under ordinary circumstances.

Demand Is Spreading

It is argued to-day in Argentina that were it not for this situation the U. S. A. car might still be where it was before the war. Without disputing this part the fact remains that the U. S. A. car has sold, that it is selling and that there is a steadily growing demand among dealers for it.

This introduction of the U. S. A. car into the camp in Argentina, and we can similarly say into the camp of Uruguay and Chile and in such a rich State as Sao Paulo, in Brazil, is doubly interesting to U. S. A. makers when still further handicaps under which it was introduced are studied. There are several of these:

1. The price of gasoline in Argentine has constantly risen since the war. Previous to the war, England was the great supplier of gasoline, naphtha

as it is called in South America. To-day U. S. A. supplies practically all the gasoline. But the rise in price has been due to the same causes that have been active in North America, namely, scarcity of crude and tremendous demands for gasoline from Europe.

Fuel at 70 Cents a Gallon

But you must add to this the enormous increase in ocean freight between New York and Buenos Aires or Rio or Montevideo. Nearly all gasoline going to South America goes in sq. 5-gal. cans. Two 5-gal. cans are crated together and form a case. Before the war freight amounted to 20 cents a case, it rose as high as $1.70, an eight-fold increase, and the average rise was $1.20, or six times the normal rate. To-day gasoline sells as high as 70 cents in U. S. gold per gallon, in many places in the camp where U. S. A. cars are selling in quantities. In several cities the price is sufficiently high to compel quite a few owners of high-priced cars to store them in garages.

In spite of this handicap the U. S. A. car got its start and is selling in surprising quantities.

2. Perhaps a greater handicap of the selling of U. S. A. cars to-day is the question of freight. For some months freight has been $1 per cu. ft. between New York and Buenos Aires or Rio. It was as low as 20 to 35 cents. Last August the freight rise started and kept steadily on until May 1 when the apex was reached. To-day it is easier. Because of the freight rise, prices of U. S. A. cars in many cases were raised all through South America. On May 1 Ford prices went up from $1,750 up to $2,050, Argentine dollars or pesos (pay-sos). Many other increases were on a like scale, but this did not stop selling, although it did not come in the Argentine selling season.

3. A third handicap to the selling of U. S. A. cars is the unfavorable exchange rates between Buenos Aires and Rio and New York. Exchange is a problem little known of in much of our home automobile business, but is on the lips of everyone in South America. One automobile business man in Sao Paulo, Brazil, told me of losing $150 U. S. gold on one payment he made in New York on cars. The rate of exchange was unfavorable on that day. He had waited several days for it to improve, but it went from bad to worse.

Gasoline, Freight and Exchange

Gasoline, freight and exchange are the three great factors making it hard to sell U. S. A. cars in South America.

But if it has been a task to sell U. S. A. cars in Argentina, Uruguay and Brazil it has been impossible to sell, too, the expensive European cars. They stopped selling in 1911 when the financial crisis arrived. You see to-day salesrooms filled with the same cars they had in 1911. You ask a dealer how many cars he has sold since the war started and he answers not a single one. Some have not sold one for 3 years, and a few for 4 years, in other words, since the crisis of 1911 there are a score of dealers filled up with old European models.

You ask how can these dealers stand the financial strain of not selling a car for 4 years and having a showroom filled with them. The answer is brief: Those who were exclusively dealers and sold cars only did not stand it—they went broke. But there were few exclusive car dealers. The majority of dealers were large machinery houses with whom automobiles were a side line. They sold farm machinery, electric machines, hydraulic machinery and machinery of all kinds. Thus not having all their eggs in one basket, they withstood the crisis and are still able to carry the automobiles.

It was these large houses who 2, 3 and 4 years ago would not get interested in a U. S. A. car. They had a deaf ear for all U. S. A. car representatives who went to Buenos Aires and Rio, Montevideo and Sao Paulo for agents. They had had enough of selling automobiles. They had overbought and were caught. We could not interest them in U. S. A. cars.

Within the last 18 months these business houses have seen 2 or 3 makes of U. S. A. cars start selling in the camp. They see chances of coming back into the automobile industry. They see attractive chances of making more money out of U. S. A. cars than perhaps they ever made out of European cars.

Here is the keynote together with other numerous reasons that there is to-day a great and growing demand for U. S. A. cars and accessories in Argentine, Brazil, Uruguay, Chile and perhaps all west coast cities as well.

Why a Throttle Lever?

FIVE years ago there were many cars still being built without an accelerator pedal, and the latter, when put on, was an addition to the hand control and not a substitute. In Europe at the same period many cars had accelerator pedals only and no hand throttle whatever. Actually there is no need for both because the driver invariably uses the pedal when it is provided and the function of the hand throttle lever is simply to set the throttle in the proper place for idling or starting.

An accelerator pedal alone, without any hand control has the drawback that the proper throttle position for the slowest idling varies from day to day owing to the temperature and other variations. This means that some adjustment is needed which will alter the exact point to which the pedal returns when the foot is taken off it. Now, it is easy to provide a dashboard lever which will perform this feat without anything like the same number of parts required to connect a lever above the steering wheel with the carbureter.

Furthermore, controls passing down the inside of the steering post are always liable to rattle, and it would be easier as well as a little cheaper to make steering gears with only one internal control tube. The clearance could be doubled and the chances of rattle reduced in proportion. There is also no doubt that a single lever above the wheel looks much neater than the conventional double quadrant. There seems good reason to think that if some prominent manufacturer would make the move the industry would be quick to abandon the old-style throttle lever.

No doubt many of the old-time drivers who were used to the hand throttle before the days of the accelerator will disagree with this view, they still use the hand control or think that they do. Let it be remembered, however, that these men are but a very few among a vast multitude, and the newer motorist makes practically no use at all of the hand throttle lever.

Less Weight and More Power for New Franklin

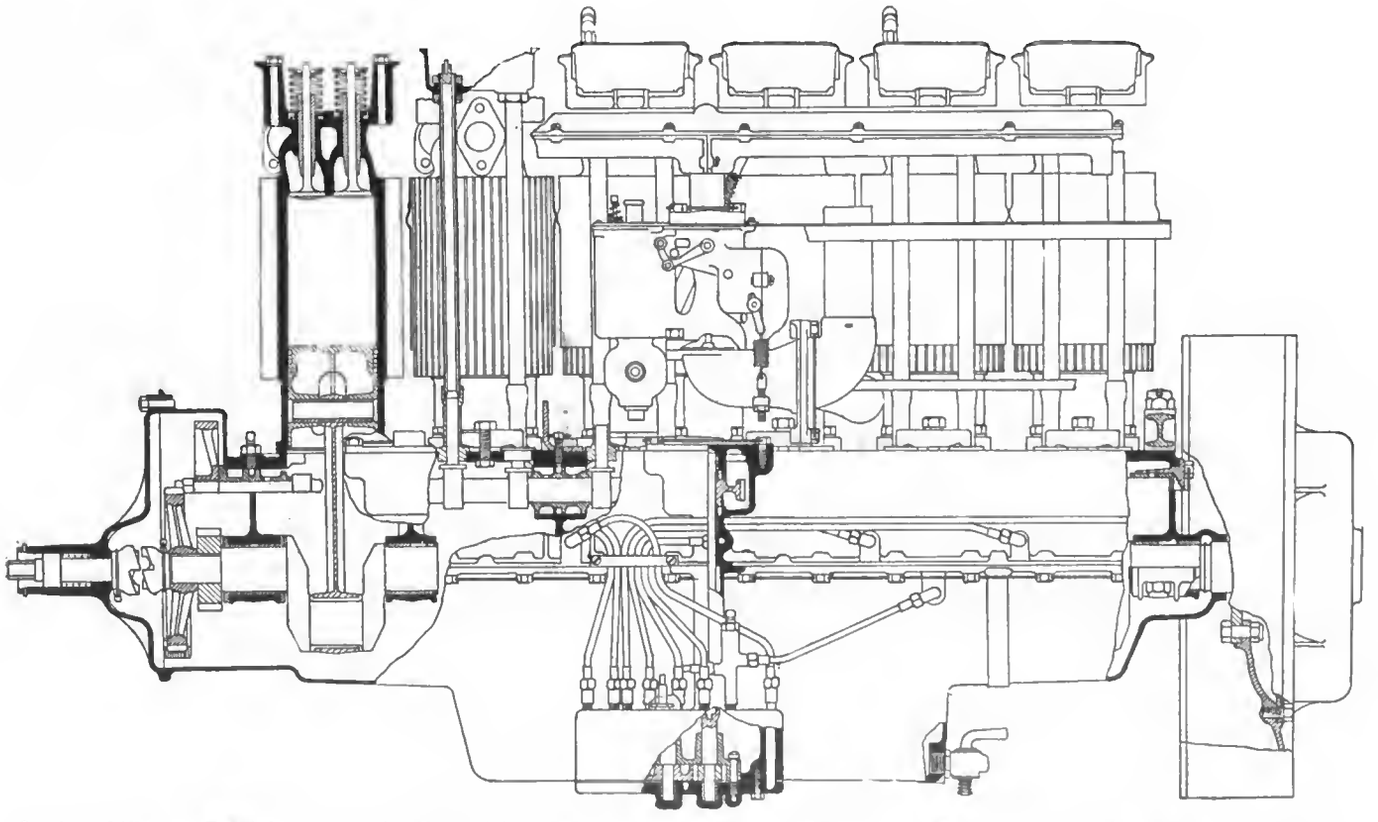
Has Smaller Engine of Higher Hp.—Weight Just Over 1 Ton—Appearance Improved—Price Reduced to $1,850

THAT the H. H. Franklin Mfg. Co., Syracuse, N. Y., had a new model in preparation was known to a few over a year ago, which means that the chassis now announced has had a very great amount of work put into it and has been tested with especial thoroughness. The results of this careful preparation are quite remarkable, for the new car is a very considerable advance on previous Franklins, good though the latter undoubtedly were.

400 Pounds Saved

The 1916 Franklin has been generally accepted as the lightest comfortable touring car of its capacity in the world, this low weight being obtained by scientific design, careful choice of material and elimination of every superfluous pound of metal. That as much as 400 lb. could be trimmed off it without depreciating performance or comfort was a surprise even to the Franklin engineers, but this has been done and both performance and comfort are improved thereby. This large amount of weight has been saved without making the car smaller. The new engine in lighter, being a trifle smaller in the bore, the gearset has had several pounds cut out and both axles are lighter. All the petty details have been examined with a microscope, so to speak, and ounces cut here and there; more forgings and fewer castings are used and aluminum takes a bigger part than ever.

The general lines of the chassis remain almost unchanged. The air-cooled engine, now 3¼ by 4 in., is externally similar to the old 3⅝ by 4 in.; the wood frame, full elliptic springs front and rear, and the amidships gearset are all retained, in fact, it needs a close examination of the chassis to find the changes. Externally the finished car has been improved in appearance very greatly. The sloping hood has had rounded corners substituted for the square ones, and it is wider, making a flush joint with the cowl all the way around. The bodies have also been rendered smoother and every one in the whole range of types is as good looking as another, the closed styles being, perhaps, especially distinctive. Also a new design of four-passenger roadster, which is not a clover leaf, is likely to prove popular, as it has all the close-coupled effect and is much easier to enter. There are divided front seats and a back seat in just the same relationship as in a clover leaf, but the doors are almost double as wide as usual. When open the door allows entrance to be made to either front or rear seat. Still easier entrance to the rear seat can be had if desired, by tipping the front seats, both of which are hinged so as to fold forward.



Section of the new Franklin air-cooled engine 3¼ in. by 4 in. This is on much the same lines as the former type but is a little smaller, though producing slightly more power. Atwater Kent ignition has been substituted for the magneto and the use of a Stewart vacuum feed allows the carbureter to be placed higher

The sedan and brougham bodies have been altered by the substitution of a V-fronted windshield for the flat pattern and the lines of sides, front and roof have been blended in a particularly happy way. It is not too much to say that the whole closed car range resembles the best class of custom bodywork. Great care is taken with the detail finish of all the bodies, and one noticeable point is the solid way the doors close; in fact, the bodies all give the impression of weight and massiveness; it needs an examination of the unfinished shell to realize how very opposed to the truth this impression is actually, for they are light as well as strong.

The principal car of the Franklin series is, of course, the five-passenger touring job, which sells for $1,850. The four-passenger roadster costs $1,850 also, and there is a two-passenger roadster at $1,000, this having a very big boot under the rear deck which would hold enough baggage for a 3 months' tour. The sedan costs $2,750 and the brougham, which is merely a smaller sedan, $2,700. In addition to these cars, there is a limousine for $3,000 and a very smart town car at the same price, while the eighth model is a cabriolet selling at $2,650.

Franklin expects to make 10,000 cars in the next 12 months, of which about 7000 will be the touring car and 1000 roadsters for two or four passengers. Of the sedan 1000 will be made and the other closed types will complete the schedule. It is thought probable, however, that the demand for the four-passenger roadster will exceed this estimate, judging by the orders now being placed by dealers.

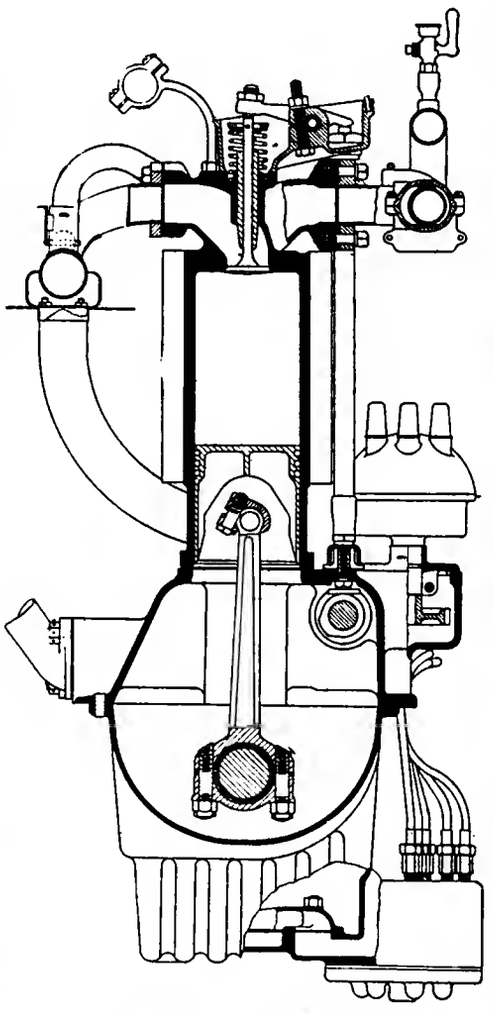
Engine Not High-Speed Type

Although it produces its maximum of 31 hp. at a higher speed than the maximum of the older motor the new engine is hardly a high speed design, the peak of the power curve coming at about 1700 r.p.m. The maximum torque is 112 lb. and occurs at a little over 1000 r.p.m. It is a small engine, the 3¼ by 4 in. dimensions for the six cylinders, making the total piston displacement 199 cu. in. and the formula horsepower is 25.3. On high the gearing is 3.9 to 1, the wheels being 32 in., which means 1950 revolutions of the engine per mile, or a total displacement of just under 390,000 cu. in. per mile. Since the weight is under 2300 lb., this gives a large ability, which is evidenced on the road by rapid acceleration on high. The maximum speed of the car is 50 m.p.h. or over. That is to say, 50 m.p.h. is reached easily and more under favorable conditions.

The engine is 150 lb. lighter than the old power plant, but, apart from the reduction in bore, it is little changed. The air-cooling system is exactly as before, save that the flywheel with its multiple blade lower construction is now an iron casting instead of being built up. Vertical steel fins are made integral with the individual cylinder castings by having the iron poured around the strips of steel and very light aluminum jackets guide the air draught downward from the heads of the cylinders.

The overhead valve mechanism has been lightened in detail, so that there is less inertia in the operating parts and the point of contact with the rocker on the valve is so shaped that the action of the rocker cannot put any side stress on the valve stem, so causing wear on the guide.

The most marked change in the engine is the substitution of Atwater Kent ignition for the magneto. The Franklin engineers consider that this battery system gives better results at low speeds and equal results at high rates of revolution, while it is again an opportunity for saving weight. For control of the ignition point the Atwater Kent automatic advance is used, there being no spark lever on the steering wheel. Lighting and starting are performed by a Dyneto single unit machine driven by silent chain and located at the front right end of the engine; it is very accessible and the wiring is also simplified to the last degree. All the important junctions, fuses, etc., are carried on a panel in the cowl board and the spare bulbs for the lamps are also held in sockets on the same panel, so that they are perfectly protected and always accessible in a hurry. The carbureter is the standard Franklin design, with which the various economy runs have been made. It has been raised considerably and now has a Stewart vacuum feed from a rear tank.



Cross section of the Franklin engine

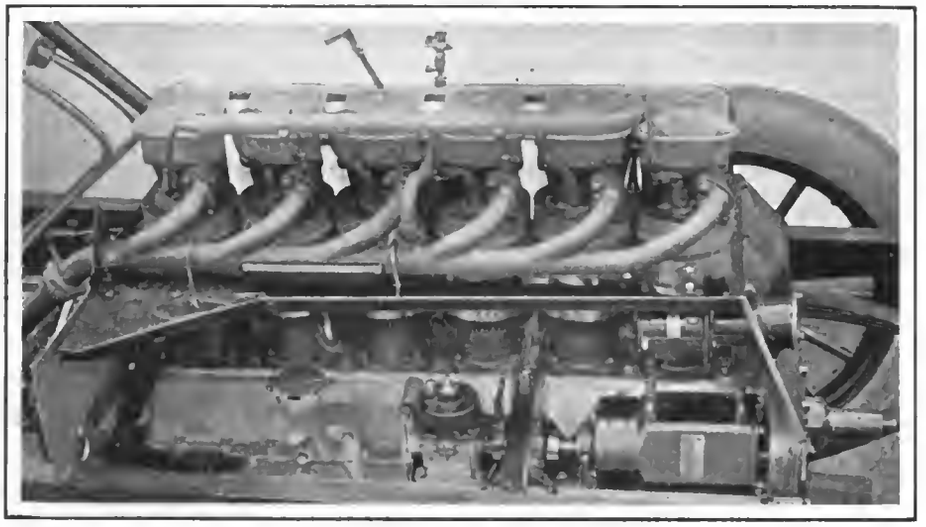
Incidentally, it is stated by the manufacturers that the new model with its reduced weight will be able easily to break all previous economy records, and that the average man using the car in the average way without taking any special care for economy ought to get well over 20 miles per gallon. This, of course, being a minimum and not a maximum. In other words, the economy is improved in the same proportion as the weight is decreased.

New Aluminum Piston Type

Seeing that the normal working temperature in the Franklin engine is distinctly high, the makers were not very ready to believe in the aluminum piston, but they have now adopted it as stock practice and consider that the better mean effective pressure of the new engine is largely due to the improved piston cooling obtained. At first there was a little trouble from wear on the skirt; it was difficult to get a close enough fit to insure absence of slap without abrasion. The trouble was overcome completely by turning a shallow, square groove of screw thread form from the bottom of the skirt to just beneath the lower ring. This holds oil securely and allows a smaller clearance than is possible with a plain piston.

There is an interesting lubrication system employed, individual oil supply being sent to every point. The oil pump, which is a conventional gear pattern, is mounted on a large plate, and the delivery from the pump is distributed to a number of oil leads by means of passages in the plate. Actually the plate is die-cast aluminum with distributing grooves, and these grooves are made into closed passages by putting a piece of thin sheet copper over the face. This gives direct pressure feed to all bearings on the crankshaft and to various other points.

Bearings, and details on the underpart of the engine are now more accessible because the boot or under cover has



Franklin engine, showing mounting of motor-generator, tire pump and horn

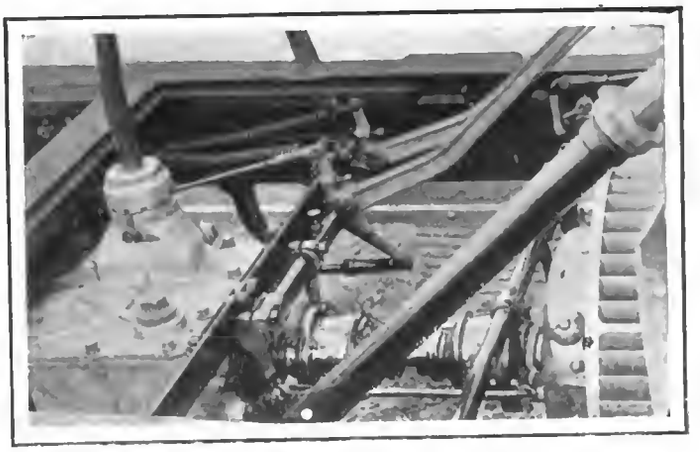
been abandoned, the sides of the crankcase being now joined to the frame sills by sheet aluminum guards, leaving the bottom of the crankcase exposed. The elimination of the under cover also aids in reducing the weight.

Gear-Shaft Location Changed

The previous Franklin gearset appeared remarkably light, but the new design is still lighter. Instead of being side by side the shafts are now one above the other and the square shaft has been replaced by a splined one. Three speeds are provided and it is noteworthy that the second gear is very quiet in operation, probably owing to the stiffness caused by the short shafts and very compact case. The gear shift lever is housed on the top of the case, working in an adjustable ball joint; it is a tube with solid ends brazed in, thus being very light though stiff. The emergency brake lever has been removed from its central position and is now on the frame at the driver's left, where it lies well forward and out of the way. It does not obstruct the entrance from the driver's side, and its absence from the middle position makes more foot room. There is no intermediate linkage for this brake, as the pull rod goes direct from the lever to the rear axle. The clutch is unchanged, and the foot brake is still on the back of the gearbox, operating with great power and smoothness.

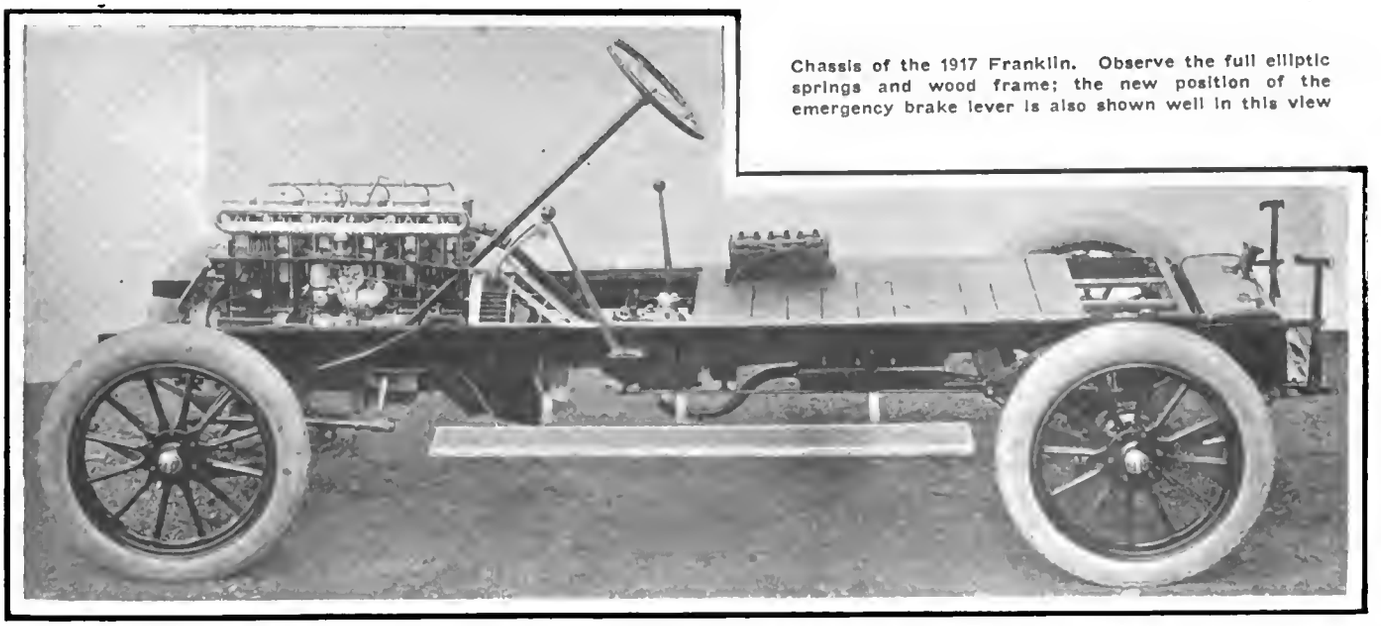
Despite the smaller weight and also despite the fact that the springs are shorter, the new car rides much better than the last series. A really rough railroad crossing can be taken at 20 m.p.h. without shaking a passenger off the seat. The explanation of this is in the axles, whence a large amount of weight has been taken. From the rear axle 25 per cent of its original weight has been removed, and from the front axle 30 per cent. This is due to the use of finer forgings and the elimination of some redundant parts.

Another effect of the small weight is to make the car so easy to steer that the first impression on taking the wheel is that something has come undone. The effort required to move the wheel is so slight that a child could steer the car easily, and a woman could drive all day without tiring her arms. There are no cars made anywhere in the world that steer more easily and extremely few that are as light to handle. The facility of control extends to the clutch, brakes and gearshift, all of which move without effort.

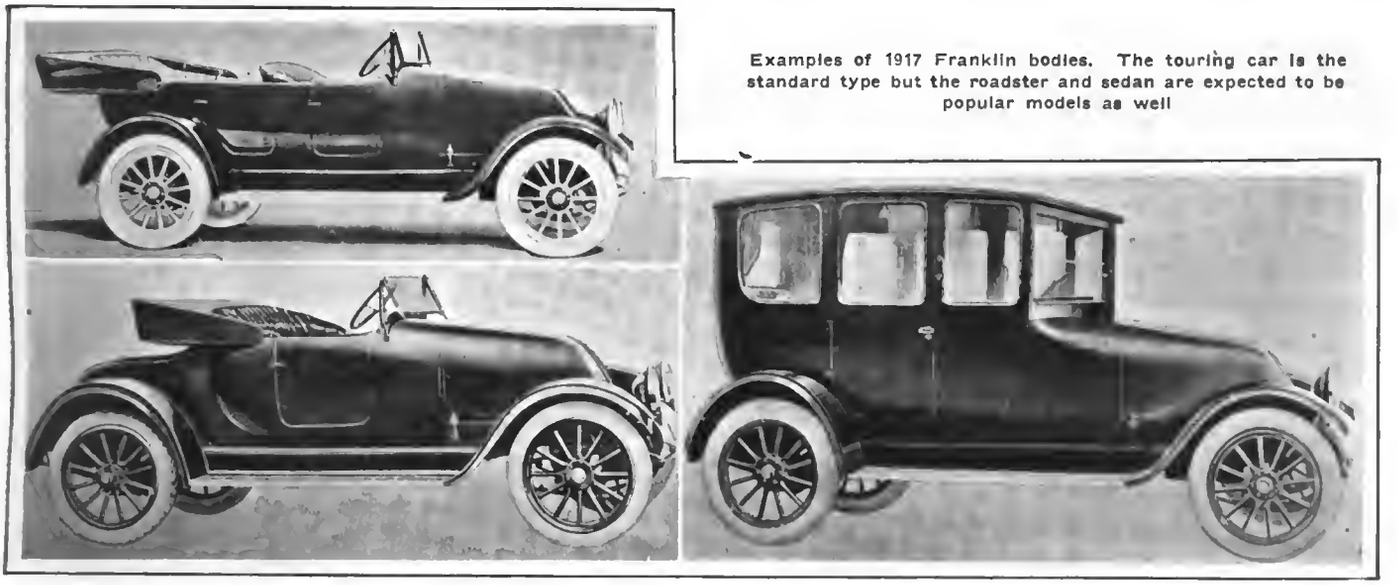


Centrally placed gearbox on Franklin showing the pedal assembly

There is no need to itemize the fittings. All the customary



Chassis of the 1917 Franklin. Observe the full elliptic springs and wood frame; the new position of the emergency brake lever is also shown well in this view



Examples of 1917 Franklin bodies. The touring car is the standard type but the roadster and sedan are expected to be popular models as well

equipment is given, and all of it is of good quality in keeping with the character of the car.

In regard to equipment, the cowlboard has been well arranged, the clock and speedometer both being under the driver's eye, while the carbureter control and the switches are ready to his right hand. The horn button is mounted on the side of the door, where it can be operated either by the hand, or by side pressure of the knee, and a complete tool kit is contained within the upholstery of the door, each tool being in a special clip. The compartment has a lock.

A single tire carrier is built in conjunction with the gasoline tank brackets, and provision has been made for attaching luggage at the front of the left running board. Strap loops are mounted to retain the straps which secure trunks or other luggage, and on the inner edge of the running board stops are properly placed to hold the trunk in position. The luggage space accommodates a two-suit-case trunk, 10 in. high and 15 in. wide, and 30 in. long. Tires on the open cars are 32 by 4 in. and 32 by 4½ for the closed models, to allow for the different body weights.

Shortcomings of the Conventional Lifting Jack

WHEN it is necessary to raise a wheel off the ground to change a tire the inadequacy of the conventional form of tool used for the purpose becomes apparent. Lifting jacks as a rule are ingenious and so far as the actual lifting gear is concerned there is no criticism to offer. It is, though, rather remarkable that no automobile manufacturer has yet seen fit to provide any definite place on the axle where the head of the jack will take a firm, square seat.

No Firm Contact Point

On the rear axle it is sometimes positively difficult to find a place near the end where the head of the jack will go at all, because of the various protuberances on the brake bracket and because of the tie rod stay. Thus the car is often none too secure and stable when resting on the jack.

When it is a front wheel in question there is certainly a place to put the jack, but one generally finds that the jack has to be set much lower to go under the front axle than it needs to be at the rear, which means that the jack cannot be kept in the kit so set that it is ready to lift either front or rear axle with the minimum of strokes and in the minimum of time.

A Special Bracket Possible

It would cost nothing and would be quite easy to have some special place on one of the brackets at each end of the rear axle designed to give a firm contact for the jack. All that is needed is a downwardly projecting lump of metal which would clear the tie rod and all other projecting parts. The sketch, Fig. 1, shows this idea. It would be easy also to have the distance from the jack abutment on the rear axle to the ground the same as from the underside of the front axle to the ground, so that the same setting of the jack would suffice for either axle.

Carrying the idea a stage further, instead of a flat abutment on the axle there might be a lug with a hole through it, as sketched in Fig. 2. The jack would then need a special form of head which would hook into the hole in the lug. This would mean a special jack for all axles of the same make, but it would provide perfect security. A car could not fall off such a jack as long as the base of the jack rested upon firm ground. The second suggestion was made by a correspondent in *The Autocar* (England) as long ago as 1913, but the idea never found any supporter among British manufacturers. It seems difficult to understand why something of the sort could not be done as the convenience would be very real. Every car has to have its tires changed many times during its life, so why not make the job as easy as possible?

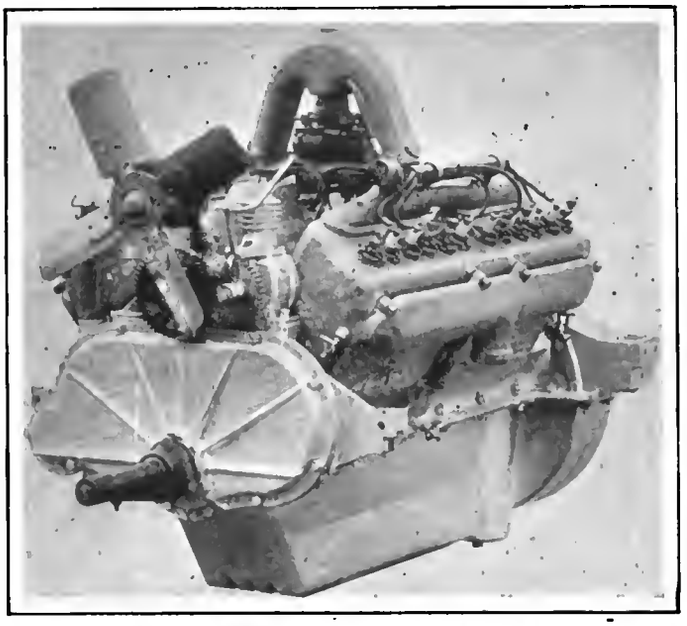
Five Bodies for National Twelve

Detail Refinements Make Car More Accessible—High, Narrow Radiator Adopted—New Four-Passenger Clover-Leaf—Seating Layout Rearranged, Giving More Comfort for Passengers



National twelve engine, showing outside arrangement of the valves. High-tension magneto ignition is a feature

A NEW series of National Highway twelve-cylinder car is just going through production in the Indianapolis factory and incorporates several changes over the model marketed last season. This is a companion car to the National Highway six which is being continued. Following the general trend, prices are higher this year on the twelve-cylinder model than last, the increase being $130 per car, making the price now $2,150. This includes extra seats, however, while last year these seats were sold at $30 extra.

A number of detail improvements have been made throughout the entire car. In the first place the touring body has been increased in size and now instead of being a six-passenger job, it has a full seven-passenger capacity. Although the improvements are numerous, for 1917 the same general chassis layout on the 128-in. wheelbase will be adhered to. Instead of an option of 34 by 4½ or 36 by 4½ tire, the regular equipment will be 34 by 4½ which was the choice of the majority of buyers during the last season.

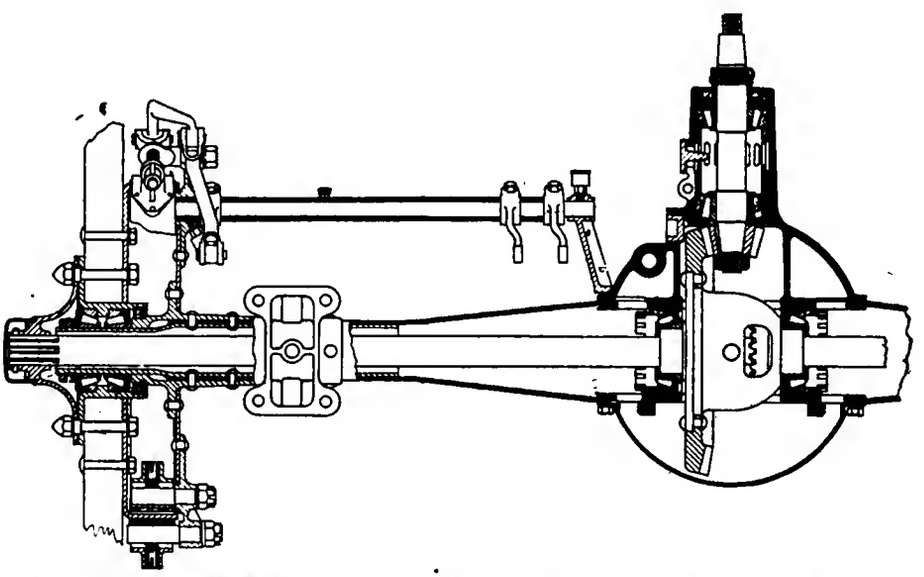
Many Detail Improvements

Probably the most notable change on the new National Highway twelve-cylinder car is in the seven-passenger touring body design. Although the chassis is the same length, the new body is 3 in. longer. It has a center cowl and there is an aisle between the two front seats. In the tonneau under the center cowl are two locked package compartments. The front seats are larger in every dimension and there is also more room in the driver's compartment. The body is wider than in the former series and there is more carrying capacity under each of the three seats. In addition there is a tool compartment in the left front door as on the former models.

Five Body Styles on Twelve

The new Highway twelve cars are furnished in five different body styles. In addition to the seven-passenger touring car there are a four-passenger touring car, four-passenger roadster, five-passenger all-weather sedan of the Springfield type and a three-passenger coupé. In the open models there is a new design of side curtains and these are fitted to the doors and so arranged as to permit the curtains to open with the doors, thus giving a closed car effect which is very useful in rainy weather.

The arrangement of the extra seats has been carefully worked out so that the tonneau floor is smooth and the folding seats and their supports are fitted flush with the floor when the seats are folded. A new and specially designed tire holder in the rear has the advantageous feature of requiring but one strap and provision is also made that the spare tires can be locked if so desired. Another feature of convenience is that the gasoline tank filler has been moved over to the right side near the right fender. It is now provided with a hinged cover which is held in place with a wing nut. This gasoline tank cover cap is easier to open than the old one and by being hinged it is impossible to loose it. A change which alters the appearance of the car somewhat from the older model National is that the radiator has been altered so that it is now 2 in. narrower and 2 in. higher than before. This gives a proportionately higher hood and has necessitated somewhat the change of the customary National



National floating rear axle in section. Taper roller bearings are used. The axle is light but strong

radiator emblem, as far as size goes. The shield design, however, is still maintained in spite of the change in size.

A study of the exterior of the car will reveal some other minor differences which may be particularly noticed in the fenders which are an inch wider and of new design in the rear and also the slanting windshield, the straight side of body instead of the tumble-home type formerly used, the flush doors and the necessary alteration in general lines to coincide with these changes. In equipment also a few alterations have been made, particularly on the dash, where a new oil pressure gage with a unique dial design has been installed and also a new combination ignition and light switch which is locked by a special key. The keys for these locks are not interchangeable.

Four-Passenger Clover-leaf

The clover-leaf design which was marketed last year as a three-passenger body has now been made into a full four-passenger job. This has been accomplished by increasing the body all around and by moving the rear seat back 4 in. The back of the rear seat is higher, making it fully as comfortable as the front seats.

Outside Valves for Accessibility

The National Highway twelve motor is a product of the National company's own shop. It has a piston displacement of 338.5 cu. in. and a bore and stroke of 2.75 by 4.75 in. It is a high-speed type throughout and is particularly distinguished by the use of outside valves which make it very accessible. The electrical apparatus and other motor accessories are located between the arms of the V where they can be easily reached.

Two separate blocks of six cylinders each are used, both L-head type and with two independent camshafts. No effort has been necessary to install synchronizing means for the two valve actions as they are altogether independent. The timing gearset is quite similar to that used on the ordinary T-head motor, and the drive for the auxiliary apparatus in the center of the V is taken off the right camshaft by a silent chain.

Pressure Oiling System

In working out the lubricating system the feed is practically all under pressure and is regulated by the output of the gear pump which is located in the oil base having a large screen on the suction side and also a gauze strainer in the form of a tray covering the whole top of the oil pan, but there are no dip troughs as the crankshaft is fully drilled and

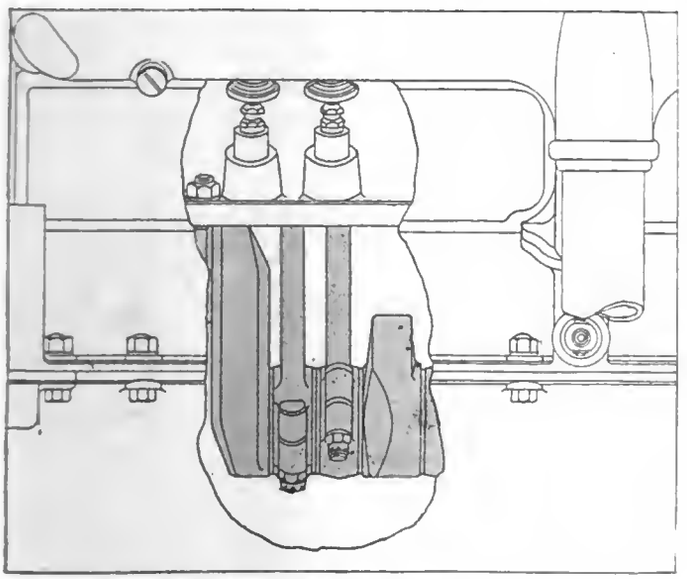
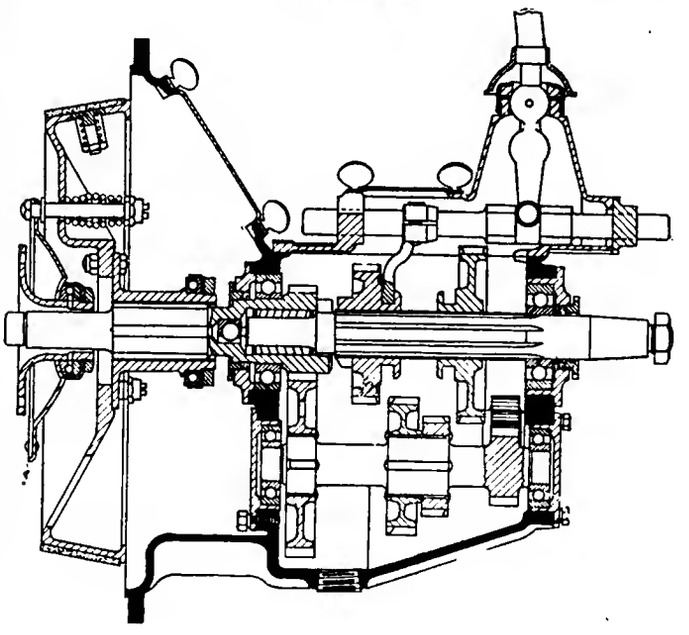
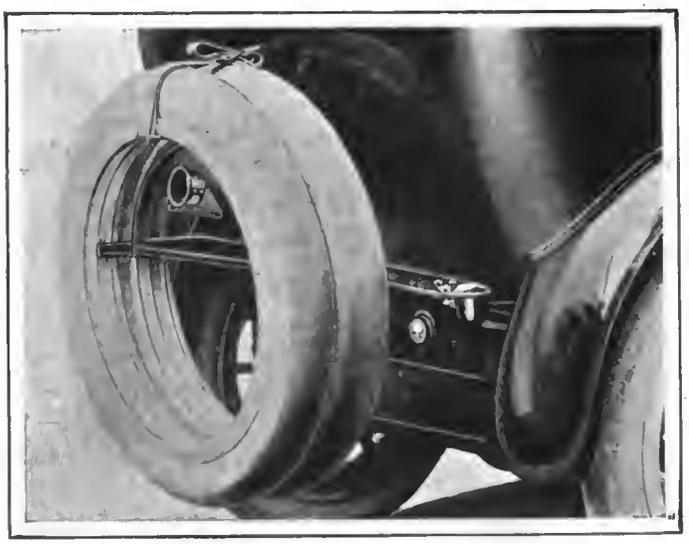
All tools for the National twelve-cylinder cars are conveniently carried in the locked compartment of the front door on the driver's side



National twelve side-by-side connecting-rod mounting and section through the three-speed gearbox used on this car





New tire carrier on National twelve, which requires but one strap as the holder fits firmly inside the demountable rim. Note gasoline tank filler and gage

the oil from the main bearings finds its way to the connecting-rod lower ends.

Oiling the Wristpins

Separate pipes lead to the timing gears and to each of the camshaft bearings while the piston pins are oiled by an inversion of the usual method of fully forced lubrication systems. As a rule the connecting-rod serves to carry the oil to the wristpins and then to the cylinders, but here the oil feeds to each cylinder at a point about 1⅛ in. from the bottom and reaches the wristpins through tiny holes drilled in the aluminum pistons. The latter have a V groove cut near the bottom, which is used to lift oil into the cylinder, as the absence of splash troughs in the body of the crankcase cuts down the amount of spray present. As to the oil pressure, this is not very high, the relief valve blowing off at 25 lb. per square inch. When the engine is idling the pressure is about 10 lb., and it rises gradually with the engine speed.

There is only one water pump, but this is duplex internally, the rotating member carrying two sets of vanes. One set feeds directly upward into the block of cylinders on the right and the other half of the pump delivers through a passage cast in the aluminum of the crankcase to the left block. This cuts down the piping materially and makes for efficiency and simplicity.

A few other facts about the engine that are interesting may be given, as, for instance, the weight of the piston, which is 8 oz. without rings. The valves are 1 5/16 in. diameter and the left is ⅜, giving a quite large opening, while the mushroom tappet provides a quick lift and descent, giving a slightly better valve diagram than the roller type. It is probable that the fan has some effect as a damper to the crankshaft, though it is doubtful whether any such aid to elimination of vibration is needed, but the short belt drive, when kept tight, provides a flywheel just as the Lanchester device, with a slipping possibility. Of course reaction from the fan would be cushioned a good deal by the belt and then the chain, but it is an undoubted fact that the presence of a fairly high speed fan does often have a steadying effect on an engine.

Flat Cantilever Rear Suspension

The clutch is an aluminum cone with leather face and the unit gearset provides three forward speeds, all shafts therein running on annular ball bearings. The propeller shaft is tubular and bears two universals, and the rear axle is floating. A flat cantilever rear suspension is employed and it may be noticed that the center bracket has the swivel pin located beneath the spring instead of above it, as is more usual. The springs are 51 in. long and 2½ in. wide with eight leaves each and their action is extremely satisfactory. The front springs have no noteworthy peculiarity, being 38 in. long by 2 in. wide, but special precautions have been taken in laying out the steering and the use of large ball thrust bearings for the front axle swivels makes the steering control very powerful.

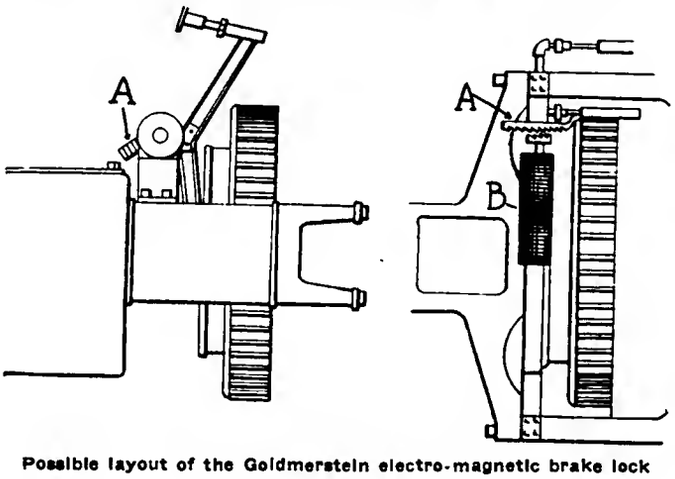
Superfluous Weight Eliminated

Throughout the rear axle taper roller bearings are used, and the type is floating, very strong steels being used so as to cut the weight as much as possible. This statement applies to the whole chassis which has few redundant parts and very little dead weight in any portion. Drive is by spiral bevel and the direct gear ratio is 4.4 to 1.

An Electro-Magnetic Lock for Brakes

LEON GOLDMERSTEIN, who will be remembered as having recently read a paper on aeroplanes before the Metropolitan Section of the S. A. E., has entered the accessory field with a novel form of automobile lock which prevents motion of the car by holding the brakes in position. The inventor points out that this will not only prevent the car from being stolen, but will prevent it from rolling down hill after the brakes have been applied and locked.

The device is electro-magnetic in operation, consisting essentially of a commutator switch and a solenoid which carries a bolt and locking device at the end. Application of the switch causes the coil to become energized, moving the core backward and carrying with it the bolt. By means of a slot arrangement in the cap of the solenoid which acts in relation to a groove in the core the device has been made jolt-proof. Another provision which has been made is that the brake can be locked regardless of the amount of wear on the brake band. The solenoid is made armor clad to increase its magnetic efficiency and mechanical strength and it is carried on a bracket. It can be made to engage with either the service brake or the emergency brake although it is recommended that it be fitted to the service brake, except in instances where the clutch and service brake are combined. A possible layout is illustrated, the pedal having a ratchet A attached to the lever. The solenoid is shown at B and when energized the ratchet seen on the end of the solenoid core is brought into engagement with the ratchet A, thus holding the brake so that the pedal cannot return.



Possible layout of the Goldmerstein electro-magnetic brake lock

The History of the Pneumatic Tire—12

Pneumatics Which, When Deflated, Served as Solids Tried Out and Found Impracticable—Inclosed Types—Origin of the Tire-Filling Business—Palmer's Early Work

The History of the American Automobile Industry—39

By David Beecroft

ATTEMPTS to devise a practical pneumatic tire, which, when deflated, served as a solid met with two difficulties. Sometimes the excess material caused by the deflation slipped on the base and sometimes it folded in ridges, but both were equally destructive. A short run would damage the tire beyond repair. The attractiveness of the idea seemed to warrant a large market if the device could be made successful, and it is certain that this can be done if the supporting surfaces which carry the load when deflated, are quite large and are lubricated, so that slipping between the tread and the base portions can take place without wearing them or without straining the sides of the tire casing. Some recent patents to Duryea show such a construction, although not yet on the market.

Other Less Practical Forms

Other still less practical forms of tires aimed to avoid punctures were brought out in 1892. A Chicago man advanced an idea, since frequently proposed, of inclosing the air tube inside the steel rim and providing a tire of solid rubber between the edges of the rim resting on the air tube, which rubber could yield and compress the air tube but would be so thick as to be unpuncturable. The little matter of friction, which would quickly ruin the solid rubber, was overlooked.

The Tire-Filling Business

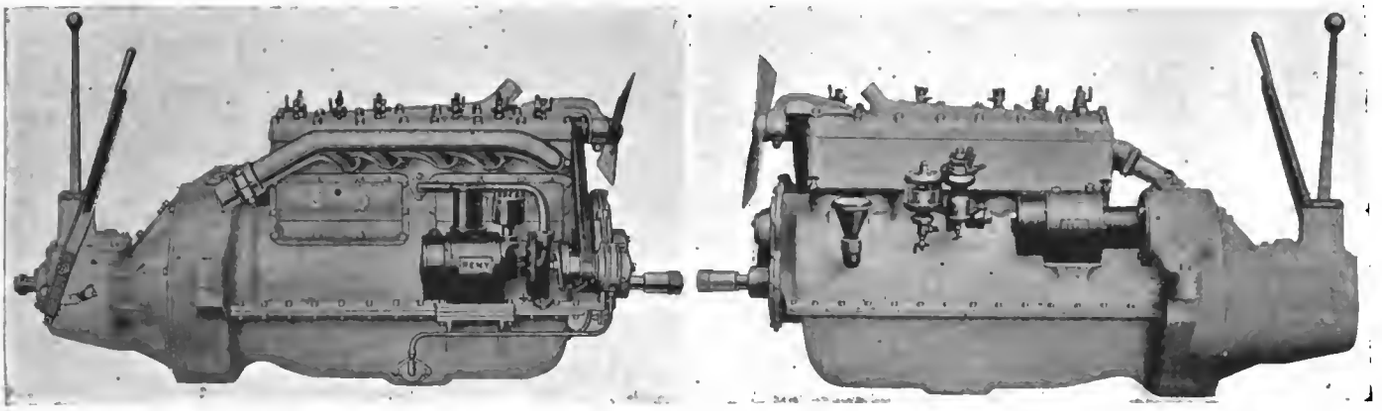
Another idea which has frequently come up since was patented by Sweeting in 1892, who proposed to fill the tire with water or with sponge afterwards soaked with water and thereby considerably expanded. It is a fact that a liquid will not flow through a puncture which permits air to escape readily and the thicker the liquid the larger this puncture may be, and yet the tire remain usable. This idea finally grew into a considerable business, the tires being filled with a sort of rubber imitation made under various formulas; some of these used the glue and molasses or glue and glycerine combinations of the printer's rollers while others used rubber compounds. In all cases, they were heavier and less resilient and therefore less valuable than the air tire and so have not found great favor. The water tire particularly failed because of its considerable weight and because it rendered the bicycle slow. Owen, some years later, suggested air chambers inside the rim which would serve as cushions and thus give a sort of elasticity to the incompressible water and perhaps overcome some of its disadvantages, but this device was never marketed.

Spring Tires in 1892

The spring tire again occurs in 1892, being shown by Whiting on a bicycle with two rims, one inside the other, and connected by radial, helical springs. The outer rim carried a solid rubber tire. Any arrangement of this kind requires that the bottom springs be strong enough to carry the whole load, and since the wheel turns, the total weight and strength of springs required is all out of proportion to the results. In spite of this, however, many attempts were made to develop a practical construction of this sort.

Palmer's Self-Healing Tire

Beginning about 1891, John F. Palmer began a development which grew into considerable importance in the next few years, although in a widely different line from that in which it began. As first shown, he had a valveless, pneumatic tire which could be inflated by inserting a hollow needle anywhere in the tread portion and which would seal the puncture just as the lump of unvulcanized gum inside the toy ball serves as a valve. Palmer's self-healing tire was more widely accepted than any of the other forms except the healing liquid and was made by vulcanizing a tube of fabric and rubber with the rubber on the outside followed by turning it inside out and splicing the ends. This put the rubber under a considerable compression and a puncture would be closed by the natural action of the rubber. Further, rubber looses its elasticity to a considerable extent if permanently held and so this original tendency to close an opening gradually disappeared and the tube ceased to be self-healing. Palmer's activities went into the thread tire, which was found to be considerably faster than the more common canvas ones and from which the modern cord tire has been developed.



Both sides of the unit power plant used in the 1917 Madison cars. The engine has a bore of 3⅛ and a stroke of 5 in. The cylinder head is detachable and the valves are inclosed and have easily removable brackets

Two Madison Chassis—Two Body Models

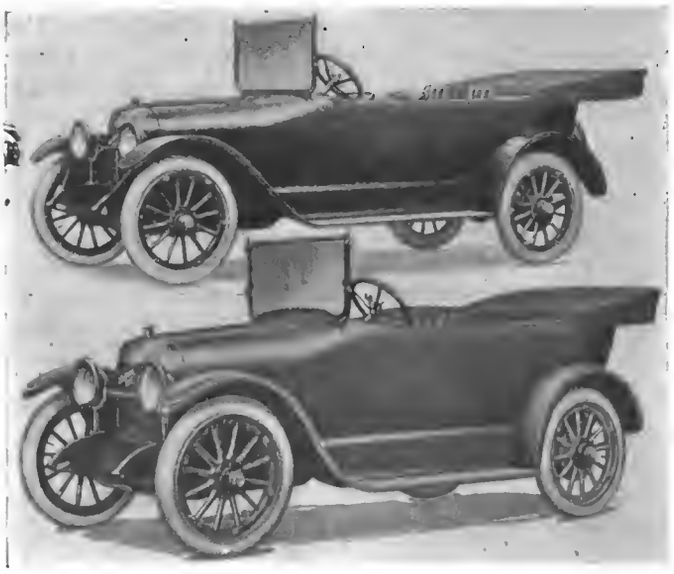
3 1-8 by 5-In. Unit Power Plant Used for Both Five and Seven-Passenger Cars—Refinements and Better Body Lines Are Only Changes for 1917—Valves Accessible

FOR 1917, Madison cars will be constructed upon the 6-40 chassis model and will be made in two body forms for five and seven passengers. Alterations in the body lines form the principal changes and these have been made to correspond to the flat cowl line which is in vogue this season. The prices for the five- and seven-passenger cars are $1,050 and $1,150 respectively.

Models Mechanically Similar

Rutenber engines are used in the Madison cars and the power plant for both the five- and seven-passenger model is identical. In fact the two cars are similar throughout except for a difference in wheelbase necessary to take care of the variation in body dimensions. The five-passenger car has a wheelbase of 115 in., while the seven-passenger has 124 in. A two-passenger roadster can also be secured if desired.

A unit power plant is used, the engine being direct-connected to a Muncie Gear Works gearset and clutch. Naturally in using the Rutenber power plant the improvements made in this during the past year have been incorporated in the Madison engines. The bore is 3⅛ in. and the stroke 5 in., and the six L-head cylinders are cast in a single block integral with the upper half of the crankcase. The valves are inclosed and the cylinder head is detachable.



The two 1917 Madison models, the seven-passenger being illustrated above and the five-passenger below. Note the new body lines with flat cowl effect

Three-Point Suspension

Three-point suspension is used and the rear support is secured by two legs on the rear of the crankcase casting. The third support is at the forward end of the engine and this is flexible, allowing the engine parts to be independent of any weaving of the frame. The pistons are cast iron and are fitted with three rings, two of which are close to the top and the third located just beneath the wristpin boss. The connecting-rods are of I-beam section, being drop-forged. The crankshafts are from 0.40 carbon steel and are balanced on the Norton machine before assembly.

Drop-forged camshafts, are used, the carbon content in this case being 0.20 and the diameter 1⅛ in. The cams are integral with the shaft and are hardened and ground, being carried in plain bearings at the center and front and at the rear in a double row S. K. F. self-aligning ball bearing. The valves are actuated by mushroom type flat followers which are offset 1/16 in. to distribute wear.

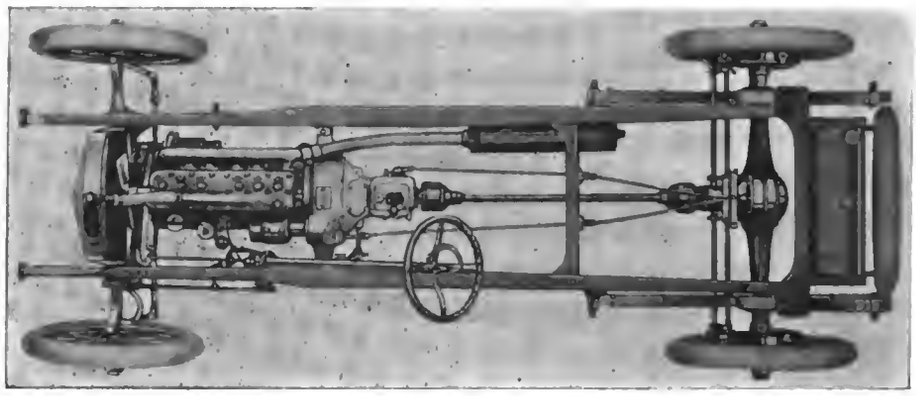
Valve Brackets Easily Removable

Two steels are used in the manufacture of the valves, carbon steel being employed for the heads while alloy steel is used for the stems. The diameter of the valve is 1 5/16 in. in the clear with a 5/16 in. width. A feature of the valve construction is that the entire valve bracket together with the lifting mechanism can be removed from the engine without disturbing the camshaft. This is done by removing the cover plate and stud nuts and then turning the crankshaft by means of the starting crank until the valves are at their lowest level. In arranging the valve timing the intake opens at 15 deg. after top center and closes 50 deg. after bottom center. The exhaust valve opens at 45 deg. before bottom center and closes 10 deg. after top center. Compression is 75 lb. absolute.

Power is transmitted by means of the Muncie Gear Works

dry-plate multiple-disk clutch, which is fitted with alternate disks of asbestos and saw steel. Annular bearings are used in the clutch release and these are lubricated by oil which is allowed to enter from the crankcase since the clutch housing is in direct communication with this part of the motor. The gearbox is a conventional three-speed unit of the selective type.

Two universals are used in the drive, the power being taken through the propeller shaft to a floating rear axle fitted with a pressed steel housing and Brown-Lipe nickel steel spirally cut gears. The axle shafts are supported on large annular bearings of heavy duty design and alloy steels are used throughout in the parts carrying the driving and torsion stresses. Hotchkiss drive is used, both torque and propulsion being taken through the rear springs.



Chassis of the 1917 Madison, showing three-point suspension of the unit power plant. Hotchkiss drive is used. The only material difference in the two chassis is in the dimensions affected by the difference in wheelbase

Remy Electric System

Electrically the Madison cars are Remy throughout. Starting is by an independent series-wound Remy motor used in connection with the Bendix drive for meshing the starting pinion with the flywheel ring gear. For lighting and current supply there is a Remy generator mounted on the right side of the engine and driven directly off the priming set. This generator unit also carries the Remy ignition distributer which is driven through a worm gear from the generator shaft. The generator also carries the regulator and automatic cut-out operating in connection with the Willard storage battery.

The gasoline system is composed of a 16-gal. tank supplied with a gage mounted on the rear of the chassis, a Stewart-Warner vacuum system, and a model M Rayfield carbureter provided with automatic air intake and climatic dash adjustment. Steering is by the T. W. Warner irreversible worm and full gear used with a steering wheel having an 18-in. corrugated rim. The wheels are artillery type 34 by 4 in. provided with demountable rims and an extra rim is located on the rear for carrying a spare tire. The tire equipment is Goodyear 34 by 4 in. all around, with the All-weather non-skid tread on the rear. Three-quarter elliptic underslung rear springs are used and the front are semi-elliptic. The steel used in the manufacture of these springs is English manganese with a double heat treatment.

Upholstery is in long grain black enamel leather with deep Turkish type cushions. On the five-passenger body a single front seat and rear seat are used, while on the seven-passenger the boat-shaped design is carried out with divided front seats and auxiliary seats which fold against the backs of the front seats entirely out of the way when not in use. The Madison standard body color is Richelieu blue.

Both bodies will be seen to follow the lines that are customary for the 1917 season, particularly as regards the flat section at the point of juncture between bonnet and cowl. The body curve sweeps back into the rear of the tonneau without a break and on the whole the design is one of smooth continuity. Particular attention is also being paid to seating arrangement and comfort this season, the camber of the seats and the curve of the seat backs being carefully worked out to fit the average passenger.

Equipment Is Complete

Full equipment is provided and included at the list price. Among the accessories provided with the car are a one-man top made of Neverleak, electric horn, Stewart-Warner speedometer, ventilating and rain-vision windshield, tire carrier, foot and robe rails, trouble lamp and a full tool outfit.

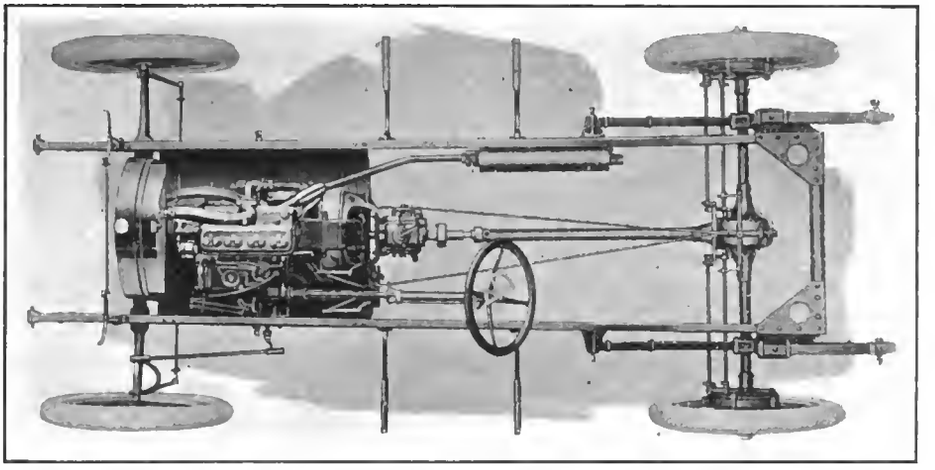
New Engine in Monroe Roadster

3 by 4 1-4 Block Power Plant of Brush Design with Overhead Valves—Disk Clutch Replaces Cone—Added Equipment —Price Higher



Chassis of the Monroe roadster for 1917, showing layout of the new power plant. This has overhead valves with outside adjustments. Note driveshaft torque tube

THE Monroe Motor Co., formerly located at Flint, Mich., but now at Pontiac, Mich., is now ready with its 1917 four-cylinder roadster, the only type of machine which it is making at present. Looking somewhat the same as the previous model, the new car, which is designated as model M-3, has a number of improvements over the model it replaces, all of which tend to make it a much better car. The price has been raised from $495 to $565, partly due to the added cost of materials, and partly to the added equipment and improvements in design and construction.

Chief among the changes over the preceding Monroe is the adoption of an entirely new engine to replace the 3⅛ by 3¾ in. type used last year. The new power plant is designed by the Brush Engineering Assn., Detroit, and has the same overhead-valve construction with outside adjustments that characterizes most of the engines Brush now lays out. This new block engine has a bore of 3 in. by a stroke of 4¼ in. and has the gearset in unit.

Along with the engine change, a multiple-disk clutch takes the place of the cone previously used and in the chassis there are several other modifications. The frame has been lengthened 3 in. at the rear to accommodate the longer rear deck now fitted, and the ratchet foot pedal that controlled the emergency brake heretofore has given way to the standard method of emergency control by a hand lever. In front of the radiator a sheet metal piece has been fitted between the frame rails. This helps to send the air to the radiator, and also acts as a mudguard for the radiator.

Crowned fenders have replaced the flat variety of last year, and they do much to enhance the outward appearance. This, together with the lengthening of the body back of the seat, suggests a larger vehicle, even though the wheelbase remains unchanged at 96 in.

Several additions have been made to the equipment. Demountable rims have replaced the clincher type, and in the rear the tires are non-skid treads instead of smooth. A muffler cut-out has been put on; a sight oil-feed has been put on the dash; a lock switch for protection against theft of the car has been added, and there is also a Stewart-Warner speedometer, no speed-indicating instrument being furnished as standard equipment previously.

Looking more closely at the details of the engine the cylinders and upper half of the crankcase are cast in one piece, a construction very often employed where the cylinder-head is removable, as in this case. The rocker arms and valves are carried in the head unit, being inclosed within a single cover plate that bolts to the top of the cylinder head. Protruding through the top of this cover plate are the adjusting nuts which, after the lock nut has been loosened, can be turned by hand until the proper clearance between the end of the valve stem and the rocker is obtained. The valve push rods run up to the rockers on the left side of the engine and the spark plugs enter the cylinders between the two rods of each cylinder as necessitated by the overhead valve construction.

Giving an idea of the 1917 Monroe roadster both coming and going. The splash guard shown in the front view helps direct air through the radiator

Units Compactly Mounted

Manifolds are on the right side, the intake having but a single connection to the carbureter pipe at the center of the head casting. Hung from a bracket, attached to the right rear side of the upper crankcase, is the Auto-

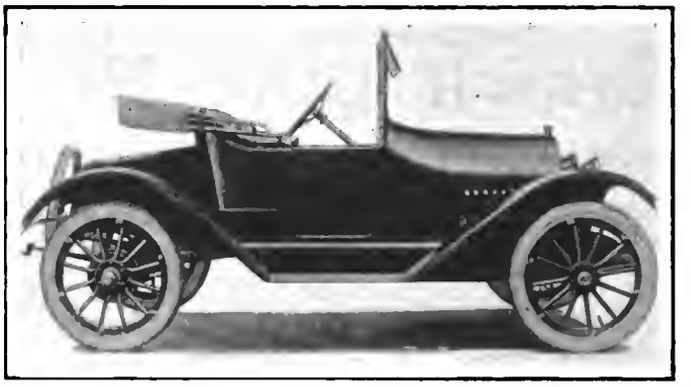
Lite starting motor, which is geared to the flywheel by means of the Bendix automatic starter drive. On the left and driven through gear connection with the camshaft is the generator, also an Auto-Lite unit. This generator has mounted on its top the ignition coil, and its rear end carries the vertical Connecticut ignition distributer which connects to the armature of the generator by helical gears. The flywheel is only semi-inclosed, due to the use of a form of bell housing which extends back from the crankcase and integral with it, until it meets the forward extension at the gearbox. Thus the lower half of the flywheel is exposed, as well as a portion of the upper part where the crankcase extension is cut out to reduce the weight without affecting the strength.

Peculiar to the Brush type of overhead valve engine, the rocker arms which transmit the upward motion of the push rods into a downward motion on the valves are not carried on rocker shafts as is usually the case. Instead, the rockers, which are steel pressings, have formed at their centers a socket which rests on a pivot and allows the same rocker motion that would be possible if the conventional form of shaft were used. The pivot is simply a threaded pin which seats in the body of the head, and its end protrudes through the top of the cover plate as already mentioned. Thus, adjustment of the rocker is obtained by screwing this pivot in or backing it out as the case may require. The valves are quite large for an engine of this size, having a diameter of 1¼ in., and being operated by a two-bearing crankshaft of generous proportions, the bearings of which measure ⅞ in. in diameter, by 2 7/16 in. long. It is driven from the crankshaft by helical timing gears inclosed in a compact manner.

As a great deal of the smooth running of any engine depends upon the sturdiness of the crankshaft and its support, the main shaft is of good size, having two main bearings, the front measuring 1 9/16 by 2 15/16 in. diameter and length respectively, and the rear of the same diameter, but 3 3/32 in. long. Although a moderately high-speed engine, it is fitted with a comparatively heavy flywheel of 12 in. diameter.

Splash Oiling—Thermo-Syphon Cooling

Lubrication of the motor is by splash, with the trough supplied by a plunger pump drawing its oil from the reservoir in the engine base. Each rod end dips into its trough and splashes the oil on to the several bearing surfaces in the customary manner. Simplicity is also obtained by the use of thermo-syphon cooling. The head casting carries the water outlet to the honeycomb radiator, and water enters the cylinder blocks at the center of the right side. A fan driven by belt from a pulley on the crankshaft is used, this having provision for adjustment of the belt tension by means of an arm attached to the forward end of the cylinder head.



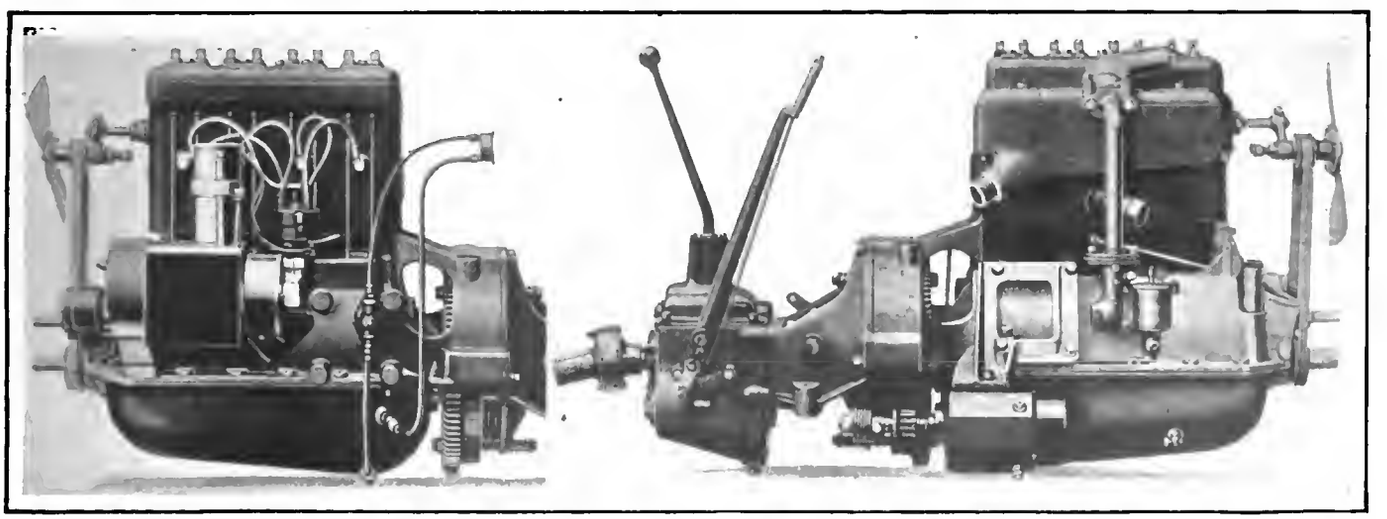
Monroe 1917 roadster which sells for $565. It has a four-cylinder 3 by 4¼-in. block engine and uses 30 by 3-in. tires

From the engine, the power passes through a simple dry-plate clutch having six disks alternately Raybestos and steel. Three selective speeds are afforded by the compactly-designed gearbox, which is mounted in unit with the motor, in the manner already described. The gears are of double heat-treated nickel steel, with stubby teeth to resist driving strains and sudden shocks. The gearshafts are carried on ball bearings. A ball and socket control lever is positioned on top of the gearbox proper, and the emergency brake lever attaches to the right side so as to play over a ratchet sector, also carried on this side.

Back of the gearbox there is a well-inclosed universal joint after which the driveshaft enters a torsion tube which incloses it to the rear axle. Drive is taken through the rear springs, while the torque is provided for by the propeller shaft housing. The three-quarter-floating rear axle affords a ratio of 4¼ to 1. Axles and pinion shafts are mounted on Hyatt roller bearings in conjunction with ball thrust bearings that take care of any end thrust. The axle tubes, which carry the car weight, are riveted into the two halves of the differential housing, and as a strengthening factor a truss rod passes below the housing between the brake drums.

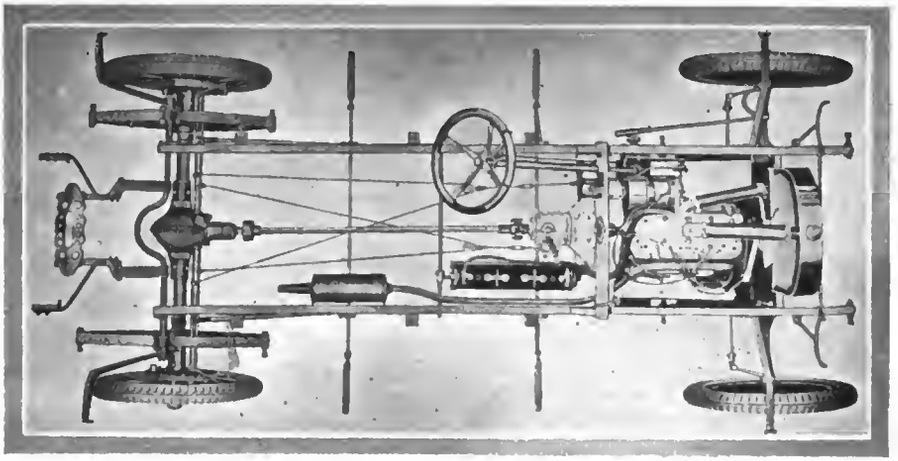
Rear springs, 46 in. long and of three-quarter elliptic form, are fitted at the rear, mounted outside the frame.

The new Monroe is painted a royal blue as a standard color and is said to be capable of speeds ranging from 3 to 50 m.p.h. on high gear. Tires are 30 by 3 in.



Both sides of the Monroe power plant, showing the arrangement of the manifolds, mounting of the electric units and the compact three-speed gearbox. Thermo-syphon cooling is used. Note the connection of the starting motor to the flywheel through the Bendix gear automatic starter drive

Brown Line Built on One Chassis



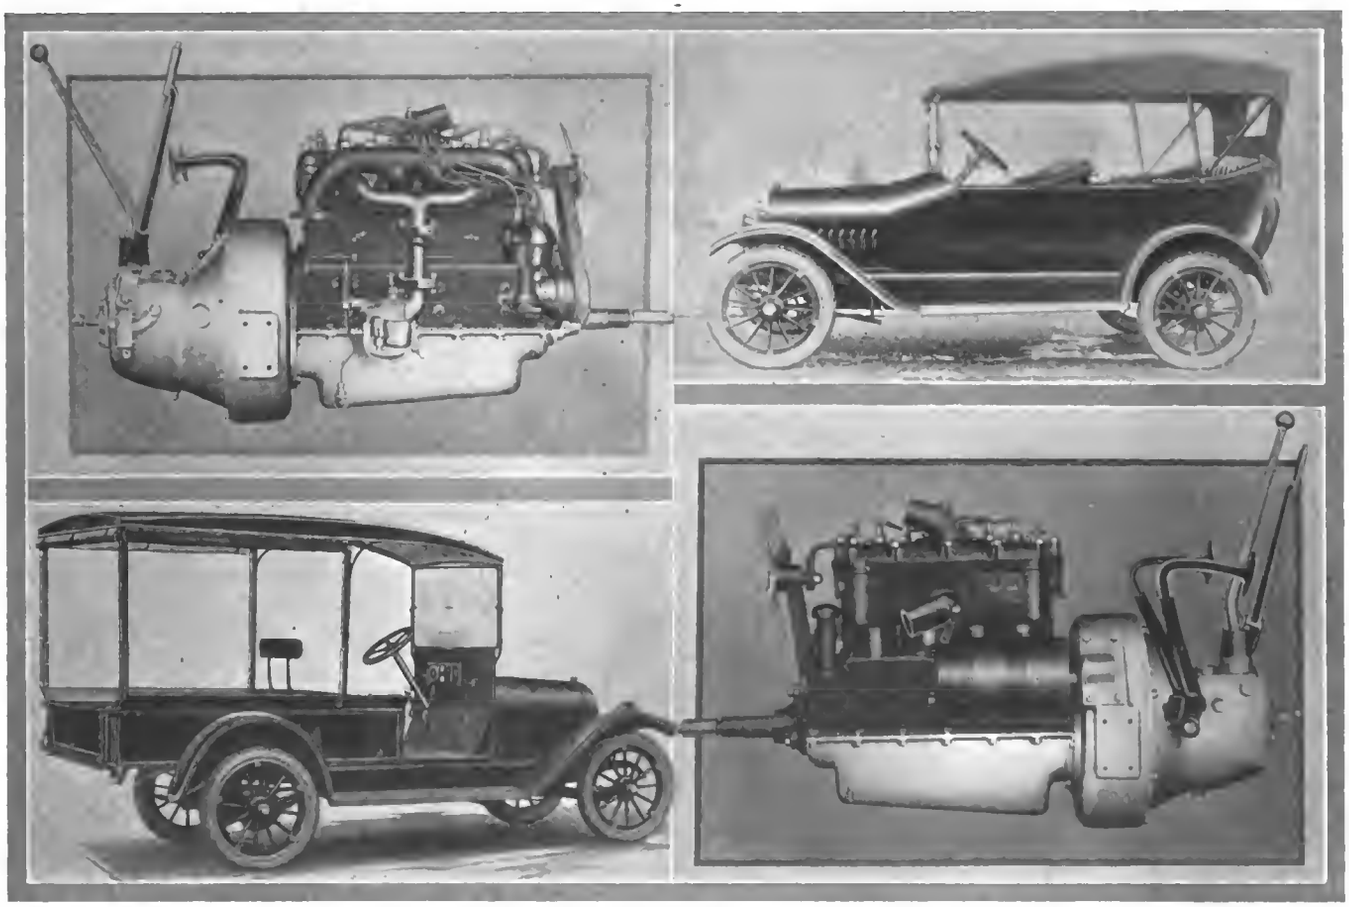
Chassis used for the Brown line of five-passenger touring car and delivery vehicles

A LINE of passenger and business cars has been put on the market by the Brown Carriage Co., Cincinnati, Ohio. This is an assembled product incorporating parts made by specialists among which may be mentioned the LeRoi engine, Walker-Weiss axles, Allis-Chalmers starting and lighting, Atwater Kent ignition, Kingston carbureter, U. S. L. storage battery, etc.

The LeRoi power plant is a unit construction incorporating motor, gearbox and clutch in a single housing. All four cylinders are cast in a single block and are of L-head shape with a bore and stroke of 3⅛ by 4½ in. The valves are on the right side and are completely inclosed. The upper half of the crankcase and the cylinders are in a single casting, while the lower half of the crankcase and the flywheel housing are in one piece and made from cast aluminum. The casting work is considerably simplified by the fact that the entire top of the cylinder is separate, being held in place by fourteen studs to the top of the cylinder with the joint sealed by an asbestos-copper gasket which prevents any leakage or loss of compression.

Large diameter valves are used but the lift is moderate, giving a quiet-running action; the valves are actuated by mushroom type push-rods which have an easy action on the cams. The bearings sizes are ample and the main bearings are all of die cast white bearing metal. The dimensions of the main bearings are 1¾ in. diameter by 2¾ in. length. The connecting-rod bearings are 1¾ by 2 and the camshaft bearings which are three in number are 1⅜ by 2 9/16, 1⅜ by 1⅝ and 1 3/16 by 1 11/16 in.

In order to preserve perfect alignment the flywheel contains a ball bearing which supports the front end of the gearset main shaft. Another point at which the bearings are carefully laid out is at the fan which also operates on



Brown touring car selling at $735 and delivery vehicle at $670 with LeRoi unit power plant used in both

ball bearings and which is adjustable by means of an eccentric insofar as tightening the fan belt is concerned. In the cooling layout the water inlets are large and are ample to take a 2-in. hose. The water is circulated by the thermo-syphon system.

Lubrication is by combined pressure and splash system with the oil delivered at either end of the engine by means of the oil pump and with the bearing taken care of by splash. Ignition is by the Atwater Kent system with automatic spark advance and in connection with the U. S. L. storage battery.

The balance of the electrical system is made up of the Allis-Chalmers motor-generator. With this system the instrument becomes a generator when the motor is running at speeds sufficient to charge the battery and becomes a starting motor when the gasoline engine is stopped and the starting switch closed. The characteristics of the engine are such that under ordinary conditions, the motor is cranked at more than 130 r.p.m. The storage battery floats on the line so that the lighting current is drawn directly from the battery.

A Kingston float feed carbureter is employed. This is a single adjustment type in which the only regulation is that of the needle valve governing the gasoline flow. The gasoline is fed to the carbureter by gravity flow and, as will be noted from the side view of the engine, the carbureter is placed low enough to insure a steady flow even on a steep grade. The carbureter is mounted on the right side of the engine together with both inlet and exhaust manifold and the ignition distributer drive, leaving the left side free except for the motor-generator, which is placed at the rear.

A multiple disk clutch is used lined with Raybestos. It is provided with six coil springs which insure perfect contact. The selective type gearbox is provided with three speeds and transmits the drive to a three-quarter floating Walker-Weiss rear axle. This is geared 4.25 to 1 on direct and the gears are of nickel steel with chrome nickel drive shafts carried on Hyatt high-duty roller bearings. The springs are of chrome steel with full elliptic rears. The front springs are conventional semi-elliptic. The wheelbase is 105 in. and the tire size is 30 by 3½ with non-skids front and rear. Demountable rims are used and one extra is provided on the touring car. Both Batavia and U. S. tires are used.

Full equipment is provided with the car, the top being a one-man mohair. The fenders are crowned and the running boards are covered with linoleum bound with aluminum.

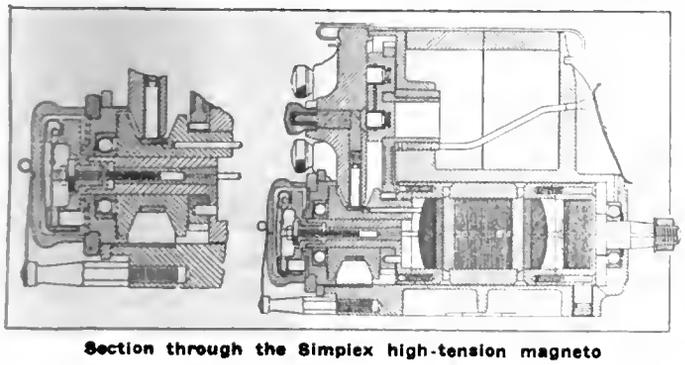
On this same chassis there is a five-passenger touring car at $735, a delivery car with 1000 lb. capacity at $675, a rear-door delivery at the same price and a general delivery open body at $670 including canopy.

Simplex a High-Tension Magneto

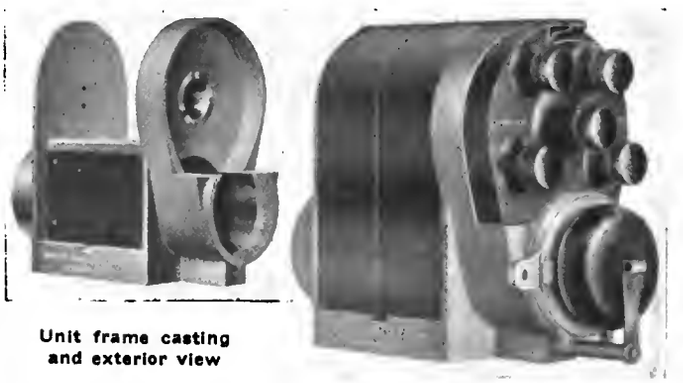
A NEW high-tension magneto has been put out by the Simplex Magneto Co., Inc., New York City. The men making up this organization have been connected with the manufacture of parts for European and American magnetos and have now organized to produce a complete instrument.

One of the features of the magneto, which is a high-tension type, and which in general is designed along conventional lines, is the simple interrupter which is so constructed that the centrifugal force of its moving parts is absorbed, thus maintaining an equality of pressure between the contact points and giving the same working conditions at high or low speeds. Another feature of the instrument is the ready accessibility of its vital parts, and the ease of disassembling to make minor repairs. An additional point of originality is the cast-in pole piece which is a laminated structure but so arranged that it does not have to be pierced by pins or bolts which would tend to increase the magnetic reluctance. The pole pieces and housing being integral, the air gap between the armature and field poles is very small. This tends to increase the intensity of the spark at low speeds, and, furthermore, since the poles and housing are integral they can be bored together to insure their alignment, and also renders the construction inherently waterproof.

As an example of accessibility, in removing the armature it is only necessary to turn a check nut and unscrew the armature ball-bearing cage. This allows the armature to be taken out of the frame without removing any of the parts.



Section through the Simplex high-tension magneto



Unit frame casting and exterior view

In connection with the armature an interesting feature is the construction of the condenser which is arranged with specially prepared insulating sheets between the individual foil laminations. This permits of a large number of sheets of useful foil, as the insulating sheets are very thin, giving an efficient indenture which tends to prolong the life of the points.

In general the Simplex magneto is a high-tension type carrying both the low tension and high-tension winding upon the single armature. The core is of laminated iron and on each side of this is a pole piece of the same quality of iron as is used in the armature. Holding this whole construction together are two bars which are firmly riveted into the pole pieces.

The details of wiring, etc., do not differ greatly from standard practice in high-tension magnetos. The low-tension winding has one terminal grounded and the remaining terminal is connected to an insulating plug allowing the path of the circuit to pass through the interrupter contact. The cam plate allows the spark advance to travel through an arc of 30 deg. and the interrupter mechanism is spring actuated giving a quick and snappy break of the primary circuit. The high-tension wire is attached to the distributer ring on one terminal and on the other to the ground by means of the common ground brush. The distributer mechanism is arranged for either four or six contact pieces, depending on the number of cylinders.

The Rostrum

Why Races Run Counter-Clockwise

EDITOR THE AUTOMOBILE:—Will you kindly advise the reason why practically all racing of every description is run in a direction from left to right, facing the track from the grandstand? It appears just as feasible for the entrants to face in the opposite direction, as racing cars, for instance, have the driver on either right or left side of the car which makes it apparent that racing in either direction should be practicable.

New York City. S. L. H.

—At the time the decision was made regarding the running of the races on the Indianapolis motor speedway anticlockwise it was for the reason that practically all the racing cars driven at that time had the steering column on the left-hand side of the machine and the driver's weight being on the left-hand side of the car naturally made the center of gravity and weight center a factor. Aside from this, it is natural to drive turns to the left with the right hand on the pulling side of the steering gear. If you are right-handed you will notice that it is always easier to control your car on the left-hand curve rather than a right-hand.

Conditions Due to Low-Test Gasoline

Editor THE AUTOMOBILE:—Is it not a fact that the low test gasoline of to-day causes the carbureter float to ride higher and consequently the level to maintain itself lower than with the gasoline of a few years ago?

2—In adjusting carbureter for this low test gasoline, in addition to changing level, is it advisable to use a slightly smaller jet?

3—Does not the action of atomization of gasoline in the carbureter cause the intake manifold to be cool, and is it not true that the richer the mixture, the cooler the manifold will keep? I have never seen an engine overheat due to a heavy mixture, but always with a lean one. Anyone can satisfy himself of this fact who has a Boyce Moto-Meter on the radiator.

4—Will not a manifold keep cooler with low test gasoline than with one of higher test and will not that coolness of manifold aggravate the difficulty of the carbureter to properly break up the fuel, unless heat is supplied in greater volume than formerly?

5—What is meant by low and high test? Is it density or specific gravity and what is the ratio between the two?

6—Is it true that if the slightest bit of acid used in refining oil should remain when graphite preparations of any sort are used mixed in the oil it will cause a stoppage in piping of oiling system?

7—Is it true that low test gasoline has more heat units and that a car will run farther on a given quantity than on the same quantity of high test gasoline?

Islip, N. Y. W. L. B.

—Yes, to an extremely small extent.

2—A smaller jet can be used sometimes but the difference must be very slight.

3—Yes, heat is required to vaporize the gasoline, and this is obstructed to some extent from the intake manifold. Obviously, the greater the amount of gasoline evaporated the greater the cooling effect on the manifold. Your experience regarding the effect of a heavy mixture on engine temperature is not normal.

4—A manifold will not keep so cool with low test gasoline, though it is also true that some heat is required.

5—Low and high test refers to the density. There is no ratio between the two, the words being used in a very loose way.

6—Yes.

7—The heavier oil contains more heat units per pound, but it is harder to make a good gas from it, wherefore it is usually impossible to obtain a greater mileage per gallon.

Oiling System of 1911 Pope-Hartford

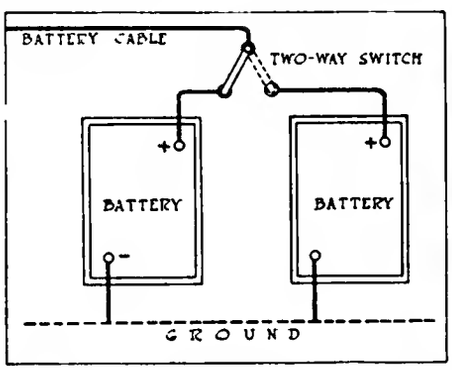
Editor THE AUTOMOBILE:—How does the oiling system on a 1911 Pope-Hartford work and how is same adjusted?

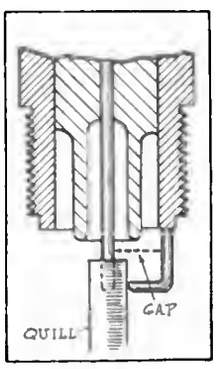
2—What is the correct timing of a 1914 four-cylinder National?

Providence, R. I. R. P.

—A mechanical oiler is located on the crankcase fitted with pumps, and an overflow standpipe. The bottom half of the crankcase is constructed with the oil reservoir beneath and cast integrally with it. In supplying the lubricating system with oil the mechanical oiler is first filled. The surplus oil runs into the crankcase, leaving the proper amount of oil in the oiler. The crankcase is also filled up to a level cock and holds about 3 gal. of oil. The pumps in the mechanical oiler force the lubricant to the cylinder and in addition a large suction pump sucks oil from the reservoir in the crankcase into the mechanical oiler, maintaining the proper level in this device.

Oil should be added through the filling tube every day or as often as necessary to bring the level high enough so that oil will run from the upper petcock which acts as a level gage. It is important that the oiler be adjusted so that one drop only at a time will show in the sight feeds to each cylinder. The leads are regulated by micrometer adjustment. The pipes run to the four cylinders and one adjustment takes care of the No. 4 cylinder and the sight feed on the dash. Individual sight feeds are fitted.





Left—Fig. 1—Connections for a two-battery ignition circuit, showing the use of two-way switch
Right—Fig. 2—Method of testing spark plugs by the use of a quill toothpick. By insulating the points the spark is made to jump a much larger distance than when in ordinary operation

The main crankshaft bearings are lubricated by splash, suitable pockets being cast on the inside of both ends and center of the crankcase for this purpose. The camshaft has four bearings all inclosed within the crankcase which are lubricated entirely by splash, suitable oil pockets, holes and grooves being provided for the purpose.

2—You do not mention the model to which you refer, but it is presumed that the information you desire is on the four-cylinder design. A timing diagram of this is given in Fig. 3.

Mistimed Spark Causes Power Loss

Editor THE AUTOMOBILE:—I have a C-36 Buick which does not have the ginger it used to have. In making hills on which it used to gain it now loses.

An expert on Buicks has ground the valve and cage seats, scraped the carbon out, seen that the cages were in right by taking the manifolds off, cleaned and adjusted the carbureter and adjusted the pushrods. Compression is good. Still there is no more snap to it. It also knocks when speeding up from 10 m.p.h. with spark well retarded. The bearings are all right.

Would burning out the cylinders and slowing down the timer stop the knock in picking up speed?

Lowville, N. Y. C. A. R.

—A possible explanation of your trouble is that the timer cam on the distributor shaft has slipped so that the spark is out of time. This a Buick service station will check up for you very quickly, if there is one near you.

You say the carbon has been scraped out, but if the cylinders were not removed to do this there will be a great deal left in which case burning out would be the cure.

Yet a third possibility is that the carbureter adjustment is incorrect.

A Method of Testing Spark Plugs

Editor THE AUTOMOBILE:—Referring to inquiry of E. E. F., Olmstead, N. D., in THE AUTOMOBILE for June 1, it may help him to know if his spark plugs are all right if he forces the spark to jump a decent gap. Naturally he cannot separate the points, but he can often introduce a quill or similar insulation between the points and make the spark jump a much larger distance. In most plugs it is possible to get a gap of ¼ to 5/16 in. or even more and this length of jump is pretty good evidence that the plug insulation will stand the voltage necessary to make the spark jump the point gap when under working conditions. Quills can be found at every poultry yard if in the country and quill toothpicks at many hotels. A piece of mica or celluloid can be used but not so handily on many forms of plugs.

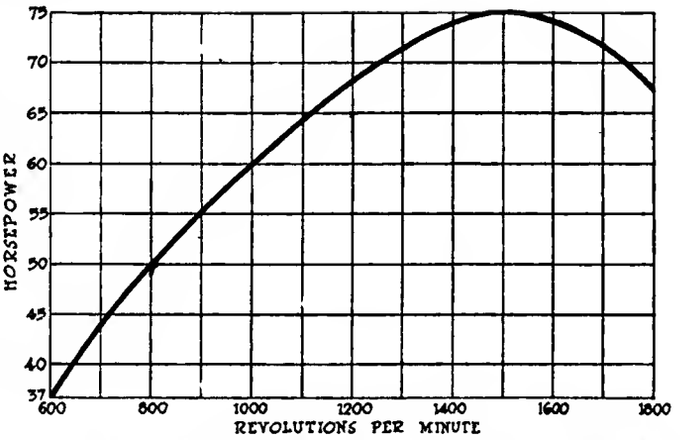

Fig. 4—Power curve of the 1910-1911 type 16 Lozier of 45 hp.

Crank and Eccentric Differential

It may interest your readers to know that the crank and eccentric differential described by Mr. Ormsby in his comprehensive article on differentials was invented by Edwin J. Gould, formerly of Colorado, but more recently of San Diego, Cal. Mr. Gould has spent much thought on the gearless differential problem and has recently made improvements to overcome some defects found in the original form.

Philadelphia, Pa. CHAS. E. DURYEA.

Wiring for Two-Battery Circuit

Editor THE AUTOMOBILE:—I have a car equipped with a double ignition system and am using one storage battery for starting on battery, electric horn, rear lamp, two dash lamps and one lamp inside of the car. As I have another battery, will you kindly publish a sketch showing how I can wire up these two batteries so that when one runs down I can switch on the other without taking one out or changing over any wires.

2—Kindly publish power curve of 1910 45-hp. Lozier.

3—Where can parts be bought for a 1905 Rochet-Schneider?

New York City. A. W. B.

—Presumably one terminal of your battery is grounded by a wire connecting it to the frame. In fitting the second battery it will be necessary to see that the corresponding terminal is grounded, that is to say, if you ground the negative terminal on the first battery it must be the negative terminal on the second battery that is also grounded. You can then readily use one battery or another by shifting over the wire attached to the positive terminal. To introduce a switch take the present battery wired to the middle point of a two-way switch and bring two wires from the two batteries attaching them to the other two contacts of the switch. Then by throwing the switch either one way or the other you can use either battery. The connections are precisely the same as those employed for an ignition switch which gives you either battery or magneto, as illustrated in Fig. 1.

2—Power curve of 1910 Lozier appears in Fig. 4.

3—THE AUTOMOBILE has had several requests for this information but has been unable to trace any stock of parts in America. It would probably be cheaper to have the parts made specially here than to get them from France.

The FORVM

LEAK-PROOF IS THE McQUAY-NORRIS PATENT TRADE NAME—ALL-YEAR CAR AND HUNDRED POINT SIX ARE KISSEL TRADE NAMES

Leak-Proof Is McQuay-Norris Patented Name

By L. A. Safford

Second Vice-President, McQuay-Norris Mfg. Co.

THE manufacturer of a nationally known and standardized trade-mark must of necessity jealously protect it. Our trade name, Leak-Proof, has been nationally standardized through extensive advertising and the phrase Leak-Proof is our own registered trade-mark.

Like many pioneers in a new field, this company has suffered through misuse of our trade-marked name, Leak-Proof, which applies specifically and only to the piston ring manufactured by this company. It is not a descriptive phrase pertaining to a type of ring, yet some automobile and engine builders who are departing from the conventional type of one-piece ring have described their ring equipment as being leak-proof or of a leak-proof type. The injustice of this is manifest.

Therefore, we will appreciate your giving publicity in the columns of THE AUTOMOBILE to this letter and the fact that there is no Leak-Proof piston ring except our patented, trade-marked product, which is not used by any automobile or automobile motor builder as universal equipment. Leak-Proof piston rings are sold only through jobbers and dealers for replacement purposes.

All-Year Car and Hundred Point Six Kissel Names

By H. F. Daniels

Kissel Motor Car Co.

ALL-YEAR car and Hundred Point Six are Kissel trade names. The first identifies the detachable top idea originated by Kissel. The second identifies a new and highly successful Kissel model recently introduced.

May we ask your co-operation against any who attempt to trade upon the reputation of our product by using either of these phrases?

We cheerfully acknowledge that it is largely due to the vigilance and sense of fairness of the press that All-Year car has not appeared extensively in connection with other cars.

We hope for this same vigilance and sense of fairness from you in regard to the Hundred Point Six.

Advantages of Metal Mesh-Type Running Boards

By M. K. Woodford

IN recent years most of the cars seem to be equipped with running boards of wood covered with linoleum or some similar substance, and after a comparatively short terminal service their appearance is usually far from a credit to the owner or manufacturer. Of course, some fastidious owners or operators of cars manage at the price of eternal vigilance to keep their running boards in good condition, but this is the exception rather than the rule.

Back in 1909 and even as far back as 1907, I remember a type of running board being in use which seems to me a much more serviceable and satisfactory construction than those employed at the present time. The boards to which I refer were made of strips of metal in zigzag fashion so that when the strips were placed side by side with their plane surfaces vertical they formed a sort of mesh. Two heavier metal strips formed the edges of the board and ⅛-in. bolts passing transversely through these and the intermediate strips secured them in place. Running boards built in this fashion were durable and of excellent appearance, having no linoleum covering to become streaked and spotted with oil or to stretch and bulge so that holes eventually appear.

The metal running board does away with the necessity for a scraper to remove mud from the shoes when entering the car and in case of the running board striking some object the metal strips are readily bent back into shape, thus saving the expense of the repair work necessary with the wooden boards when damaged. I would like to draw the attention of our car manufacturers to this minor but interesting feature of construction.

Car Needs Hand Brake in Alps

By M. Quesney

IN reading THE AUTOMOBILE for May 18, I find in the paragraphs on Current Topics an extraordinary Forum paragraph on the uselessness of the hand brake. Well, has the writer ever motored in mountains? If not, let him come in the Alps and try a dozen or more Alpine passes over 6000 ft. The glacier road, for instance, which goes to 8600 ft. or so, the last 4 miles 15 per cent grade with a round dozen of hairpin corners. The only sound and agreeable way I have found to coast down these roads is to engage second gear, switch off the magneto, shut off the gas and push the hand brake, more or less, so that you never come to more than 20 m.p.h. in the straight bits, then slow down at the corners with the foot brake, which is on the transmission and not on the back wheels. Of course, the average speed is very low, some 14 to 15 m.p.h., but you go there for scenery and not for mileage. Incidentally, my car is a small 7 hp., 56 by 120 mm. DeDion-Bouton, with a single seat and having a very short wheelbase, which is by far the best thing I have found for those roads.

Farm Motor Machines at British Show

Exhibition Curtailed by War Restrictions But Registers Growing Demand for Gas-Tractors and Plows

AT the 77th annual show of the Royal Agricultural Society at Manchester, England, the number of visitors rose to 149,000, as compared with 104,000 at the show of last year, at Nottingham, which was the first during the war. Previously the record attendance was 217,000 in 1897.

Though the number of exhibitors was larger than ever at the show as a whole, and especially in the live-stock department, the exhibition was not fully representative of the development in farm motor machinery, partly because manufacturers were busy with war work and partly by reason of restrictions ordered by the Minister of Munitions, excluding tractors applicable to other purposes as well as to agriculture. The resulting fragmentary character of the show is reflected in the reports of it, as contained in *Commercial Motor*, *Engineering* and *The Engineer*, from which the features and illustrations presented in the following are selected. In a general way it is notable that steam tractors no longer predominate absolutely over tractors or self-contained motor plows powered from internal-combustion engines.

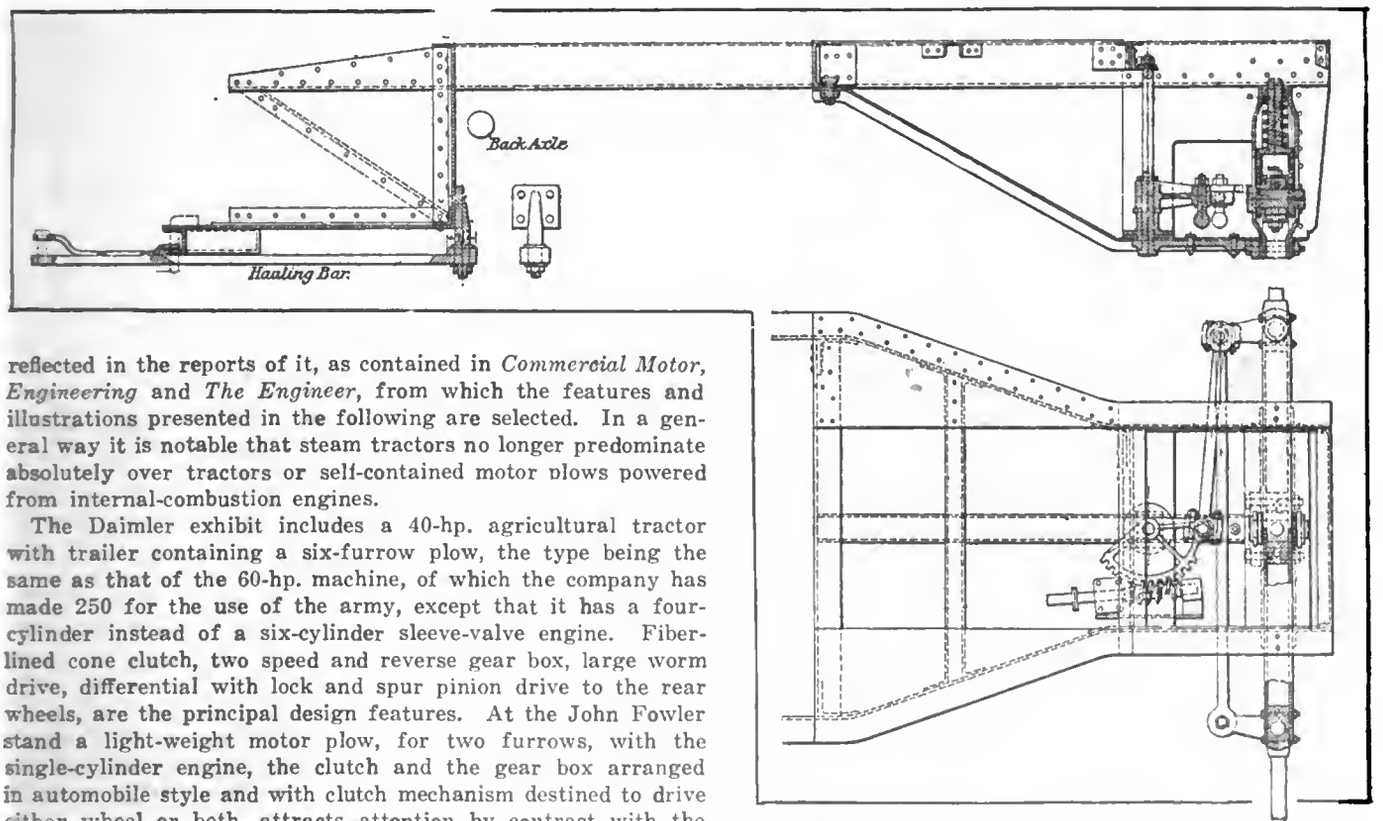
Fig. 1—The Omnitractor, a recent development in general-purpose tractors for use on farms

The Daimler exhibit includes a 40-hp. agricultural tractor with trailer containing a six-furrow plow, the type being the same as that of the 60-hp. machine, of which the company has made 250 for the use of the army, except that it has a four-cylinder instead of a six-cylinder sleeve-valve engine. Fiber-lined cone clutch, two speed and reverse gear box, large worm drive, differential with lock and spur pinion drive to the rear wheels, are the principal design features. At the John Fowler stand a light-weight motor plow, for two furrows, with the single-cylinder engine, the clutch and the gear box arranged in automobile style and with clutch mechanism destined to drive either wheel or both, attracts attention by contrast with the better known large Fowler units. Either wheel can be raised to ride on top of the land with the other in the furrow. The control is from the rear where a seat for the driver is accommodated on a castor wheel. A belt pulley is mounted on the engine shaft in front of the radiator.

The 24-hp., three-wheeled Ivel tractor is shown with a device for heating the fuel by the exhaust gas, so that kerosene may be used after starting with gasoline. The engine is a two-cylinder, horizontal-opposed located amidships on the off side and drives by silent chain to a countershaft and thence by roller chain to the differential on the rear axle.

The Martin Cultivator Company's two-furrow plow is the lightest machine with caterpillar traction belts. Either of these can be elevated.

The Omnitractor is a newcomer with many novel construction details, some of which are shown in the accompanying



Figs. 2 and 3—Showing built-up frame used for Omnitractors, supported upon front axle by helical spring, axle pivoted in its vertical plane, wheels steered on automobile plan

illustrations, Figs. 1 to 9 (from *Engineering* of June 30, where a full set may be found). A peculiarity is the extensive use of standard merchant bar steel and sections in popular sizes, the object being mainly to facilitate repairs, it is said. This four-wheel tractor weighs 3¼ tons and can apply a tractive effort of 2000 lb. at the wheel rims. The main features are as follows:

Engine, two cylinders, 6 in. bore, 9 in. stroke, giving 30 hp. at normal speed of 750 r.p.m. Starts on gasoline but can run on kerosene with water injection. Mounted over rear axle, transversely. Chassis entirely of merchant sections (Figs. 2 and 3). Three-point suspension of the frame, the front part being supported on a helical spring at middle of front axle and the axle pivoted. Ackerman steering by worm and sector, as shown.

Driving wheels, 5 ft. dia., 16 in. wide, all built up from sections without use of special forgings (see Figs. 4, 5 and 6). Front wheels, 3 ft. 6 in. dia., 8 in. wide. The drive by large cast steel spurgear wheel supported from wheel rim by four brackets.

Transmission entirely by spur gearing, bevels being avoided to escape necessity of maintaining accurate alignments. Transverse mounting of engine serves this plan. Moving part of clutch is mounted on sleeve which runs loose on engine shaft and at outer end carries belt pulley for driving farm machinery. To drive tractor itself a sliding pinion on this clutch sleeve can be thrown into engagement with gearwheel on differential. The engine speed is governed.

Gearbox gives 2¼ and 4½ m.p.h. forward and one reverse, operated by independent but interlocking levers, the locking device preventing improper operation. Emergency brakes are applied direct to drivers and will hold tractor on any hill.

Cooling system includes centrifugal pump drawing from bottom of fan-cooled radiator into which water flows from cylindrical tank on front end of frame containing large number of 2-in. tubes serving as flues for a draft induced by discharging engine exhaust through a series of jets below a chimney fitted above the top tubeplate of the tank. Loss of water said not to exceed 1 gal. per working day.

Fuel; provision made for heating the air on its way to the engine in order to run on kerosene, with by-pass and valves for switching from and to gasoline.

Differential (Figs. 7, 8 and 9); as stated before, bevels are avoided, and construction is therefore by spur pinions as shown. Locking by dog clutch shown to the right in Fig. 7, operated by lever provided on the foot-plate.

Starting gear on clutch sleeve is of safety type, causing release in case of backfiring.

The Overtime farm tractor weighs a little over 2 tons and has a two-cylinder horizontal engine, with bore and stroke 6 and 7 in., developing 24 hp. at 750 r.p.m. Many of this model, which is of American type and origin, were shown. An American-made tractor shown this year for the first time at the Royal Show was the Bull. The Wyles two-furrow motor plow was shown with no other material changes since last year than an enlargement of the cooling system and a provision for controlling engine speed by correcting the strength of the governor spring. The steam equipments exhibited differed little from those previously known.

Opinions on Different Traction Systems for Farm Work

APPARENTLY realizing that rapid progress in applying motor power to agricultural work depends on clearing up all doubts as to what system of machinery will give best results for a given set of working conditions, *Commercial Motor* presents interviews, one of which represents a decided preference for the cable system, another a conditional preference for the general-purpose tractor and a third perfect satisfaction with results so far accomplished with one of these. It is noted that the cable system advocate, Mr. John Allen, is governing director of the Oxford Steam Plough Company and has been identified with cable-ploughing for 40 years, meaning the system by which the plough is hauled to and fro by attachment to a cable passing around drums of powerful engines, one at each side of the field to be worked.

Condensed statements from each of these interviews are given herewith.

John Allen, advocate of the mechanical drum-and-cable system, says:

Plowing can be done more rapidly by cable than by any other method, so as to utilize favorable weather fully.

For cultivating, dragging and harrowing, traction by cable is acknowledged to be superior, because moving of the motive power over the already plowed land is avoided.

Traction plows are unable to compete with cable plows in quality and quantity of the work on hilly, heavy or clay land and on ridge-and-furrow land.

The field for the tractor-plow lies in work of a supplementary character to that done by cable. It is useful in the rush periods and for owners willing to limit their use to supplementary plowing, breaking up clover stubble and for power purposes, such as threshing.

The "farmer's small plowing set" was formerly much talked about, but now different types of engines are made for different jobs, in response to the demand.

Tractors will never be suitable for cultivating and subsequent operations.

American and Canadian conditions do not apply where it is important to get the largest yield per acre.

American and Canadian tractors are not built to stand up on hard roads and will not endure road-haulage in European countries where roads are hard.

A steam-plowing set (with cable) costs approximately $15,000. *A contractor can make profits with them because he can find work from mid-March to mid-November.*

Skilled labor, used to working with agricultural tractors, will not turn to ordinary farm work, and here lies a source of trouble.

Hereafter, if farm work cannot be done by mechanical means, it cannot be done at all.

Tractors, if light enough, should become useful for reaping and binding, as well as for plowing and stationary work. But the tendency is to make tractors heavier to secure increased output and robustness.

Mr. R. G. Patterson, prominent agriculturist and landowner not yet using motor power in the fields, says:

Mechanical means for cultivation are necessary, but I am not at all sure that a suitable and reliable machine is yet available.

I do not feel specially called upon to do pioneer work for the makers of agricultural machines.

A tractor for the average farmer should not weigh more than two tons, to avoid packing the land as it traverses it, and the price should be less than $1,250.

Engineers must decide how heavy the tractor must be to draw three or four plows or a large cultivator.

With a tractor the farmer can go on with his work when the weather is fit, and does not have to wait for a cable-plow contractor to get through with other work first.

Tractors must be light so as to be usable under the least favorable conditions of soil and weather without harming the surface. But nothing must be sacrificed to obtain lightness.

Mr. J. W. Bradford, who for 2 months has used 2-ton Overtime tractor on 480-acre farm recently taken over in bad condition from neglect, says:

Two shillings an acre covers operating cost, not figuring wages of two men, one on tractor and one on plow.

With a four-furrow plow operated from tractor's seat and arranged to lift each plow as it reaches the end of the furrow, the work can be done by a man and a boy.

I have made a hobby of plowing two or three acres after tea with the aid of my little girl only.

With a tractor you can wait till the good weather comes and then rush the work, while with horses you would fall behind on that plan.

The Portent of Electric Farm Machines

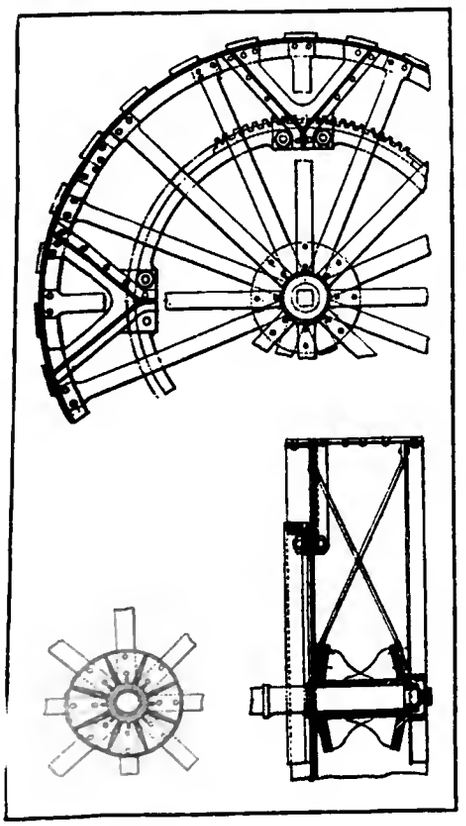
To Protect Sales of Cars and Trucks the Automobile Industry May Be Obliged to Lead Development of Agricultural Motor Machinery and Prepare to Manufacture a Type Adaptable to All Conditions

By Marius C. Krarup

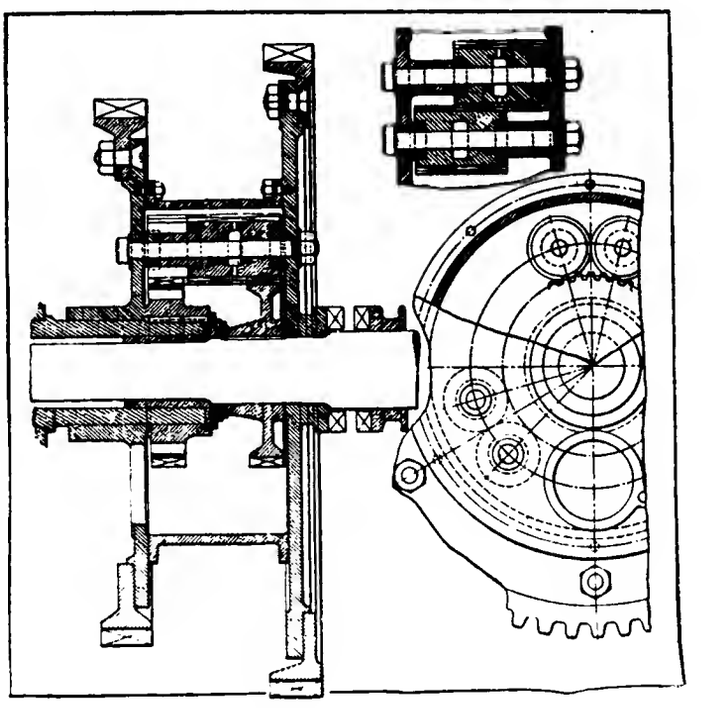
FOR several years descriptions and illustrations of mechanical design and detail in agricultural self-propelled machines have from time to time been urged upon the attention of automobile manufacturers, with a hazy idea that the collaboration of the automobile industry might result in benefits for all concerned. But it has generally been supposed that the decision as to what should be the type of the agricultural machine lay with the farmer and with the implement makers who have been in close touch with the wants of farmers for many years. It has come to be almost accepted that there must be many types of machines, differing radically in the means employed for replacing animal power and locomotion—apart from the necessary differences dictated by the many variations in the nature of the work for the sake of which the power and the locomotion are required. At the same time opinions are varying more and more as to what type of motor machine is most suitable for the average farmer, and on the basis of which the largest and most profitable, useful and interesting business can be created.

If it can be shown that the type which will win out is liable to throw the manufacture of cars and motor trucks for farmers into the hands of those who make farm machines of this type, the choice and development of this type suddenly becomes a matter of vital importance to the automobile industry, which does not wish to lose its rural trade and, on the other hand, will hail with satisfaction any development that promises to expand it. If a study of the present situation in the design and manufacture of farm machines supports the idea that the eventually prevailing type among these machines will be one—or only may be one—which will take its power from the farmer's automobile or from the motor trucks on the farm, provided the automobile and the motor truck can be and are made suitable for supplying it, no great foresight or imagination is required for discovering that the automobile industry will stand to lose or to gain greatly according to what action its members take at the present time in sizing up the situation.

In the account on the preceding pages of the Royal Agricultural Show at Manchester the emphasis is still on the



Figs. 4, 5 and 6—Construction details of driving wheels for Omnitractor. Hub a steel casting. All the rest built up from merchant sections



Figs. 7, 8 and 9—Spur pinion differential in Omnitractor; less sensitive to misalignment than the bevel pinion type

mechanical details of the "agrimotors" actually exhibited, but from the accompanying extracts of interviews one gets a rather vivid impression to the effect that the waiting and hesitating world is most deeply interested in the choice of the type and consents to examine the mechanical details, ingenious as they may be, mainly because they are helpfully suggestive in the effort for reaching larger and more important conclusions or, at best, because the practical situation is so urgent that an immediate choice must be made in order to get needed work done somehow.

An automobile manufacturer, whether he contemplates to manufacture farm machines, or merely to protect his automobile business, is called upon to go more energetically into the question of type than the prospective user of agricultural machines, to whom any machine may be better than none. Some ideas come up in connection with this subject which may serve to show how relatively unimportant are all matters of mechanical detail in tractors or motor ploughs so long as it is doubtful if a suitable basis for developments has been discovered.

Need of a Basis

Real automobile manufacture began only when Levassor had devised a design having the peculiar property that improvements could be added piecemeal without ripping the previous construction to bits. It was perfectible.

In comparison with automobiles the new field, whose magnitude and promise everybody now sees, presents the enormous difficulty, for the start, that the output must at once be clearly superior in operating economy to the system of farm work so far employed—including investment charges—but also the important easement that machines can be marketed if they only fulfill this first condition for one of the many greatly varying sets of circumstances and classes of work for which agricultural machines are wanted. The easiest requirements, however—those relating to large estates with level or gently undulating land almost free from stones—are precisely those which have been met by the steam plough and farm tractor industry as it exists to-day, and which no other concern in this line can figure on without also figuring on the sharpest possible competition backed by valuable experience. In this section of the market a new concern must at once be able to offer efficiency and economy markedly better than obtained from the machines now sold. If it cannot do that—and this in itself would mean a new type—it has practically only the difficult end of the market to depend upon, for which nobody so far has been able to devise machines that are or can be accepted as final in type or detail.

It is therefore with regard to machines for difficult mechanical or economical conditions that every prospective newcomer must view the subject so sharply in order to make sure that the type he selects to manufacture has the principle of growth in it and is not one which will be scrapped the moment a more generally adaptable type makes its appearance. And, if he does not contemplate to enter upon new manufacture, it is also from this section that the type may arise which may interfere with the business of selling cars and trucks to farmers. Evidently the coming of such a type should be recognized as long in advance as possible. When industrial activities begin to cluster around it, the opportunities for embracing it get scarce. And it is of course more profitable to embrace than to fight it.

The British Show gives but few clues that can be helpful in looking out for what there may be in store of this nature. Steam tractors, gas tractors, cable system, self-contained motor ploughs in different sizes and recourse to the caterpillar traction system—these make the list of expedients mentioned as actual.

The highly desirable adaptability of every machine unit to MANY agricultural conditions is not strongly represented in any of these types. But the eventual type must have that, since not only are there many kinds of farms but each farm as a rule has many different conditions to meet; on upland, low land, rough land, heavy soil, light soil, level land, hillside, and in the varieties of crops which are cultivated.

Designer's Guide Book Wanted

Probably not one-tenth of the things to be considered in a farm machine equipment has ever been brought home to the machine designer in such form that he can keep his mind on them all at the same time and can allot to each of them its proportionate value in the general scheme. And probably one of the most fundamentally useful things that could be done at present would be to arrange a competition for the production of a slender volume—say a book of 200 octavo pages—setting forth in the most orderly and convincing fashion the agricultural requirements to which farm machines should conform; and setting forth also, partly for the information of farmers, an analysis of those mechanical methods for working the soil which differ from customary plowing, harrowing, dragging, weeding, etc., etc. These may be better adapted for operations by machinery than the old methods, which are so clearly an outgrowth of the use of animals and cheap human labor and should not be accepted as a necessary or permanent handicap for machine design, though of course they should not be discarded lightly or prematurely, as so many people know how to work with them and are disinclined to abandon them.

The adaptability of a type would clearly be greatly enhanced if it included that either old or new soil-working tools and methods could be used with it without radical transformation of the basic equipment. The hoe has always produced better crops than the plough, and the motor hoe is in the ascendancy in France, Bavaria and Austria.

An Adaptable Type

With experiments in mind which have been made in this country, and also in Germany in connection with an illumination scheme for night work in the field, it seems possible to sketch a type which gives more promise for the large majority of farmers, big or small, than any of the types exhibited at the Royal Show, and which, in addition, bids fair to interest automobile manufacturers greatly, for better or worse. This type means an equipment depending for power on the internal-combustion motor and on electric transmission for reaching the machines in the field.

The power unit may be the motor truck of general utility on the farm or an automobile otherwise used for personal transportation. This power unit itself would have electric drive. The generator would have connections not only to the electric vehicle motors but also to insulated feed wires wound upon one or two dismountable reels and terminating in properly safeguarded attachment plugs. The field units would be (1) a light four-wheeled carrier with swiveled front axle, two front driving wheels (with expansible rims and projecting tines, the tines being normally kept shorter in proportion as wheels were expanded to larger diameter, making higher gear, but susceptible of independent adjustment to allow one wheel to be made larger than the other, a differential gear compensating them, and completely retracted within wheel for road travel) and one or two electric motors to drive the tined wheels and also a main shaft arranged to be connected, when required, at different gear ratios to different tools; and (2) the agricultural tool of whatever kind, highly specialized for its work, to be attached as a plough or dropped into the carrier unit and connected—rigidly or flexibly, as the case might demand—to the main shaft just referred to at the gear ratio suitable for its work.

With the power unit remaining stationary, the feed wire or wires would be paid out from the reel or reels as the work-

ing units advanced over the soil and, having suitably swiveled attachments, would be rewound as the working units returned, the reels being of the largest practicable diameter to minimize wear of the wire insulation. A lasting and yet not bulky or heavy insulation would here be one of the few things yet to be devised.

Equipments somewhat of this nature—excepting little but the division of the field machine into a general electric tractor unit and the interchangeable mechanical soil or harvest tool—have been found suitable in their general features for agriculture as well as for lumbering in this country and in Canada, but have received little public mention. But the rapid growth in the demand for farm machines, as well as the prominence accorded to other types, now seems to call for all the mental energy that can be brought to bear to decide the question whether this type of equipment is not more adaptable to all kinds of soil and surface and to all kinds of work than any other, and especially than either the mechanical cable traction system or the universal tractor system. As it can be worked with a movable trolley wire, charged from the power unit (thereby avoiding the question of special insulating material), just as well as with a trailing feed wire, it is not limited to fields of small dimensions.

Perhaps it may prove a matter of the greatest importance in the choice of the type which shall predominate, that the millions of soldiers who will return to farms after the end of the European war will all be familiar with the erection of electric wire posts and with the careful handling of heavily charged wires.

The Urgency

The special interest of the electric equipment to the automobile industry, over and above any attaching to any other type that has been proposed, seems to be beyond doubt, since its general acceptance would involve the manufacture of farm automobiles and farm trucks on a plan suitable for making the power of such vehicles useful all the year round and almost all the time, thereby adding to their value and the universal demand for them. For the farmer it should be a valuable though subordinate advantage and convenience to be able to hang up an electric motor to drive a shaft at any place on his farm where power may be temporarily wanted, as for churning, milking, baling, conveying, pumping, etc., and to arrange readily for electric lighting in house, barn or field.

The North Adjustable Cantilever Spring

Editor THE AUTOMOBILE:—Perhaps you will allow me, as the inventor of the Adjustable Cantilever Spring described in your issue of June 1, to reply to your Reviewer's criticisms of the mathematical treatment of the design.

Mr. Krarup appears to object to my considering the spring as two separate portions. I would point out to him that though the fulcrum may be moved during the process of adjustment from the position above *B* toward *D* the clip remains attached to the *same* point on the spring. The only source of error in the assumption that I have made lies in the fact that it is impossible to estimate accurately the exact effect on the portion of the leaves embraced by the clip, of the pressure of the gripping wedges or set screws.

I remember seeing a fairly elaborate discussion of the effect of buckles or clips on the theoretical deflection of the spring, in the American automobile press some time ago. In my experience, the effect of such a clip as shown is to make the spring about 2 per cent stiffer than it would be if the clip were replaced by a single bearing point. This was specifically mentioned in the article, and it is only in this respect that the mathematical treatment given is based on approximation. As a matter of fact, every spring that has been made with my adjustment has given deflections which agree with the calculated deflections within 5 per cent, for all positions of the adjustment, and considering that this variation includes that caused by inaccuracy of the thickness of the leaves I consider that result proves in a practical way that my mathematical reasoning is correct. If your Reviewer will bear in mind the point mentioned at the commencement of my letter, viz: that the clip is always attached to the same portion of the spring, he will see that my mathematical reasoning does not involve any unfounded assumptions, and is quite logical.

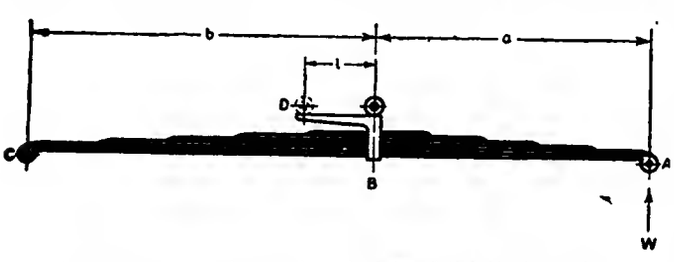


Diagram illustrating main principle of the North spring

The method of calculation of the deflection at the point *A* from the deflection at the point *C* is absolutely correct, as it is simply a question of taking the moments about the point *D* to obtain the displacement at *A* which a given deflection at *C* would cause. In this part of the calculation, it is merely a question of leverage and of relative movement. The fact that point *C* is anchored instead of being free to deflect makes not the slightest difference to the stresses and deflections of the spring itself, and I think that if Mr. Krarup takes the opportunity of looking further into my mathematics he will find that his criticism of my reasoning is unjust and unfounded. If he can show me a simpler way of calculating these springs, I shall be only too pleased to learn from him, but I confidently assert that he cannot show me a more accurate method.

London, June 28, 1916. O. D. NORTH.

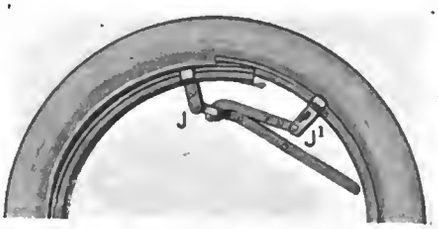
Mr. M. C. Krarup is agreed with Mr. North that the tests of his spring may testify to or toward the correctness of the mathematical demonstration. His objection was to accepting the mathematics in advance as in themselves convincing. In fact, he offered reasoning to the effect that the mathematics were superfluous for proving that the stresses arising in the spring must be acceptable, leaving in contest only the claim to accurate correspondence between the premises accepted for the mathematics and the physical realities of the spring. He cannot agree that it is self-evident that a stress transmitted from the free end to the anchored end, and there resulting in a certain flexure must cause an additional deflection of the free end in exact proportion to the leverages involved. He would expect the real deflections to fall somewhat short of those calculated in this manner. But he would accept tests showing that only 5 per cent of flexibility is lost. He would ask if such tests show the discrepancy not exceeding 5 per cent, mentioned by Mr. North, coming always on the side of reduced flexibility and whether the length of the front-end shackle influences the result. Such test results could then be incorporated in all cantilever spring mathematics, it seems.

With regard to other points the reader is referred to THE AUTOMOBILE of June 1. All points specially mentioned in Mr. North's letter were understood then as now. Mr. K., however, wants to add his sincere thanks to Mr. North for his very interesting treatment of an opportune subject, and does not think that a little difference of opinion *as to when the mathematics of the case begin to become convincing* involves any injustice to Mr. North.

ACCESSORIES

K. P. Universal Rim Tool

DESIGNED for use on rims of the transversely split type, such as the Baker, Stanweld, Kelsey, Detroit, etc., this tool makes their operation both quick and easy. It locks the rim in a collapsed position while the tire is being removed or replaced, pulling the joint on the Baker type down and sideways to clear the valve stem and opening the joint on rims which, like the Kelsey, use an interlock. The manufacturers state that it does not slip, spring the rim out of shape or throw all the strain on one point of the rim, but gradually pulls it all the way around. Tube-pinching is impossible, as the tire slides easily over the rim without the use of forcing tools. In removing a flat tire from the rim jaw J is clamped 4 or 5 in. from the split end of the rim that is to be pulled under. Jaw J1 is then clamped as far from J as the handle of the tool will permit before striking the rim. With rims of the Stanweld type the joint is broken with the screwdriver and the handle pulled over to the position shown in the illustration, which locks the tool, freeing the tire. With the Baker type the handle is pulled sideways until the rim clears the valve stem and lugs. In replacing the tire and locking the rim the tool is capable of forcing the joint together, as is sometimes necessary when the bead of the tire is undersize. The tool is practically unbreakable, being made of cold-rolled steel, and weighs only 3 lb. It sells for $2.—K. P. Mfg. Co., 250 West Fifty-fourth Street, New York City.



K. P. Universal rim tool

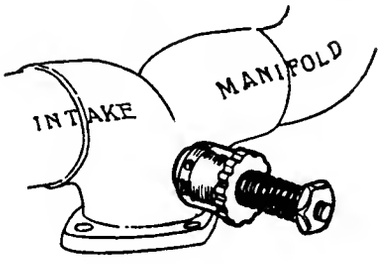
Cantilever Shock Absorbers

The Forgesteel cantilever shock absorber for Fords consists of a lever which takes the place of the spring shackle, to the end of which a long coil spring running to the frame is attached. A single lever set costs $8 and double lever, $10.—Home Light Co., 3353 Milwaukee Avenue, Chicago, Ill.

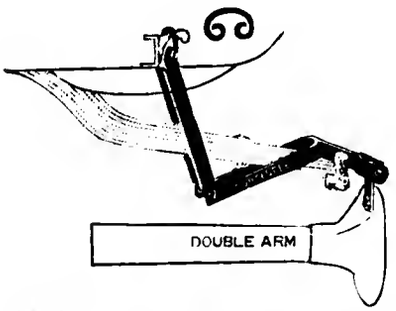
Right Gasoline Saver

The Right gasoline saver is in principle an automatic relief valve that attaches to the manifold and admits additional air to the cylinders in greater or less amount, according to the speed and load of the engine. The air intake is controlled automatically and admits additional air to the cylinders only when the engine is not pulling hard—that is, when the car has attained the desired speed. The valve remains closed while the engine is accelerating, so that it does not decrease the power of the motor when increasing the speed or in going up hill. When properly adjusted it does not interfere with the idling of the engine, while also it will fit any manifold. The manufacturer guarantees a saving in fuel of 30 per cent, and says that in tests the device has shown a saving of more than 60 per cent. It can be installed in 30 min. It lists at $5.—Right Motor Specialties Co., Chicago, Ill.

Legalite headlight lens



Right gasoline saver



Cantilever shock absorbers for Fords

Post type Evenlite

Legalite Headlight Lens

The main principle of construction in the Legalite, which is a multiple-prism lens, is that the lens consists of several types of prisms. Because of this the light is not diffused, while no glare is possible, the beams being sent downward and ahead, shining across the entire width of the road. It has been shown by tests that the Legalite device throws a driving light from 250 to 500 ft. ahead, and yet the light is at no point more than 4½ ft. off the ground. It is stated that the lens, which replaces the ordinary headlight lens, gives 25 per cent more light than the latter. Up to 8½ in. diameter the Legalite sells for $2.50; 8½ to 10½ in., $3; 10½ to 11⅛ in., $4.—Legalite Corp., 117 Boylston Street, Boston, Mass.

Post Type Evenlite

This device is designed to give headlights of constant brilliancy on Ford cars regardless of speed. It is stated at 7 m.p.h. it gives five times the standard Ford light, at 10 miles, 3 times the standard, at 15 m.p.h., twice the standard and at 20 miles and over, it is constant regardless of engine speed. The post type requires less than 30 min. to install and is supplied with two lamps, clamps and screws as well as with necessary wiring. The hood type sells for $4 and the post type for $6.—St. Louis Electrical Works, St. Louis, Mo.

Schultze Tire Tool

This split rim tool can be adjusted to fit any rim, straight side or clincher, from 30 by 3½ to 36 by 4½ by altering the position of the thumbscrew in the adjusting holes in the cross member, which is in two parts. The expanding mechanism is a simple toggle joint which operates to open or close according to the lever motion. Price $2.50.—Schultze Machine Shop, Chenoa, Ill.

Repair Gears and Parts

Repair gears as well as various other parts such as driving shafts, differential cases, bearings, etc., for more than 100 makes of cars, are furnished by the Auto Gear & Parts Co. These parts are kept constantly in stock for immediate shipment.—Auto Gear & Parts Co., 1777 Broadway, New York City, 1461 South Michigan Avenue, Chicago, 275 Marietta Street, Atlanta, Ga.

The South American Trade

IN the last 10 months South America has given our makers a taste of the possible ability of Argentina and parts of Brazil and other countries to purchase low-priced U. S. A. cars for farm use, a field hitherto very little exploited in these countries. The market is to-day a really appetizing one, but the question is, will it remain such after the termination of the war, when the time arrives that European countries can step back into the harness and pick up the reins of South American business that laid down on Aug. 1, 2 years ago.

Selling to the farmer in Argentina is in reality a new business, as the European car that dominated the South American field for nearly 20 years was largely sold in the cities. Europe has been watching with naturally covetous eyes the rapidly increasing sales of our cars in the country and reports from different countries suggest that after the war Europe may be much better fitted to compete with our low-priced cars than she was before the war. France is reported to be forming a $50,000,000 company to build low-priced machines on a great production scale. Some months ago reports leaked through from Germany that a similar project was under way there, and with the progress shown by England in various lines it would not be surprising if she, too, were engaged in like plans.

It seems certain that competition after the war will be keener than ever before and if the U. S. A. prices can continue to be much lower than European prices as in the past then there can be no doubt that our cheap cars will dominate the South American field as they are dominating other fields. But if Europe really meets us in price then we will be face to face with death-dealing competition because with our lack of U. S. A. ships and our poor exporting ability Europe can handle freight rates to suit its convenience and what advantages we gain by cheaper methods of manufacture, etc., will be offset on the freight question. There is at present sufficient difference in freight between Europe and South America as compared with U. S. A. and South America to indicate that with the war over, there would be a still greater difference. The U. S. A. ability to dominate the automobile market in South America will be very largely dependent on shipping rates. That is the only factor beyond the direct control of the automobile maker, and one that he must watch.

Farm Tractor Opportunity

THAT the sale of the modern type of small farm tractor is going to rest more or less with the automobile dealer has been indicated by the strong movement in their direction shown at the first tractor demonstration in Texas. Already many tractor makers have signed with large automobile distributors for large territories and more announcements of similar deals are being made every day. The tractor maker has been studying the dealer question carefully since last January, in fact before. At that time the tractor show in Kansas City was held the same week as the automobile show for the ostensible purpose of getting as many automobile dealers as possible to visit the tractor show. The object was partly accomplished, in fact, many automobile dealers signed for tractor territories at that time. Since then a vigorous campaign has been carried on and tractor makers have been keen students of the possibilities of the automobile dealer becoming the tractor dealer.

In our large agricultural areas the automobile dealer has for several seasons reported that he has been selling 75 to 95 per cent of his automobiles to the farmer. The automobile has been an unexpected asset to the farmer. He has been tied closer to the automobile dealer by the transaction and there is no more logical person to handle the tractor in our agricultural states than the up-to-date dealer.

Not all automobile dealers will be tractor dealers. Some are not qualified for the work. Some handle cars that do not suit the agricultural trade. Others are not adapted to handle the farm business. There will be many good implement dealers who will take their place in the tractor dealer field. The ultimate dealer of tractors is bound to be a compromise. But to-day the automobile dealer who has not looked into the tractor field for territory is overlooking a good opportunity. It is a certain business. The question for him to settle is, "Am I capable of handling the business?"

100,000 at Tractor Demonstrations

Oklahoma and Texas Farmers Crowd Into Dallas—Automobile Dealers Interested

By S. P. McMinn
Staff Correspondent

DALLAS, TEX., July 22—Demonstrating since Tuesday to interested crowds totalling over 100,000 and marked by many sales and even more agencies established, the first national tractor demonstration, participated in by nearly 100 machines representing some thirty manufacturers, came to a close here last night.

The farmers of Texas have flocked to the demonstration in numbers that have truly astounded those who expected a big attendance.

Car Dealers in Evidence

It is a significant fact that dealers and garagemen are taking such great interest in the demonstration. While manufacturers of tractors are plainly uneasy in their minds as to who ultimately will handle the tractor—automobile dealer or implement man—there seems no doubt but that the tractor maker will have to look to the garagemen for his service.

The demonstrations this year are being run in an entirely different manner from those of years gone by. The competitive spirit is entirely lacking and instead the whole affair is a demonstration in the purest sense of the word.

As an exhibition it is not unlike a great automobile show except that in every instance all the tractors are operating on gasoline and kerosene. Each exhibitor has a big tent; few of them have provided sawdust, and in each tent there is from one tractor to half a dozen.

Each day the machines are started running about 8 o'clock in the morning and few of them are stopped, except occasionally to replenish fuel, until 6 at night. Even during the plowing demonstrations the exhibition machines are permitted to run, often without attendance of any kind.

In this respect it is a tribute to their designers, that, in spite of the terrific heat, which during the first part of the week was as high as 103 deg., none of the machines evidenced any inclination to steam.

The public demonstration is started each day promptly at 1 p. m. At 12.15 all of the tractors leave their respective tents, and, towing the implements that will be demonstrated, make a great, noisy procession to the demonstration field, which is perhaps half a mile from the tents.

The demonstration is being held on what is known as the Caruth farm, a great tract of land giving about 1200 to 1500 acres on which to manipulate the tractors. Each tractor manufacturer has allotted to him each day a strip of land, the size of the strip being proportioned to the size of the tractor to be demonstrated and the number of plow bottoms it will pull.

Every tractor operator must start his machine at a given signal and continue to plow until all his land has been finished. This, of course, promotes some friendly rivalry between the various companies, but this is the only spirit of competition there is.

No restriction is placed on the kind of fuel employed. A maker may use either gasoline, kerosene or distillate, though up to to-day only one maker has been doing any plowing with the latter. But each maker must procure his fuel from a designated source, so that there may be no doubt of its gravity.

Most of the machines in use have been burning kerosene. On the first day, when there were some forty-four machines on the field at the same time, twenty-seven of them were operating on kerosene as against seventeen operating on gasoline.

The fuel problem does not appear to worry the farmer greatly in Texas. Gasoline is at present selling for 19 cents per gallon, but he can get kerosene from 7 to 10 cents. All manufacturers are taking kerosene into consideration.

During the week a large number of contracts have been signed and though few manufacturers care to make public the names of new dealers and distributers they have no hesitancy in saying that wherever it is possible they invariably prefer to do business with the automobile dealer or the garageman.

The accessory exhibit is one of the most interesting tents on the grounds. That there is a market and a big one for accessories there can be no doubt, for from the engine back to the transmission gear there is not a great deal of difference between the tractor and the automobile. Exhibitors:

TRACTOR EXHIBITORS

Waterloo Gasoline Engine Co., Waterloo, Iowa.—24 hp. kerosene; drawing one 10-ft., 10-disk harrow with one 10-ft. grain drill.

Standard-Detroit Tractor Co., Detroit—10-20 hp., gasoline, drawing one 4-gang Sanders disk plow.

Simplex Tractor Co., Minneapolis—10-20, gasoline, drawing one 4-gang La Crosse plow.

Rock Island Plow Co., Rock Island—10-20, gasoline, drawing one 4-gang Sanders disk plow.

Peoria Tractor Co., Peoria—8-20, kerosene, drawing one 4-gang Sanders disk plow.

Parrett Tractor Co., Chicago—12-25, gasoline, drawing one 4-gang Sanders disk plow.

Nilson Farm Machinery Co., Minneapolis—24-35, gasoline, drawing one 4-gang La Crosse plow.

Moline Plow Co., Moline—6-12, gasoline, drawing two 14-in. moldboard and two disk plows.

Twin City Tractor Co., Dallas—15-30, kerosene, drawing 6-gang Sanders disk, 40-60, kerosene, drawing 18-gang Sanders disk; 15-30, sub-soiler, drawing 32 12-in. spades and 3-gang Sanders disk plow.

Bates Tractor Co., Lansing—13-30, kerosene, drawing 4-gang Sanders disk plow.

International Harvester Co., Chicago—15-30, Titan kerosene, drawing 6-gang Sanders disk; 12-25, Mogul, kerosene, drawing 5-gang Sanders disk plow; 10-20, Titan, kerosene, drawing 4-gang Sanders disk plow; 8-15, Mogul, kerosene, drawing 3-gang Sanders disk plow; 8-16, Mogul, kerosene, drawing an Osborne disk harrow with tandem attachment; 10-20, Titan, kerosene, drawing two Kentucky 10 x 7 grain drills; 12-25, Mogul, kerosene, drawing 3 Webber wagons.

Holt Mfg. Co., Peoria, Ill.—25-45, gasoline, drawing 12-gang Sanders disk plow.

Happy Farmer Co., Minneapolis—8-16, gasoline, drawing 3-gang Sanders disk plow.

Hart-Parr Co., Charles City, Iowa—15-30, kerosene, drawing 3-gang La Crosse disk plow; 18-35, kerosene, drawing 8-gang La Crosse disk plow; 30-60, kerosene, drawing 10-gang La Crosse disk plow.

Emerson-Brantingham Co., Rockford, Ill.—12-20, Model L, kerosene, drawing 4-gang disk plow; 12-20, Model Q, drawing 4-gang disk plow; Big Four, 20, distillate, drawing 7-gang disk plow.

Denning Tractor Co., Cedar Rapids, Iowa—10-18, kerosene, drawing 3-gang Sanders disk plow; 10-18, kerosene, drawing John Deere pulverizer and harrow.

Sandusky Tractor Co., Dallas—15-35, kerosene, drawing 6-gang La Crosse disk plow.

J. I. Case T. M. Co., Racine—9-18, gasoline, drawing 3-gang Grand Detour disk plow; 10-20, kerosene, drawing 4-gang disk plow; 12-25, kerosene, drawing 6-gang disk plow; 20-40, kerosene, drawing 10-gang disk plow.

Wallis Tractor Co., Racine—26-44, gasoline, drawing 8-gang Case disk plow.

Bull Tractor Co., Minneapolis—7-20, gasoline, drawing 3-gang Sanders disk plow.

Avery Co., Peoria—5-10, kerosene, drawing 2-gang Grand Detour disk plow; 8-15, kerosene, drawing 4-gang John Deere disk plow; 12-25, kerosene, drawing 6-gang Rock Island plow; 18-35, kerosene, drawing 8-gang Rock Island disk plow; 25-50, kerosene, drawing 12-gang Rock Island plow.

Avery & Sons, B. F., Louisville—10-20, gasoline, drawing 2-gang Avery disk plow.

Allis-Chalmers Mfg. Co., Milwaukee—10-18, gasoline, drawing 3-gang John Deere plow.

Advance Rumely Thresher Co., La Porte—30-660, kerosene, drawing 14-gang Sanders disk plow; 15-30, kerosene, drawing 8-gang Sanders disk plow; 12-24, gasoline, drawing 3-gang moldboard plow.

Ford Tractor Sales Co., Minneapolis—8-16, gasoline, drawing 3-gang Sanders disk plow.

Standard Tractor Co.—22-24, gasoline, drawing 6-gang P. & O. disk plow.

Western Tractor Co., Dallas—8-15, gasoline, drawing 3-gang P. & O. disk plow.

ACCESSORY EXHIBITORS

Avisco Oil Co., L. Sonneborne & Sons, McQuay-Norris Mfg. Co., Pyrene Mfg. Co. of Texas, Gulf Refining Co, Eisemann Magneto Co., Hyatt Roller Bearing Co., Domestic Engineering Co., Sumter Electric Co., Kingston Electric Co., Byrne-Kingston Co.

Tractor Ratings Committee Appointed

WICHITA, KAN., July 23—The National Gas Engine Assn. has appointed a tractor ratings committee which will seek to standardize methods of rating farm tractors, both as to drawbar pull and belt horsepower. The drawbar rating favored is in pounds pull with the time element incorporated. The belt power will be in terms of horsepower. The committee will endeavor to evolve a method which will be satisfactory to all manufacturers.

Chairman of the committee is Raymond Olney, editor, *Gas Power*. Other members are: Fred Glover, vice-president, Emerson-Brantingham Implement Co.; C. M. Eason, Hyatt Roller Bearing Co.; G. T. Strite, president, Strite Tractor Co., and H. C. Buffington, chief engineer, Minneapolis Steel & Machinery Co.

Oakland Plans Big Expansion

New Buildings To Be Completed and Machinery Installed Oct. 1

PONTIAC, MICH., July 20—Announcement is made by the Oakland Motor Co., this city, that its plans for greatly expanding its plant have been officially approved by President W. C. Durant of the General Motors Co., and building operations will begin as soon as the buildings on the old Studebaker site have been removed.

In addition to the 4-acre site, formerly a part of the old Studebaker works, negotiations have just been completed for the annexation of the solid block extending from Oakland Avenue to Howard Street, fronting on Baldwin. The new buildings will be occupied by a machine shop and additional assembly departments.

Immediate expansion of the plant was imperative in order to bring the output up to a point which will meet the demand for Oakland cars.

Until the architects have completed detailed plans, it is impossible to accurately estimate the increase in floor-space the expansion gives, but it is said that the output will be materially increased and that it will ultimately employ double the present force of workmen. Work on the new buildings will be pushed to the limit, the contracts for the work calling for completion by Oct. 1, ready for the installation of machinery already purchased and en route.

At the close of business July 1, the Oakland company was several thousand cars ahead of the last fiscal year.

Detroiter Adds $1,098 Roadster

DETROIT, MICH., July 25—The Detroiter Motor Car Co., Detroit, which heretofore has manufactured a touring car only, now has added a roadster body to fit the same six-cylinder chassis, and priced at $1,098. The new roadster body adheres to strictly modern lines, with sloping hood and cowl, slanting windshield, and sloping rear deck. There is room for three passengers in the wide seat, and at the rear there is a large waterproof compartment for luggage or other articles. The new roadster is sold with option of colors, and is upholstered in leather to match.

Many Changes in New York Overland Organization

NEW YORK CITY, July 25—The Willys-Overland Co. as a result of taking over its own branch in this city and surrounding territory, has made many changes in its local organization.

E. M. Lied, formerly zone manager in this territory, has been appointed assistant manager of the local branch in the Circle Building, on Broadway and Fifty-ninth Street. H. F. Harris, formerly assistant manager of the L. Michael Co., Chicago, Ill., becomes comptroller.

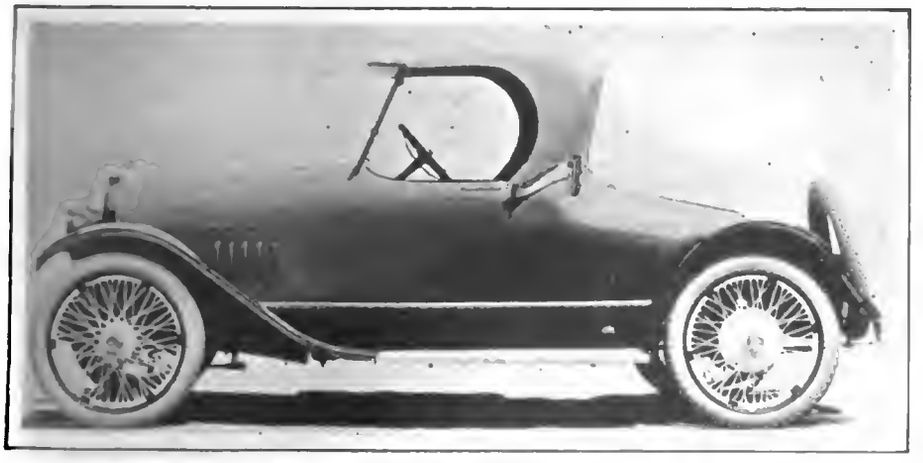
R. D. Willard, formerly manager of the Carl H. Page Co.'s branch in Philadelphia, has been appointed sales manager. S. D. Miller, also a member of the Carl H. Page Co., having managed the Brooklyn branch, joins the Overland forces as manager of the Newark, N. J. branch.

L. F. Seeback, formerly manager of the Brooklyn branch of the C. T. Silver Co., remains in that city as manager of the new Willys-Overland branch.

The Brooklyn branch is temporarily located at 338 Flatbush Avenue while the Newark branch is at 35-37 Halsey Street. The company expects to enlarge its territory by establishing branches in Yonkers and other nearby cities.

Fisher Body to Expand

DETROIT, MICH., July 22—To care for further expansion, the Fisher Body Co., body manufacturer, is preparing to float an issue of $5,000,000 of preferred stock through Hallgarten & Co., New York bankers.



New Detroiter 6-45 roadster which sells for $1,098, with complete equipment

Ford Co. Adds 34 Branches

New Quarters Planned in 28 Cities—Factory Closed for Inventory

DETROIT, MICH., July 20—The Ford Motor Co. marks an expansion of its branch sales and service organizations by the addition of thirty-four new branches, effective Aug. 1.

The cities selected for the Ford establishments are: Akron, Ohio; Albany, N. Y.; Troy, N. Y.; Baltimore, Md.; Birmingham, Ala.; Des Moines, Iowa; Duluth, Minn.; Fresno, Cal.; Grand Rapids, Mich.; Havana, Cuba; New Orleans, La.; Oakland, Cal.; Peoria, Ill.; Richmond, Va.; Rochester, N. Y.; Sacramento, Cal.; St. Joseph, Mo.; Salt Lake City, Utah; San Antonio, Tex.; Scranton, Pa.; Sioux City, Iowa; Spokane, Wash.; Springfield, Mass.; Tacoma, Wash.; Toledo, Ohio; Trenton, N. J.; Worcester, Mass., and Youngstown, Ohio.

With the establishment of these new branches the total number reaches eighty-five, besides the twenty-eight branch factories.

DETROIT, MICH., July 20—Notices are being given out to the workmen of the Ford Motor Co. whereby most of the 30,000 employed in the Detroit factories will not be required to be at work from July 25 to Aug. 7, during which period a complete inventory of property valued at approximately $100,000,000 will be taken. Ford's fiscal year ends July 31.

Two New Buildings for Monroe Body—Capital Increased

PONTIAC, MICH., July 20—Work is about to begin on two new buildings for the Monroe Body Co., an office building and a pressed steel plant. The office building is to be located on the west side of Osmun Street, and will be a brick structure 28 by 56 ft., and one story high. The new factory building will be located in the rear of the office building, fronting on the Michigan Air Line tracks a distance of 156 ft. The greatest depth will be 82 ft.

The capital stock of the Monroe company has been increased to $150,000.

Golde Top to Enlarge

NEW YORK CITY, July 25—The Golde Patent Mfg. Co., this city, will rent additional factory space in order to double its manufacturing facilities during the coming year. Besides the premises which it now occupies at 509-515 West Fifty-sixth Street, it has rented about 10,000 sq. ft. in an adjoining building 512-515 West Fifty-seventh Street. During the last 18 months this company has turned out over 89,000 one-man tops.

Comparative Statement of Packard Motor Car Co. Covering the Period from 1909 to 1917

(1) 9 months actual; 3 months estimated. (2) After writing down rights, privileges, etc., from $3,274,958.89 to $1; (3) After deducting depreciation for these 7 years of over $9,000,000.

Packard in 7 Years Earns $18,636,506

Over $9,000,000 Charged Off for Depreciation—$6,050,000 Expected During Fiscal Year.

DETROIT, MICH., July 23—In a comparative statement of its capitalization, net worth, dividends and surplus for the 7 years beginning Sept. 1, 1909 and ending at the close of the current fiscal year on Aug. 31, 1916, the Packard Motor Car Co. shows aggregate earnings of $18,636,506 after deducting more than $9,000,000 for depreciation during this 7-year period. The earnings for the present fiscal year, 9 months of which are based on actual figures and the last 3 months estimated, amount to $6,050,000 as compared with $2,769,518 for the year 1914 to 1915, which was the best previous earnings for the company. In offering this statement, F. R. Robinson, comptroller of the company, points out that the figures for the fiscal year—1915 to 1916—contain a conservative estimate covering the last quarter of the year and after paying regular preferred and common cash dividend and deducting the 10 per cent common stock dividend declared Feb. 1, 1916, and the 50 per cent common stock dividend to be distributed Aug. 1, the balance in the surplus account the end of the year will undoubtedly exceed $6,376,344. In the 7 years the capital stock of the company has been increased from $5,000,000 common and $5,000,000 preferred to $11,656,930, common stock and $8,000,000 preferred. In the same period the net assets have increased from $10,766,847 to $26,003,274.

The comparative statement by fiscal years appears herewith:

Crude Oil Prices Drop

NEW YORK CITY, July 26—The most important event in last week's market report was the drop of 10 cents a barrel of Kansas crude petroleum. Announcement was made yesterday by the Prairie Oil and Gas Co., Tulsa, Okla., that it had reduced the price to $1.45 a barrel.

Supplementing the drop in crude petroleum comes the announcement of a reduction in price of linseed and lard oils. The former product is selling now at 69 cents a gallon, and the latter at $1.05.

Rubber prices were unsteady at the closing on Saturday. Prices on fine up-river Para, however, managed to remain unchanged at 66 cents a pound. Ceylon, first latex grade, suffered a drop of 2 cents a pound, the quoting yesterday being 56 cents.

Metal prices remained constant and strong with a heavy demand.

Daily Market Reports for the Past Week

$1,275,000 Profit for Stewart-Warner

Earnings Based on 6 Months' Operations — Declares Quarterly Dividend of 1½ Per Cent.

CHICAGO, ILL., July 20—The Stewart-Warner Speedometer Co. has declared the regular quarterly dividend of 1½ per cent on the common stock, payable Aug. 1 to stock of record July 22.

The corporation reports for the 6 months ending June 30 last net profits of $1,275,000, a new high record. The net profits in the last quarter totaled $703,254, against $571,873 in the first quarter of the calendar year.

The balance sheet shows assets as follows: Real estate, buildings, machinery, etc., less depreciation, $1,720,774; patents, trade marks, and good will, $9,096,967; inventories and receivables, $3,454,008; deferred charges $154,158; total assets, $14,425,908.

Liabilities: Preferred stock $724,400; common stock $10,000,000; current liabilities $420,317; surplus $3,281,191. Surplus includes $307,463 set aside to retire the preferred stock.

Sewell Cushion Increases 300 Per Cent

DETROIT, MICH., July 20—The Sewell Cushion Wheel Co., this city, shows an increase in business for the first quarter of its fiscal year of 300 per cent over the same period last year.

Plans are now being formulated for establishing service stations, in connection with the branches in Buffalo, Boston, New York City, Philadelphia, Baltimore, Minneapolis, Rochester, Cleveland, St. Louis, Pittsburgh, Los Angeles, Seattle, and Chicago. A service station is maintained at the factory for the benefit of Detroit users.

Murray Parts Increases Capital

DETROIT, MICH., July 25—The J. W. Murray Mfg. Co., this city, maker of au-

tomobile parts, has increased its capital from $200,000 to $500,000. $250,000 of this amount is subscribed, the greater portion of which will be paid in by the declaration of a 100 per cent stock dividend, the balance being taken by the directors.

To take care of its increased business, the company has also recently invested in 3½ acres of additional property and a factory, at an outlay of $175,000. This will serve to double its capacity, as all the original plants will still continue to be operated, and will afford in all over 150,000 sq. ft. of floorspace.

—

Burdick and Hagerman Now Control Central Wheel

STURGIS, MICH., July 20—A deal was consummated to-day whereby F. L. Burdick and Roy H. Hagerman have purchased the controlling interest in the Central Wheel & Mfg. Co. The purchase was made from Mrs. Emma Westendorf, formerly vice-president. The company was organized in 1909, and its products include wheels of all sorts.

—

Wichita Falls Plans to Expand

WICHITA FALLS, TEX., July 24—The Wichita Falls Motor Co. has increased its capital stock from $100,000 to $400,000. It has met with much success in manufacturing motor trucks at its plant here and it is stated that it plans to greatly enlarge the industry.

Securities in Demand

—

Chevrolet and Maxwell Feature Rise in Prices—Stocks Are Strong

NEW YORK CITY, July 26—Automobile securities showed pronounced strength last week and picked up somewhat in prices. Rumors of further mergers and dividend action had their potent effect on the market in general and prices rose as a result of the demand in those stocks so affected. The market as a whole was steadier than last week and stocks were in demand.

Chevrolet and Maxwell featured the market with rises of 22 points and 7⅜ points, respectively. Dame Rumor has it that Chevrolet common is due for a large dividend and as a result it is expected that the stock will reach a new high mark before the next month is over. Maxwell rose as a result of the belief that the directors of that company will place the common stock on a dividend basis at their meeting on Aug. 8. This stock was one of the most active of the motor stocks, the turnover on Saturday being 5400 shares. It is expected that if the common stock dividend is declared that the second preferred will come in for an initial dividend.

The new Stromberg and Kelsey Wheel stock was introduced on the Curb last week. The former sold at $42, $42.25 and $42.50, the sales amounting to 1800 shares. Kelsey Wheel common advanced from 60 to 63 after its introduction. Stewart-Warner Speedometer common, it is stated, will be listed on the New York and Chicago stock exchanges.

Stutz stock was one of the strongest issues on the curb Saturday due to rumors of a merger of that company with Stromberg. Both of these companies are now under control of Allan A. Ryan & Co., this city.

—

Wayne Oil Increases Capital $200,000

FORT WAYNE, IND., July 25—The Wayne Oil Tank & Pump Co., this city, has increased its capital from $500,000 to $700,000. The object of the increase is to provide for big additions to the plant to take care of the concern's rapidly expanding business. Among the improvements will be the construction of a factory building nearly 400 ft. long.

—

Reports $13,000 in Krit Assets

DETROIT, MICH., July 22—Final reports in the case of the Krit Motor Sales Co., the bankrupt selling organization for Krit cars, were filed in the United States district court here this week, and show approximately $13,000 of the company's assets remaining on hand. The total receipts for the sale of the property were $81,126 and the total disbursements $67,883, of the latter $65,047 representing dividends to creditors amounting to 37½ per cent. Indications are that another dividend of about 4 per cent will be declared.

Plan Another Desert Race

Course from Los Angeles to Salt Lake Over Arrowhead Trail

SAN BERNARDINO, CAL., July 19—There is to be a desert road race staged in the Southwest this fall which will not be a revival of the Phoenix road race. There is to be a race from Los Angeles to Salt Lake over the Arrowhead Trail, a road that cuts in on the National Old Trails route between this city and Needles.

Charles Biglow, field secretary of the Arrowhead Trail Assn., which is promoting the event, was in Los Angeles yesterday for a conference with Al. G. Waddell, representative of the contest board of the A. A. A. and a car is going out to pathfind the route within the next few days. The dates asked for by the Arrowhead Trail Assn. are Oct. 8, 9 and 10. The race is to finish at Salt Lake at at noon of the third day, Oct. 10, which is the opening day of the Mormon Conference. One night control is to be at Ely, Nev., and the second is to be at St. George, Utah.

From St. George into Salt Lake, the cars are to be limited to a safe pace on account of the great number of children in the country through which the Utah State highway passes.

It is planned to have a large enough purse to offer $5,000 first money. The Salt Lake Railroad is to run the "Howdy Special," which was always a feature of the Phoenix races.

—

Eleven Perfect Scores in Truck Reliability Run

EXPOSITION GROUNDS, SAN DIEGO, CAL., July 20—Eleven out of fourteen trucks entered in the commercial vehicle reliability run of 150 miles from San Diego to Los Angeles on July 15, finished with perfect scores. The run was over the worst highways of southern California.

The trucks ranged from 1000 to 12,000 lb. capacity. Those that were penalized had minor troubles.

The following list gives the truck, the name of the driver and the load carried:

Truck and Driver.	Load Carried
Vim, Krapp	1,100
Vim, Kirkpatrick	1,100
Vim, Lloyd	1,200
Downe, Miller	12,000
Stewart, Fouch	1,030
Studebaker, Futley	1,090
Studebaker, Fortine	2,121
Smith Form A Truck, Meisel	2,090
G. M. C., Hurd	7,400
Denby, H. G. Pendell	3,010
Little Giant, Darin	1,590
Little Giant, Johnson	3,130
Autocar, Heffner	3,150
G. M. C., Burris	1,670

Another truck reliability tour is planned. The Motor Truck Dealers' Assn. of Los Angeles has made application to the Contest Board of the A. A. A. for a sanction for a run Oct. 22 and 23. This run would be approximately 400 miles and the course would include every road condition.

—

Accidents Mar Tacoma Races

TACOMA, WASH., July 23—*Special Telegram*—Ulysses Aubrey, driving a Tacoma special and his mechanician, Frank Lake, were instantly killed in the Australian pursuit race on the Rose City Speedway to-day. A series of accidents marred a good race program with record attendance. F. M. Penticost, driving the Schnieder Special, went through the fence but was unhurt. M. J. Moosie of Los Angeles, in the Gandy special, plunged 300 yd. and his car jumped 22 ft. in the air with a broken steering knuckle. The 50-mile race was won by Omar Toft of Los Angeles, time 49 min. 27 2/5 sec. The 20-mile race also was won by Toft in 20 min., 29 1/5 sec.

—

Sealand Resigns from Winton

DETROIT, MICH., July 21—F. A. Sealand, manager of the Detroit branch of the Winton Motor Car Co. for the last 4½ years, has resigned to become general manager for T. H. Towle, proprietor of the Cleveland-Cadillac Co., the Columbus-Cadillac Co., and the Toledo-Cadillac Co.

De Palma Wins at Kansas City

Takes 100-Mile Race at 58.48 M. P. H.—O'Donnell Injured in 25-Mile

Winners of 100-Mile Race

Car	Driver	Time	M.P.H.	Prize
Mercedes	DePalma.	1:42:54	58.4	$2,500
Duesenberg	O'Donnell.	1:45:6	57.02	1,000
Duesenberg.	Buzane...	1:49:42	54.6	600
Kleinart....	Klein ...	1:54:56	53.1	400

KANSAS CITY, MO., July 22—Marred by only one accident, an injury to Eddie O'Donnell, the daring Duesenberg driver, Kansas City has at last held a successful speedway meet. O'Donnell will be out of the hospital in 2 weeks.

Ten thousand enthusiastic Kansas Cityans this afternoon saw Ralph de Palma in his cream-colored Mercedes win the 100-mile grind after a thrilling contest with O'Donnell. The Italian's time was 1:42:54, or an average of 58.48 m.p.h.

After cheering O'Donnell to the echo for his game fight against the veteran De Palma, the crowd saw the clever little driver hurtle through the fence on the first turn of the track in a 25-mile event which followed the first race. He was badly hurt but his mechanician was unhurt. A broken steering knuckle caused the accident.

Before the 100-mile race had been half finished the 1⅛-mile dirt speedway became so full of ruts and wallows that it became necessary to shut off the power entirely at some places. The strain on the cars was so terrific that only five out of twelve starters finished, although there were six money prizes. The terrible condition of the course had something to do with the fact that less than half the starters finished the first race. De Palma, after winning the first event, refused to enter the second, which had been originally scheduled to go 50 miles but was cut down to 25.

De Palma drove his usual steady pace, stopping only twice at the pits, once to replace broken goggles and the second time to change a tire.

Eddie Rickenbacher's Maxwell led the field until the thirty-second lap, setting a hot pace. Up to the time he was forced to quit because of a broken water connection he had averaged 66.77 m.p.h. When Rickenbacher relinquished the lead to O'Donnell, the Duesenberg driver maintained first place until the sixty-sixth lap, when De Palma took it from him in a sharp brush in front of the grandstand.

Second Race Unfinished

A bad accident was narrowly averted because Burt stopped his Ogren car at the pit just before his rear axle, which had been cracked, became dangerous. He was third in the race at this time.

The second race never was finished, the only two contestants being left on the course after O'Donnell's accident being flagged down at the end of the fourteenth lap. W. W. Brown, driving a DeChesneau, who was leading at that time probably will be given first money, however, $600. Art Johnson who was also on the course in a Crawford probably will be awarded second prize, $400.

The speedway association plans strengthening the track and holding a meet Oct. 7, the last day of the American Royal Live Stock Show.

—

King and Winterson Join Chalmers

DETROIT, MICH., July 24—C. H. King and J. P. Winterson have been added to the sales staff of the Chalmers Motor Co. Mr. King has been connected with the automobile field since 1905, having been with such companies as the Motor Car Sales Co., New York City and the H. L. Keats Auto Co., agent for the Chalmers in 1907 at Portland, Ore. Mr. Winterson was connected several years ago as a member of the Lozier staff in New York City. Later he joined the Chandler organization.

—

Backus Ford's Baltimore Mgr.

BALTIMORE, MD., July 20—E. T. Backus has been appointed manager of the branch of the Ford Motor Co. in Baltimore, Md., which will be opened Aug. 1.

Start of the 100-mile race on the Kansas City speedway. This event was won by De Palma in his Mercedes with O'Donnell's Duesenberg second

Saxon Relay Breaks Record

43 Sixes Relay from New York to Frisco in 6 Days, 18 Hr. and 10 Min.

DETROIT, MICH., July 22—Forty-three Saxon six automobiles, racing in relays, established a new transcontinental record when the last car reached San Francisco precisely at 4.40 Saturday morning, 6 days, 18 hr. and 10 min. after leaving New York City.

This record from coast to coast was made carrying a message from Mayor Mitchel, of New York to Mayor Rolf of San Francisco, over the proposed Lincoln Highway route.

An official observer started with the first Saxon car at 10.26 a. m. Saturday, July 15, and went the entire distance by changing from car to car as the relay progressed. The cars were driven by regular Saxon dealers and while the official mileage of the Lincoln Highway is 3,331 miles, it is stated that the total distance traversed was considerably more than this, due to detours, etc. The Saxons averaged about 25 m.p.h. for the entire distance. Forty-two changes from car to car were made.

—

Rubber Interests on Outing

BOSTON, MASS., July 20—The 17th annual outing of the Rubber Club of America was held on July 17 and 18, taking in places and events of interest in both Boston and Lowell.

A large delegation of western men, headed by H. S. Firestone, president of the club, P. W. Litchfield of the Goodyear company, C. B. Raymond, secretary of the Goodrich company, and W. O. Rutherford of the Goodrich company, as chairman of the western delegation arrived here to-day.

The last day was devoted to match plays at golf, tennis, baseball, etc.

—

Minneapolis Speedway Suspended

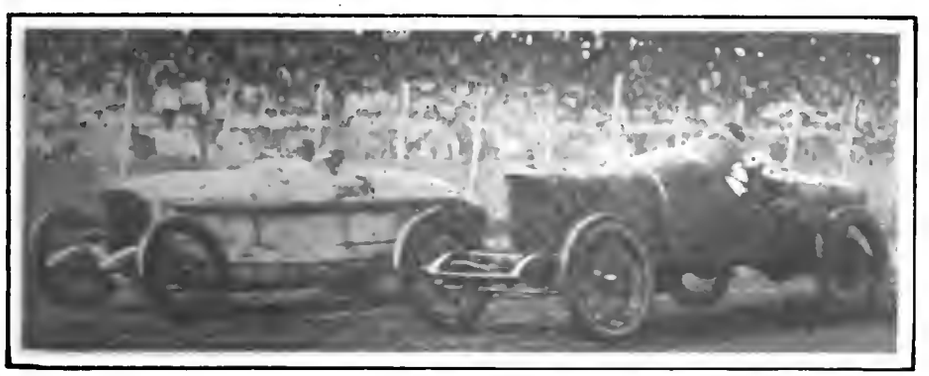
NEW YORK, July 25—The track license of the Minneapolis speedway which was opened scarcely a year ago was withdrawn by the Contest Board of the A. A. A. to-day, due to certain difficulties that arose in connection with the meet there on July 4, when the prize money was not posted and when the drivers had to take $6,800 instead of $20,000 as advertised in the entry blanks. J. F. Sperry, manager of the track has been suspended for 2 years for difficulties in connection with the meet, which was a fiasco.

Because of the small attendance at the Sioux City races on July 4, when the drivers' prizes were 50 per cent of the gate receipts and when the drivers were not adequately reimbursed for their expenses, the board voted not to grant any future sanctions where cash prizes are a percentage of gate receipts. In such cases the drivers have little chance of perhaps even paying expenses.

Indianapolis speedway has applied for a sanction on Sept. 9 for a championship 100-mile event, the prize being $900. Shorter events may also be listed.

Two competition records were allowed, both to Dario Resta in the Chicago race of June 18. The 50-mile mark allowed is 31:57 2/5 as compared with the old mark of 33:55.42. The other mark was at 10 miles, the time being 5:51 1/5, as compared with the old mark of 6:35.52.

For not advertising one of its speedway performances in accordance with A. A. A. rules the Hudson Motor Car Co., Detroit, was fined $1,000 with the option of disqualification until Jan. 1, 1917. This was in connection with races on the Chicago speedway, June 17.



De Palma taking the lead away from O'Donnell in the 100-mile race on the Kansas City speedway. The brush occurred on the grandstand stretch

Factory Miscellany

To Make Parts—The L. O. Gordon Mfg. Co., Muskegon, Mich., has been formed by a syndicate of Cleveland and Muskegon capitalists to manufacture automobile parts. The erection of a plant to cost $100,000 will begin at once.

National Rubber Buys Land—The National Rubber Co., Pottstown, Pa., has purchased additional land on which it will erect a large factory.

Allen to Add—The Allen Motor Co., Bucyrus, Ohio, has broken ground for the erection of a large addition to its motor and transmission plant.

Clyde Truck Breaks Ground—The Clyde Motor Truck Co. has secured a tract of 40 acres at Farmingdale, L. I., and plans are now about complete for the breaking of ground for the erection of its factory buildings there.

New Tire Plant for Cuyahoga Falls—A new tire plant will shortly be opened in Cuyahoga Falls, Ohio, in the old factory building recently vacated by the Falls Rubber Co., and purchased by the new company. The new concern is backed by Akron capitalists and is incorporated at $25,000 and will be known as the Supreme Rubber Co. Daniel Zeistof of that city, formerly connected with the Marathon Rubber Co., will be general manager. The building will be ready for work in about three weeks.

Firestone Factory Picnic July 29—The Firestone Tire & Rubber Co., Akron, Ohio, will hold its annual picnic on July 29 at Silver Lake Park, near Akron. It is expected that during the course of the day and evening at least 25,000 people will be in attendance.

Maxim Silencer Uses Tent—The Maxim Silencer Co., Hartford, Conn., pending the completion of a new addition to the factory is making use of a tent for the welding department. The general offices have been removed from the factory to an adjacent dwelling, which is connected with the factory by a runway. Still another addition is being considered by the company.

New Departure Adds—An addition is to be made to the factory of the New Departure Co., Bristol, Conn., 300 ft. long and U-shaped. This will be known as the ball department when it is completed. The company has acquired considerable other ground for enlargement of the factory.

New Plant for Los Angeles—The latest manufacturing concern to enter the field in southern California is the Davis Manufacturing Co., which is located at 1238-44 South Flower Street, Los Angeles, Cal. The concern is manufacturing complete the Standard truck attachment and doing general machine work, making parts for any automobile or truck on the market.

Takes Over Top Co.—Continental Auto Top Mfg. Co., St. Louis, has taken over the plant and business of the Continental Auto Top Co. Arthur Leeser succeeds G. I. Juhlein as owner of the majority interest. The plant at 814-16-18 is being entirely overhauled. Automobile tops, jiffy curtains, seat coverings and commercial bodies are the output.

Miller Rubber Holds Outing—The thousands of employees of the Miller Rubber Co., Akron, Ohio, held their annual outing and picnic at Silver Lake, July 15. It was planned to hold the outing at Cedar Point, but inability of railroad companies to furnish equipment made it necessary to hold it nearer home. The day was spent in games and athletic events.

C. A. S. Products Busy—The new plant of the C. A. S. Products Co., Columbus, Ohio, recently formed with a capital of $100,000 to manufacture the Foster gear, an invention of a Columbus man, has booked orders to keep the plant to capacity until June, 1917. C. D. Cutting of Detroit is president and general manager, and A. W. Tyler is secretary and superintendent. The plant has 50,000 sq. ft. of floor space and already additions and extensions have been started. More than 150 men are on the pay rolls.

Leak-Proof Plant Expanded—The McQuay-Norris Mfg. Co., St. Louis, has just completed an addition to its factory which increases the plant by one-third and gives 100 ft. of frontage on Locust Street in the heart of the automobile district.

The AUTOMOBILE

VOL. XXXV NEW YORK—THURSDAY, AUGUST 3, 1916—CHICAGO No. 5

G. M. C.—121,113 Cars in 11 Months

Earns $144,000,000 or $50,000,000 More than in All 1915

	1916	1915
Earnings, 11 months	$144,000,000	$86,000,000
Automobiles, 11 mos.	121,113	68,604

DETROIT, MICH., Aug. 1—Gross sales of the General Motors Co. for the first 11 months of its fiscal year, or to June 30, were $144,000,000. This is over $58,000,000 more than the sales for the same 11 months of the 1915 fiscal year. This total of gross sales is nearly $50,000,000 more than the total sales for the entire fiscal year of 1915.

In the 11 months ending June 30 there were 121,113 automobiles produced by the organization as compared with 68,604 in the corresponding months of the previous year. In the first 11 months of this year the company has produced 43,045 cars more than in all of 1915.

President W. C. Durant states that the undivided profits applicable to common stock amounted to approximately $24,500,000 on June 30 this year instead of $11,686,280 for the similar period of 1915. On June 30 General Motors had approximately $25,700,000 in cash in banks and in sight drafts with documents attached. July is expected to show very satisfactory results, although in some of the plants of the company there might have been a slight decrease in production on account of inventories

Friend Is United Motors V.-P.

RACINE, WIS., Aug. 1—Otis C. Friend has resigned as sales manager of the Mitchell-Lewis Motor Co. to become vice-president and general manager of the United Motors Co. He commences his new duties in the New York City offices of the United Motors Co. the middle of August. Mr. Friend has been connected with the automobile industry for nearly a score of years, beginning with the Chicago sales of the Locomobile. He joined the sales force of the Chicago Mitchell agency in 1900, and later handled Mitchells as the firm of Brown & Friend in Milwaukee.

Mr. Friend then became purchasing agent of the Mitchell-Lewis factory here and was successively assistant to J. W. Bate and general superintendent of shops. Later he became assistant factory manager, assistant sales manager and advertising manager. His successor at the Mitchell factory has not yet been appointed.

—

Coffin Goes to Europe

NEW YORK CITY, Aug. 2—Howard E. Coffin, consulting engineer of the Hudson Motor Car Co., sails for Europe next week on the Philadelphia to spend a month in England and France investigating industrial and transportation conditions in these countries. Mr. Coffin is a member of the U. S. Naval Consulting Board and has taken a very active interest in motor transport as connected with the government during the present year.

—

Dort Raises Price to $695

FLINT, MICH., Aug. 2—The Dort Motor Car Co., this city, has raised the price of its touring car from $665 to $695, beginning Aug. 1.

—

Stewart Warner Buys V-Ray

CHICAGO, ILL., July 31—The Stewart-Warner Speedometer Corp. has purchased the V-Ray Spark Plug Co., of Marshalltown, Iowa, and will begin the manufacture of V-Ray plugs in the new addition to the Chicago plant of the Stewart company. Production will be increased to several thousand a day. V. S. Hanson, president of the V-Ray company, becomes manager of the spark plug department.

Ford Prices Cut 18 Per Cent

Touring Model Now Sells for $360—Roadster Reduced to $345

PRESENT AND FORMER PRICES OF FORD CARS

	Aug. 1 1916	Aug. 1 1915	Aug. 1 1914	Aug. 1 1913	Aug. 1 1912
Touring	$360	$440	$490	$550	$600
Roadster	345	390	440	500	525
Chassis	325	360	Not sold	Not sold	Not sold
Coupelet	505	590	750	....	....
Town Car	595	640	690	740	....
Sedan	640	740	975	....	....

DETROIT, MICH., July 31—Starting with Aug. 1 new prices on Ford cars will prevail. The reductions vary all the way from $35 on the chassis up to $95 on the sedan. The touring car has been reduced $80 from $440 to $360. The runabout is now $345 instead of $390. The chassis alone sells for $325, whereas it formerly sold for $360. The coupelet is $505 instead of $590, the town car $595 instead of $640 and the sedan $645, which is a $95 reduction from the former price of $740.

Improved Body Lines

Accompanying the change of price there will also be a change of appearance, as the new Ford cars will be fitted with sloping hoods and crowned fenders which will give a new outline. The radiator shape also will be remodeled to accord with the molded form that has now been adopted.

From time to time Ford prices have been reduced materially and it is outside rumor that the eventual aim is a $250 car with a production schedule of 1,000,000 cars per annum. Recent property acquisitions will more than double the available factory space, and since the schedule is now 500,000 cars a year, it does not seem impossible that the 1,000,000 mark will be reached. Ford reached a production of 1000 cars a day during

Studebaker Earns $6,028,329

Only $180,000 Profit from War Orders—Common on 10% Basis

SOUTH BEND, IND., Aug. 2—At the regular meeting of the directors of the Studebaker Corp. yesterday the regular quarterly dividends of 1¾ per cent on the preferred stock were declared and the common stock was put on a regular 10 per cent basis by the declaration of 2½ per cent quarterly dividends, which, like the preferred dividend, are payable Sept. 1. Heretofore the common has received quarterly dividends of 1½ per cent plus 1 per cent extra.

Net profits for the 6 months ending June 30, after deductions for appreciation and profit sharing, were $6,028,329.16, including $180,000 from war order profits. After deducting the 7 per cent dividends on the preferred stock, this figure is 18.8 on the common stock outstanding and is at the rate of 37.6 per cent for the year.

During the corresponding period of 1915 the corporation's net profit amounted to $5,774,074.87, which included nearly $3,000,000 of war order profits, while this year's profits include only $180,000 from war order profits. Thus the profit earned from regular business this year was $5,848,329.16, as compared with $2,774,074.87. The increase this year was thus 11 per cent. On June 30 the total surplus in reserves amounted to $16,664,160.69. Cash on hand exceeds $4,000,000 and the corporation is wholly free from indebtedness.

War order contracts are about completed and the corporation is not seeking new business of this character. The plants have been operated at full capacity on regular business for the past 12 months and are earning 80 per cent ahead of last year in the automobile division and 50 per cent in the horse-drawn vehicle division. The domestic business in a general way is 50 per cent greater than at any previous time of the corporation's history.

—

Ver Linden Is Oldsmobile Manager

LANSING, MICH., July 31—E. Ver Linden, factory manager and associate executive of the Olds Motor Works, this city, has been created general manager following the resignation last week of Jay Hall. Committee management at the works is now abolished in favor of one-man control. It is expected to increase the output next year to over 20,000 cars.

Before joining the Olds organization, Ver Linden was production expert for the Buick company, managing plant No. 1. Before that he was in business for himself, under the corporate title of the Michigan Auto Parts Co., which was bought out by the General Motors Co. in 1909. His early training in production methods was gained with the American Radiator Co.

—

Goodrich Profits for 6 Months $4,800,000

AKRON, OHIO, July 29—The books of the B. F. Goodrich Co., this city, were closed on July 1 for the purpose of determining the result of operations for the first 6 months of 1916. After making proper provision for maintenance charges, depreciation, doubtful accounts and all known outstanding current liabilities; the net profits for the period amounted to $4,800,000, an increase of 20 per cent from the same period a year ago, net then being $4,000,000. The increase alone is equal to the 6 months' dividend on the $27,000,000 preferred.

—

Nash Motors Co. Incorporated with $24,999,500 Capital

BALTIMORE, MD., July 29—The Nash Motors Co., which has been organized to take over the Thomas B. Jeffery Co., Kenosha, Wis., as reported in THE AUTOMOBILE for July 20, applied for incorporation before the state tax commissioner here this afternoon, with a capital stock of $24,999,500. R. F. Herrick, J. Wells Farley, Edward A. Taft and Phillips D. Ketchum, all of Boston, are named as incorporators.

Marmon Coast-to-Coast Record

S. B. Stevens Covers Distance in 5 Days, 18 Hr. and 30 Min.

SAN FRANCISCO, CAL., July 29—A Marmon car driven by S. B. Stevens, well known in motoring circles around New York, reached San Francisco to-day, having crossed the continent in the record time of 5 days, 18 hr. and 30 min. This is a gain of more than 41 hr. over the record established by the Cadillac eight last May.

The car left Columbus Circle, New York City, at 1.30 a. m. July 24, and on its trip covered a distance of 3476 miles at an average speed of 25.1 m.p.h. The record made by Baker in the Cadillac was established at an average of 18.8 m.p.h. The car traveled as far as Cheyenne at an average of better than 32 m.p.h., but owing to bad roads beyond that point its average was pulled down to nearly 25.

(*Continued on page* 206)

Maxwell to Pay 10% on Common

Committee Also Will Recommend Dividends on Preferred —Earnings Over $5,000,000

NEW YORK CITY, Aug. 2—The executive committee of the Maxwell Motors Co. has decided to recommend to the directors payment in full of the outstanding dividend warrants on the first preferred stock, payment of quarterly dividends on the second preferred at the rate of 6 per cent per year, beginning Oct. 2, and the inauguration of quarterly dividends on the common stock at the rate of 10 per cent per year, also beginning Oct. 2. More than 90 per cent of the first preferred dividend warrants have been converted into first preferred stock.

The earnings of the company for the fiscal year ending July 31 will be in excess of $5,000,000.

—

Signal-Commerce Merger Completed

DETROIT, MICH., Aug. 1—The merger of the Signal Motor Truck Co. and the Commerce Motor Car Co. to form the Signal-Commerce Motor Truck Co. has been completed. An issue of 450,000 shares of stock will include 250,000 shares to be offered to the public at $6 per share, the remainder of the stock going to the owners of the two companies. Thomas Neal, former president of the General Motors Co., is president of the new concern and Walter Parker is vice-president. Other officers will be announced later.

—

International Motor Plans Exchange

NEW YORK CITY, Aug. 2—It is understood that the International Motor Co.'s financial readjustment, which is being worked out in view of the approaching maturity of $2,800,000 of notes on Nov. 1, will propose an exchange of new first preferred stock with a bonus of 50 per cent in new common stock for the notes.

—

Adams Trucks No More

FINDLAY, OHIO, July 29—The Adams Truck, Foundry & Machine Co., of this city, which 2 years ago changed its name to the above from that of the Adams Bros. Co., has discontinued the manufacture of Adams commercial vehicles, to concentrate on foundry and machine shop work.

—

Prescott a Stutz Director

NEW YORK CITY, July 29—Sherburne Prescott has been elected a director of the Stutz Motor Corp., succeeding K. R. Howard.

Exports Total $97,464,381

Year Ended June 30 Shows Falling Off in Last Month Despite Huge Total

WASHINGTON, D. C., July 29—The exports of automobiles during the fiscal year ended June 30, 1916, reached a total of 77,496 machines, valued at $97,464,381, together with parts, not including engines and tires, to the value of $22,536,485, according to figures compiled by the Department of Commerce. During the fiscal year the exports were classified as follows: Commercial cars, 21,265, valued at $56,805,548; passenger cars, 56,231, valued at $40,658,833. During the fiscal year of 1915 there were 37,876 machines exported, the value being $60,254,635, the exports consisting of 13,996 commercial cars, valued at $39,140,682, and 23,880 passenger cars, valued at $21,113,953.

While the year's totals mounted high the figures show a decided falling off during June last as compared with the same month of last year. During June last 1416 commercial cars, valued at $3,551,148; and 4905 passenger cars, valued at $3,416,396 were shipped abroad, together with parts, not including engines and tires, to the value of $1,886,746. In June a year ago the exports consisted of 2990 commercial cars, valued at $8,578,802, and 4418 passenger cars, valued at $4,785,998.

Manufacturers interested in the export trade will find much to interest them in the accompanying table, which shows the number and value of vehicles, both commercial and passenger, shipped to various foreign countries during June last.

Canada was the largest customer for passenger cars, taking 1145, with British South Africa second with 553 and France third with 408. Among the South American countries, Argentina made the best showing, taking 369, while Venezuela bought ninety-one, Chile seventy and Brazil forty-seven.

Weatherproof Body Reorganized—Takes Over Wilson

DETROIT, MICH., July 31—The Detroit Weatherproof Body Co., which was organized during the latter part of 1915, has been reorganized, having taken over the business of the C. R. Wilson Body Co. The company's capital stock is now $750,000, instead of $10,000 when it was first incorporated. The concern manufactures the Detroit top, which is a detachable, convertible, all-year-around limousine top of medium price.

The Weatherproof company has secured factory space totaling about 50,000 sq. ft. at 1884 Mount Elliott Avenue and will employ several hundred men. A new factory will be erected some time during the latter part of the year. It is planned to make from 50,000 to 100,000 tops. The officers of the company are: S. P. Douglass, president; Lawrence Moore, vice-president and general manager; H. H. Sanger, treasurer, and H. B. Barbour, secretary.

Tractors Make Hit in Kansas

Demonstration Shows Ability of Machines to Plow in Sun-Baked Soil

By S. P. McMinn
Staff Correspondent.

HUTCHINSON, KAN., July 27—Kansas soil is proving a difficult test for the farm tractors that have been brought here for the second of the series of eight national tractor demonstrations started July 18 in Dallas, Tex. The Kansas demonstration was officially opened on Tuesday and from then until now the grounds have been thronged. The attendance is, perhaps, not quite as good as it was at Dallas because there is not as great a metropolitan area from which to draw and because railroad facilities are not as good. Still, the crowd is an excellent one and has been drawn from the farthermost corners of the State.

A fair number of bona fide sales already have been made, though few dealer and distributor contracts have been signed to date. Manufacturers are now signing prospects obtained at the Dallas demonstration, many of them having left men behind for the purpose, so it is likely much of the business here will be deferred until after the furore of the demonstration has subsided somewhat. In a measure this is an encour-

South America—II

Argentine Growing Market for U.S.A. Cars—Needs Population—Rich But Backward in Development—Accommodations Excellent—Industries Progressing

Part II

By David Beecroft

LAST week was told the past and present of the automobile industry in the Argentine and how the lower-priced American cars started selling nearly 2 years ago in the agricultural sections and a year ago took a perceptible jump forward in volume of sales. This week we take a closer look at this country, having in mind its possible purchasing capacity for automobiles.

The Argentine republic, with its population of 8,000,000, must not be looked upon as a new country for its oldest cities were founded between 1515 and 1535 so that, measured in years, they are older than New York City. Argentina boasts of its national university at Cordoba, a night's ride by train west from Buenos Aires, because it is many years older than Harvard and perhaps the oldest university in the western world. To-day it has a very high standard and while not the largest institution of the kind is still a potent educational force. So through the country you find evidences of antiquity on every hand.

Population Too Small

Yet Argentina is an undeveloped land compared with the United States. She has great areas but not enough population. Population is her greatest need. Nature has been kind to her, but industrial progress has been kinder during the past century to North America than to South America. North America is a week from Europe and the old world but South America is 3 weeks off. This remoteness has had its influence.

But other differences have been at work. North America has grown up under the influence of Anglo-Saxons and Teutons, whereas South America, with the exception of Brazil and Guiana, was reared under the Spanish régime. South American republics threw off the Spanish yoke during the Napoleonic wars 100 years ago. In fact, it was just 100 years ago in July that Argentina finally got its constitution ratified. But the development of Argentina under its own government was slow and it was really not until 1852 when progress started and it is only in the last 35 years that rapid development has taken place. The great meat exporting industry is 35 years old and other industries have sprung up since that date.

To-day the country is making rapid progress, year by year old influences are being thrown aside and more modern measures adopted, but still you must not think of Argentina in

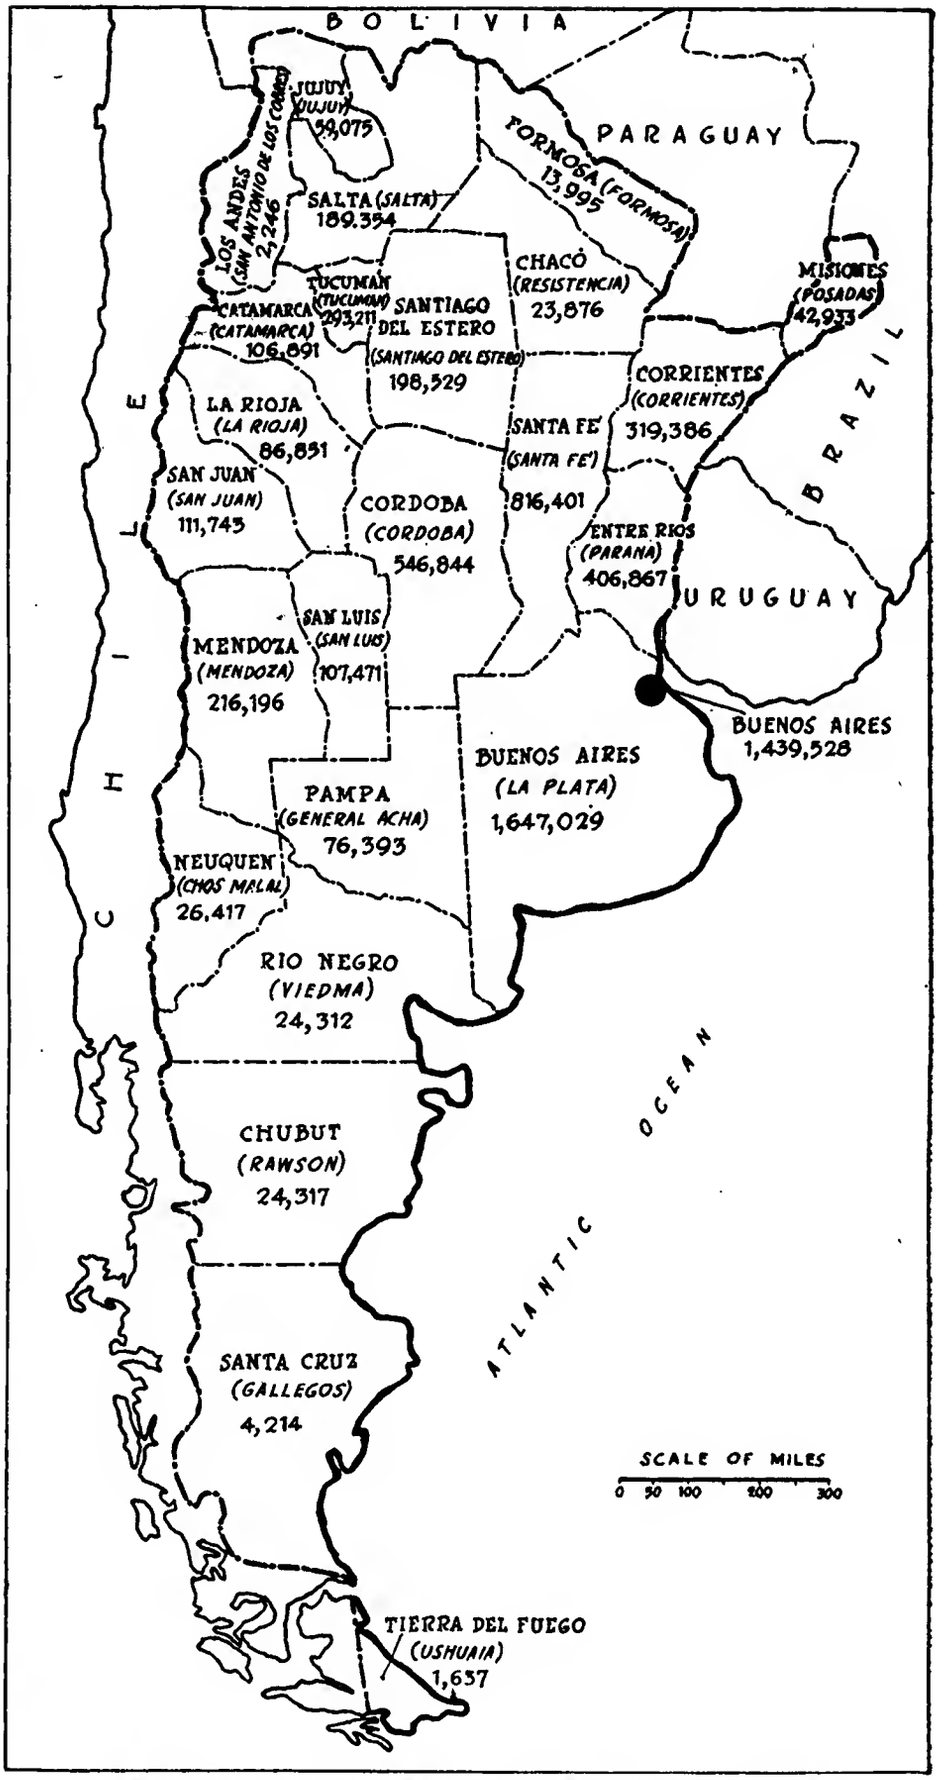
One street in Buenos Aires which is largely used for automobile salesrooms. The J. I. Case Co. occupies the corner

the same way you think of the United States. You must think of it as a land with 8,000,000 people, one-half of whom are Argentines and the other half foreigners. You must think of Argentina as a land very rich in Agricultural possibilities, but laboring under an agricultural system in which land is held in huge areas of 100,000 acres or more and where the small farmer as we know him does not exist. You must not think of it as a land like Iowa, dotted with comfortable small homes located on farms of 160 or 320 acres in extent, but rather as a land dotted with mud huts which our farmers would refuse to live in. Sparsely situated from 10 to 20 miles apart are the city-like homes of the large landowners. This system of farming gives a low percentage of potential buyers as compared with our system of small farms where the majority hold title to their property.

A Wide Expanse

Argentina is not generally settled throughout its length and width as is the United States. There is not enough population. Spread 8,000,000 over the United States east of the Mississippi and you will get some conception of how sparse the population really is. The north central part of the country from Buenos Aires west to the Andes and south for several hundred miles is the most thickly settled. The southern half of the country is very thinly populated, being used partly for sheep grazing and cattle, and there is not any agriculture. The northern section is largely timber lands. That part around the City of Buenos Aires and north is well watered, there being an ample rainfall, in fact too much at times. Going west toward the mountains the rainfall diminishes and irrigation is needed the same as in our western States. In the great grape growing area the rainfall is but 8 in. per year as compared with 37 in. along the river Plate, as the Rio de la Plata is called.

Perhaps the best conception of how Argentina is populated can be had from a brief glance at the divisions of the republic. Argentina is divided into twenty-five divisions, fourteen of them being called provinces and ten territories, the last one being the federal capital and corresponding to our District of Columbia. Buenos Aires is located in the federal capital area. The City of Buenos Aires has nearly 25 per cent of the entire population of the country. In four provinces are located 72 per cent of the total 8,000,000. Imagine 72 per cent of the population of the United States being grouped into New York, Connecticut,



ARGENTINE REPUBLIC, SHOWING DIVISION INTO PROVINCES

Tha Argentine Republic is divided into twenty-five political divisions, fourteen of which are provinces corresponding to different states in U. S. A. Ten ara territories which have not yet attained tha political statura of states, and one is a federal district in which the city of Buenos Aires is located, and corresponds to the District of Columbia in U. S. A.

Middle—Studebaker salesroom in city of Rosario, which is a six-hour railroad ride from Buenos Aires

Bottom—Overland salesroom in Rosario. This salesroom is typical of many seen in this city as well as in similar cities in the Argentine

New Jersey and Pennsylvania or similar small areas.

The four provinces that contain 72 per cent of the population are Buenos Aires, which contains the city; Santa Fe, Cordoba and Entre Rios, all bordering on the province of Buenos Aires on the west and north. The map shows these, as well as the population of all the others.

When you get outside of these four provinces you get into sparse population; for example Mendoza, the center of the grape industry, has only 277,000 population in the province. It lies on the west, close to the Andes and nearly opposite to Buenos Aires.

Good Selling Grounds

The Province of Tucuman in the northwest and where the sugar industry is centered has 322,000 population. San Luis province which is proving a good selling field for American cars has 116,000 population. Pampa Central, another section midway between Buenos Aires and the mountains with 101,000 population, is proving a good selling ground.

The entire country needs automobiles, it needs motor farm tractors and it needs many light-capacity trucks as well as many heavy-capacity vehicles. There are large possibilities of business at the present time and with normal development which should follow soon after the war closes, there should be much more rapid progress.

We cannot estimate the future buying capacity from the past because of abnormal conditions and also because it is only within the last year that our low-priced cars have taken hold. During the first 3 months of 1916 Argentina imported 1462 automobiles, which is nearly as many as in all 1915. The 1915 figures were 1838 cars imported. The 1462 cars imported this year were largely American machines, the only European country furnishing a few being Italy. If this rate of importation continues for the remaining three-quarters of the year the figures will approach 550 machines, being higher than 1911, the year before the crisis and when the importations from Europe reached their zenith.

The figures of 1462 for the first 3 months of this year do not give an adequate conception of the demand there for American cars, because many dealers were months behind in deliveries, due to lack of shipping facilities from New York. Some dealers did not receive a single car in January and February, 2 of the best selling months, and were receiving cars in June that should have been on their selling floors Dec. 15. If Argentina could have received in January, February and March all of the American cars it needed the figures would have been double 1462. One Buenos Aires dealer received nearly 400 cars in May and June that should have been in his hands in January. He will be compelled to hold them to the opening of the selling season in November.

18,162 Cars in Three Months

In the last 5 years and during the first 3 months of this year Argentina has purchased 18,162 cars. The majority of these are European cars which gradually rose in sales until 1911 and have gradually fallen since. The importations for the different years are:

Year	Cars	Year	Cars
1911	2461	1914	3004
1912	4281	1915	1838
1913	5115	1916 (3 mo.)	1462

When these importations are translated into car values in dollars the figures show a great falling off. The European cars represented expensive machines, generally with costly limousine bodies made by the finest body builders in Europe. Against this you must contrast the low-priced American machines of the last 2 years.

Too much attention must not be placed on these figures. They are accurate, but must be interpreted in the light of the great change that has taken place with regard to American cars. In reading over these figures you must recall that our cars have started selling on farms, where cars never sold before. You must remember that, while our cars have been selling, storerooms have remained filled with expensive European cars.

These figures are more eloquent than they appear. They

Left—Studebaker salesroom in Tucuman, the capital of the province of Tucuman, and the heart of the sugar district. Right—Ford agency in Tucuman, showing heavy shutters for doors and windows when store is closed

are rather suggestions of what the future has in store. You must rather be looking ahead when contemplating on them than looking back to the figures of previous years. You must interpret them in the light of prejudices against our cars that have been overcome. You must recollect that these sales have been made in spite of the lack of roads. They have been made in spite of deep founded prejudices against our cars in all of the cities. They have been made in spite of depression due to the war. They have been made in spite of gasoline selling as high as 70 cents a gallon. They have been made in spite of freight rates of $1 per cubic foot instead of 35 cents. They have been made in spite of car prices having been raised. In this light the figures are eloquent in the meaning they convey.

Business Methods Win

These increases in sales have largely been made by two or three concerns who have gone into the Argentine in a business way and with a determination to build up a business there. They have generally opened their own branches, and, in short, established their own selling policies throughout the country. They have stocked up with a big equipment of spare parts and have demonstrated to the Argentine that they mean business and are there to stay. This impresses the Argentine. He delights in seeing the United States citizen or the citizen from any other country coming into his land to live. The Argentine is just as proud of his land as we are of ours and every permanent business investment of this nature pleases him and builds up that spirit of confidence which is so essential to Latin-American business.

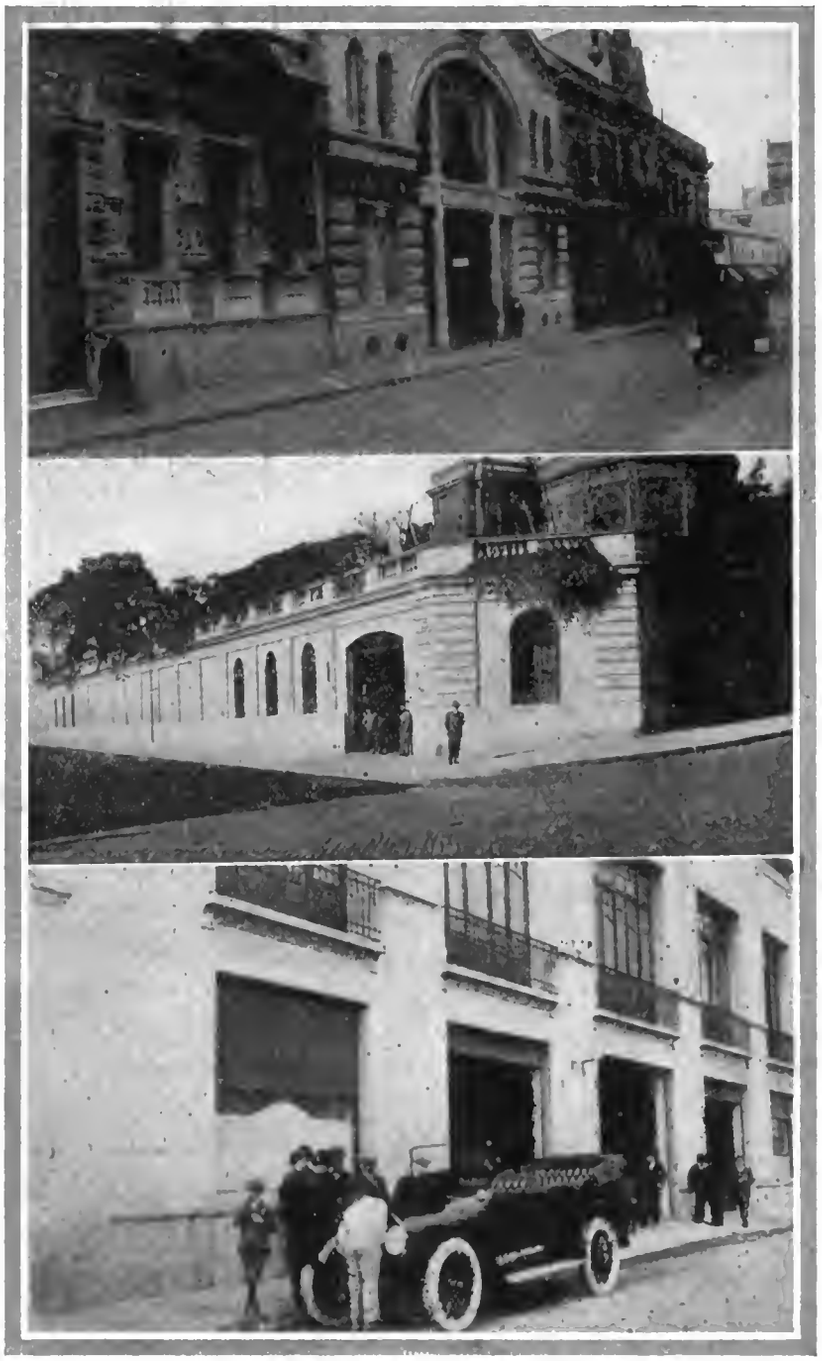
Basement of Ford Agency in Rosario, showing a small corner of spare-stock department. It is as orderly as in any U. S. A. branch

Spare Parts Essential

A good stock of spare parts is the biggest selling argument in Argentina for any American car. You realize the value of such when you think of 3 weeks to send a letter for a spare part on boat, 3 weeks more for it to return on boat, and then perhaps a week or so waiting for a boat. Add to this loss of time in customs and you are out of the use of your car for 2 months. In the United States with cheap telephone and telegraph arrangements your car would not be laid up for more than a day or so. It is no wonder then that any American automobile manufacturer contemplating going into the Argentine market must make up his mind to stock up with spare parts. If he does not he had better leave the market alone.

Further glimpses of the Argentine may not be amiss, for the sole purpose of this article is to give a clearer conception of the country so that its possibilities may be better understood.

Argentina is not a manufacturing country in that it has few minerals and little if any coal. Up to the war coal was all brought from England but since then the United States has been shipping all it can get ships for. The lack of coal will prove a serious handicap, but there are possibilities that electric power and petroleum may partly make up for this lack. There are great water powers well located and there are two different petroleum deposits, which, while they have not been well developed the feeling is that there is a good future for them. One is in the south at Rivadavia and the other in the north in Catamarca. The country to-day is a great cattle, sheep and horse country with much wheat, corn and other grains. It is a greater grain exporter than the United States. Unfortunately at present for Argentina Europe has been buying more grain from Canada and the United States, as the freights are shorter, and Argentina finds itself with much of the present stock stacked in sacks at the different railroad stations and much of it on the farms. There will be a very heavy grain loss, because the country is without a system of railroad grain elevators.



Top—The building with the arched entrance is an example of the newest style of Buenos Aires garage construction, with capacity for upward of 100 cars. Middle—Typical example of private garage, Buenos Aires. Bottom—Two-story Buenos Aires garage, with capacity for 100 cars. Electric elevators and all other modern conveniences are in use.

The country has many factories of varying kinds. There is a large boot and shoe industry; there are many flour mills; wood-working factories of different kinds are being built and a variety of others including dye factories, etc., are being established. Land heretofore has offered the greatest opportunities for wealth and it was but natural that little attention would be given to manufactories. With fuel shortage the handicap was greater. To this can be added sugar, wine, rice, hides, meat packing and other industries.

It is much easier to do business in Argentina to-day than it was a few years ago. Buenos Aires has a large branch of the National City Bank of New York. This bank, already in sixth position in a list of twenty, has a very elaborate credit department and has been pushing its commercial departments rapidly. The bank is prepared to give almost any information on credits and its establishment has greatly facilitated doing business with the United States. Through it any American maker can secure all necessary credit ratings. It used to be that before this only American bank was established money transactions had to go through London, Paris or Berlin. To-day it is as easy to do business from Buenos Aires to New York as to any of the European capitals. True, England, Germany, France, Italy, Belgium and other European lands have most of the banks well established and we have only one, but our start has been made and now the dollar is becoming known in Argentina as well as the pound sterling. The ice has been broken. The American maker has now adequate facilities at his disposal to do business.

Railroads and Hotels Good

American automobile makers will not have to confine their business in Argentina to Buenos Aires, but will find nearly a score of other cities in which agencies can be placed. There are already several agencies in such cities as Rosario, Cordoba, La Plata, Bahia Blanca, Tucuman, Mendoza, San Luis, etc. In the smaller places showrooms are not maintained, and often the car is sold by the firm handling National cash registers, Remington typewriters, or Singer sewing machines.

There are excellent railroad facilities to all of these cities; in fact, Argentina has good railroad systems and plenty of them. The sleeping cars and dining cars are as good as you get in Europe, being generally of English manufacture. You find satisfactory hotels nearly every place you go; in short, there are no serious obstacles to the general development of the business.

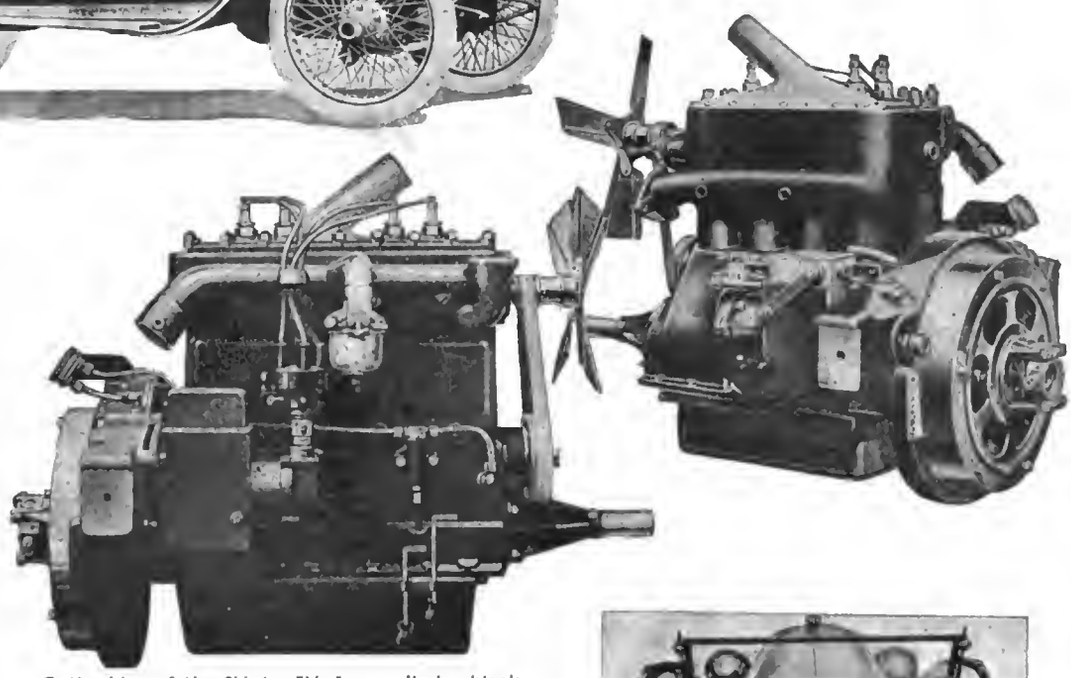
Perhaps roads, or the lack of them, is the heaviest handicap. They are utterly lacking in many places. The country has few real highways although there are some sections where road building is easy. Buenos Aires is located in a plain as level as Chicago. The soil is black loam and the rainfall fairly heavy. This is the richest section of the country and has the poorest roads. Three real efforts at road building have been made, but yet there is only one city you can tour to by motor car and that is La Plata, 65 miles, and the capital of the Province of Buenos Aires. There are two good roads there, roads as good as in the United States. One road is a new stone block one, not cobblestones, but a road as smooth as a brick pavement, which is just completed. It is ideal for motor truck traffic and equally good for passenger traffic. This road was built by a French engineering organization and resembles a railroad right-of-way. It is as straight as an arrow until lost in the horizon beyond. Mile after mile it stretches over the pampas in this straight course, and as level as a table all of the way. It is a beautifully built road with stone curbs on each side just like a city boulevard, and with excellent bridges every few miles in places. It is a monument to road building in South America.

There is another good dirt road built some years ago between Buenos Aires and La Plata which is a fine motor road, horses being barred from it. The wagon road was very wide, perhaps three times the width of an American road and the motorists got permission to build a motor road in the center of it. To-day the motor road is hard and dry, even after rains, whereas the wagon roads at the sides are literal quagmires after rains. The third road out of Buenos Aires leads to a great summer picnic ground.

Briscoe Brings Out New Four

3⅛ by 5⅛-In. Engine On 105-In. Chassis—Bailey Gearless Differential and Rear Axle Gearbox

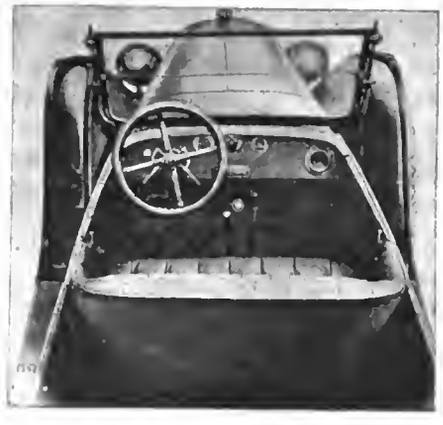
New Briscoe Twenty-four five-passenger touring car which sells for $625



Both sides of the 3⅛ by 5⅛ four-cylinder block engine used in the new Briscoe Twenty-four, showing mounting of accessories

BRISCOE has a brand new car fitted with a four-cylinder engine and priced at $625 with either a five-passenger touring or a four-passenger roadster type. It is a distinctive car in a number of respects, both in chassis design and body arrangements. The Briscoe Motor Corp.'s plan of quantity production is doubtless one factor which makes the price possible.

Following the latest body contour, the new Twenty-four, as it is called, has a rather high and narrow radiator, and a sloping hood and body. There is no transitory curve where hood joins body, and at the cowl, the body is rounded over in line with the present tendencies in body fashions. There is no doubt that body shaping has come to the point where speed is suggested in every curve, and it is to be hoped that the fashion will not change. The Briscoe designers have evidently caught the idea, for a distinct suggestion of speed and power is given by the lines of the new bodies. Then, a slanting windshield has been fitted, this alone being a sort of finishing touch to a very pleasing general body outline.



Illustrating the tapered stream lines of the new Briscoe touring car model

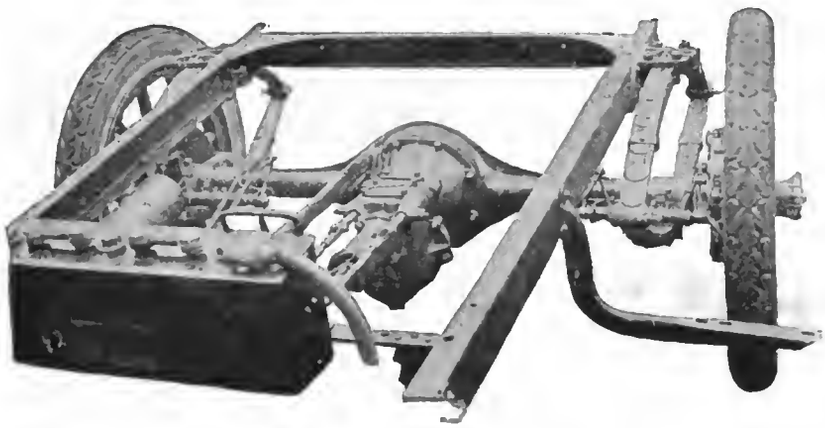
Ample Leg-Room

The new Briscoe is built on a wheelbase of 105 in., and the space has been commendably utilized to give a very roomy car. Like most other designers, the Briscoe sponsors have seen to it that the old criticism of not having sufficient legroom in the drive seat to give the driver comfort does not hit their new creation.

Looking at the mechanical specifications, we find a 3⅛ by 5⅛ four-cylinder block engine having a detachable cylinder head plate that gives access to the valves; an inverted type of cone clutch; three-speed gearset in unit with the rear axle; floating rear axle in which is incorporated the Bailey gearless differential; elliptic front and rear springs; tapered frame and 30 by 3½-in. tires all around.

From the above it will be evident that the engine has quite a long stroke as compared with the bore, the dimensions giving a stroke-bore ratio of 1.64 to 1, which is somewhat greater than the average. The formula accords the engine 15.64 hp., but it is capable of over 30 hp., due to the long stroke and general design. A better idea of this may be gained from the fact that while the bore is not large, the long stroke raises the piston displacement to 157.2 cu. in., which figure is a direct indication of the power.

Of the type in which the upper part of the crankcase, which carries the crankshaft and camshaft as well, is in unit with the cylinder block, the engine provides for quick valve accessibility by the use of a detachable plate that extends the length of the top of the casting over the eight valve chambers,



Rear of Briscoe Twenty-four chassis, showing rear axle gearbox, unusual spring mounting, etc.

this being on the right half of the top. The left part of the top is taken up by the large water outlet connection which works in conjunction with thermo-syphon cooling. The bottom of the engine is inclosed by a pressed steel pan which acts also as the oil reservoir. On the right is carried the Splitdorf gear-driven generator, with the ignition distributer mounted in unit, and on the left is the starting motor, also a Splitdorf unit. It connects to teeth in the flywheel face. The right side being the valve side, the manifolds are placed here, with the carbureter mounted quite high up so that there is no interference with reaching the tappets.

Rear-Axle Gearbox

Since the gearset is not in unit with the engine, but occupies a position as a part of the rear axle, the flywheel is uninclosed.

With direct oil feed to the bearings and gears, the lubrication system is a combination of splash and force feed. The oil pump is positioned on the right forward side of the crankcase and is driven off the camshaft. The oil leads to the gears and sight feed gage run outside on the right. In accordance with usual practice for this kind of oiling, the troughs under the connecting-rods are kept supplied, and the rod ends throw the oil up into the cylinders and onto the various bearing surfaces, from which it eventually drains back into the crankcase. To tell the height of the lubricant in the supply, there are two indicating levers located on the right side of the motor just below the oil pump. There is also an indicator which tells whether or not the oil is flowing as it should. This occupies a rather unusual position, in that it protrudes through the toeboard within sight of the driver, and ahead of the control levers. Thus it is out of the way and can be readily seen, but the piping is reduced to the minimum, which is a commendable point. The oil filler and breather is in a new place too, it being forward on the right, and high up so as to be accessible for oil filling. It enters the cylinder block just below the exhaust manifold, and above the cover plate that houses the valve tappets.

Thermo-Syphon Cooling

In its adaptation of the thermo-syphon method of cooling, Briscoe has placed the engine sufficiently low as compared with the radiator to give proper thermal action. To further meet the demands of this simple cooling, the radiator top tank is large, and the water flows to it from the large water outlet connection that extends the length of the top of the cylinder casting, as already pointed out. There is also a large water inlet which is attached to the left side of the cylinder block, and extends all along it so as to give good water distribution, and further it is of sufficient size to insure against restriction of the flow. Thermo-syphon cooling is very efficient for engines of this size where it is properly applied, and Briscoe engineers have evidently been fully aware of the possibilities of correct fitting of the system, judging from the free passages, large size, etc. A four-bladed, pressed-steel fan is applied, driven from a pulley on the front end of the camshaft by a flat belt. The fan is mounted in a support that is integral with the cylinder casting, and there is provision for rocking the fan shaft so as to give the right belt tension.

Drive of the generator is unusual, for it is from the rear end of the camshaft through gear connection. The generator is positioned close to the flywheel on the valve side of the engine, and the gearing is housed in the extension of the right rear supporting arm of the engine. The ignition distributer is mounted on the front end of the generator unit, and there is bevel gear driving connection between its vertical shaft and the horizontal armature shaft, insuring positive and silent drive at all times.

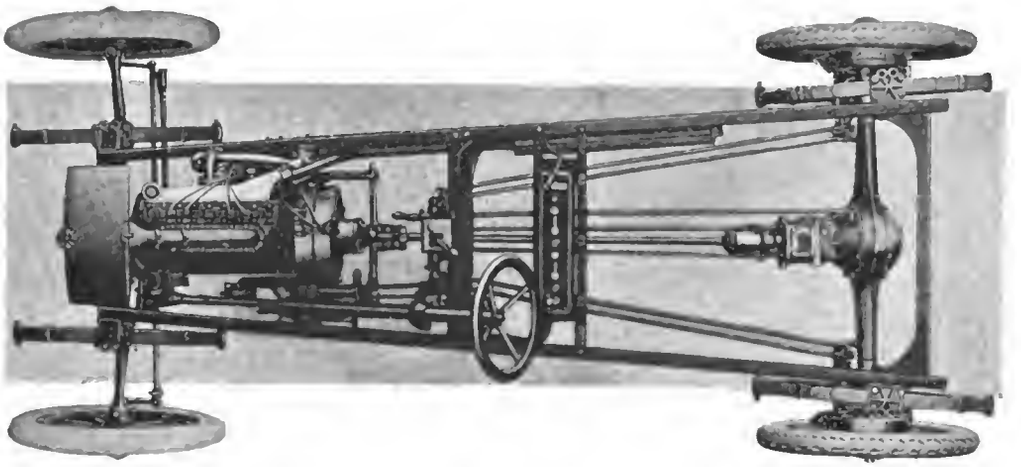
Passing to the clutch, this unit also presents some differences over average practice, principally in the fact that it is of the inverted variety. That is, instead of pulling back from the motor to release, it is shoved toward the cylinders, the action being just the reverse. The cone is leather faced, and is possessed of six spring plungers acting against the under side of the leather at equal intervals to insure easy action and prevent grabbing. As the throwout mechanism must act to push the cone inward when declutching, a simple universal coupling acting directly against the center of the cone and clutch spring is made possible. A forged arm extends out from either side of the engine support, and the pedal shaft is carried transversely by these arms, the center of this cross shaft having a simple leverage connection with the clutch coupling. The construction should make a pedal action that does not require undue foot pressure, although exerting a multiplied force on the cone.

Back of the clutch there is a universal joint and then the open driveshaft runs directly back to the rear universal that is just ahead of the gearbox. There is a light torsion bar running from the front of the axle housing to the intermediate frame cross member, this assisting in taking the torque and drive. Compactness is very noticeable in the gearbox, which has three speeds, with the countershaft mounted directly below the mainshaft. The latter runs on taper roller and ball bearings, while the countershaft is carried on plain bushed bearings. Control rods run parallel with the driveshaft from the H-gate that is attached for-

Briscoe four-passenger body, showing how the hinged upholstery in the center of the front seat back furnishes an aisleway to the rear seat

ward to the intermediate cross member of the frame. These control rods are of quite large diameter, and should not have any tendency to whip, and special provision has been made in their mounting so that there is no likelihood of rattle.

Although the pressed-steel rear axle presents no unusual features outwardly, it is fitted with the Bailey gearless differential, which acts through a series of ratchets and pawls, so that the wheel having the most traction gets the most power, in contradistinction to the standard differential in which the free wheel receives the bulk of the power. The axle possesses the qualities which put it in the floating class, in which the weight of the car is carried entirely on the axle tubes, with none to be sustained by the axle shafts, they being given the single function of driving the wheels. Hyatt roller bearings carry the axle shafts, acting in conjunction with ball-thrust bearings which care for the thrust.



Chassis of the new Briscoe, showing the taper frame, layout of the power plant, rear axle gearbox, and mounting of the springs

Easy Riding a Feature

Easy riding is featured in the new Briscoe, due largely to the use of full elliptic springs both front and rear, with special attention paid to the attachment of these suspending members so that they have free action. The rear pair are underslung from the axle, and substantially joined to the frame by brackets of ample proportions that extend out from the side frame rails in close proximity to the rear cross member, being the place where the frame is well braced to take care of the load imposed. The front pair attach similarly at the extreme front end of the side members.

A straight taper is given the frame from front to rear, thus allowing for a moderate turning diameter, and for rigid attachment of the narrow radiator that fits snugly between the side members. Besides, a sloping frame makes the best kind of support for the tapering body, holding it well along its entire length.

In this chassis, the storage battery support is given much attention. There are two cross members utilized as a cradle for the long and narrow U-S-L battery that extends up under the front seat of the body. The battery maker cannot find any fault with this rigid battery foundation, and it should be a factor for prolonging the life of the storage cells.

Four-Passenger Body

The four-passenger body is deserving of special mention on account of the originality displayed in the arrangement of the front seat back. Of the sociable type with the rear seat close up to the front the aisle between the two front seats which allows access to the rear seat, is normally closed by a hinged portion of the back of the forward seat. This, when in closed position, affords a back rest all the way across the front seats, but when it is desired to get into the rear compartment, the entire center upholstery section hinges out of the way and gives an aisleway that is amply wide to permit ready passage. The rear of the body has a torpedo shape, and altogether the four-passenger body should prove a very attractive model.

All the fitments and standard equipment of the modern machine are included in the makeup of the Briscoe, and while wood wheels are standard, wire wheels, which to many add a touch of distinction, may be had at an extra figure.

---

129 Makes of Trucks in Kansas

ACCORDING to an analysis of the registrations of motor trucks in Kansas made recently there are 129 different makes of commercial motor vehicles in use in that State. Of the total of 1639 vehicles, Ford delivery cars lead with 488, International 286 and Buick 145. Reo has 96, Studebaker 47, Overland and G. M. C. each 36, Avery 31, Republic 28, Cadillac 26 and the rest, headed by Packard, Velie and Koehler with 18 each, range down to 56 makes with one each.

Aland Sixteen-Valve Four

New Detroit Production To Have Racing Type Aluminum Engine—Diagonally-Connected Brakes on All Four Wheels

FOR the last few months there has been considerable talk of sixteen-valve four-cylinder cars, and the latest of these to be mentioned is the Aland, made by the Aland Motor Car Co., Detroit, Mich. This concern is just organizing and expects to be in a position to start manufacture about Dec. 1. The company is incorporating under the laws of Michigan with a total capital of $500,000.

The line will be made up of one chassis model with several body styles, but production will first be started on a five-passenger touring car and a two-passenger roadster. The paramount feature of the design is the use of a high-speed sixteen-valve aluminum engine, and in keeping with the intention to have the weight as low as possible throughout, the car will be characterized by a liberal use of high-tensile steel. Throughout the entire design the matter of price will be a secondary consideration and as a result this has not been definitely fixed, although in all probability the car will retail for about $1,500.

65 Hp. at 3200 R.P.M.

While rated at 14 hp., according to formula, the manufacturers state that the engine will develop more than 65 hp. at 3200 r.p.m. The cylinders are cast in a single block and made with the crankcase as an integral part. This is an aluminum casting and the cylinder walls are provided with cast-iron sleeves which are pressed into place. The bore of the engine is 3 in. and the stroke 5½, giving a piston displacement of 155.5 cu. in. and, according to the maker, 1 hp. from every 2.39 cu. in. of displacement. This high efficiency is explained by careful attention to balance and to the high volumetric efficiency due to the extra large valve areas and the fact that there are four valves per cylinder. Each of these valves is 1 7/16 in. and opens directly into the combustion chamber being operated by an overhead camshaft which is located in the alley between the valves. One cam operates two valves through double rocker arms which are provided with roller followers at both ends to minimize friction. The rockers are offset 2 to 1, so that, while the cam lifts the rocker but 9/64 in., the valve is lifted 9/32 in.

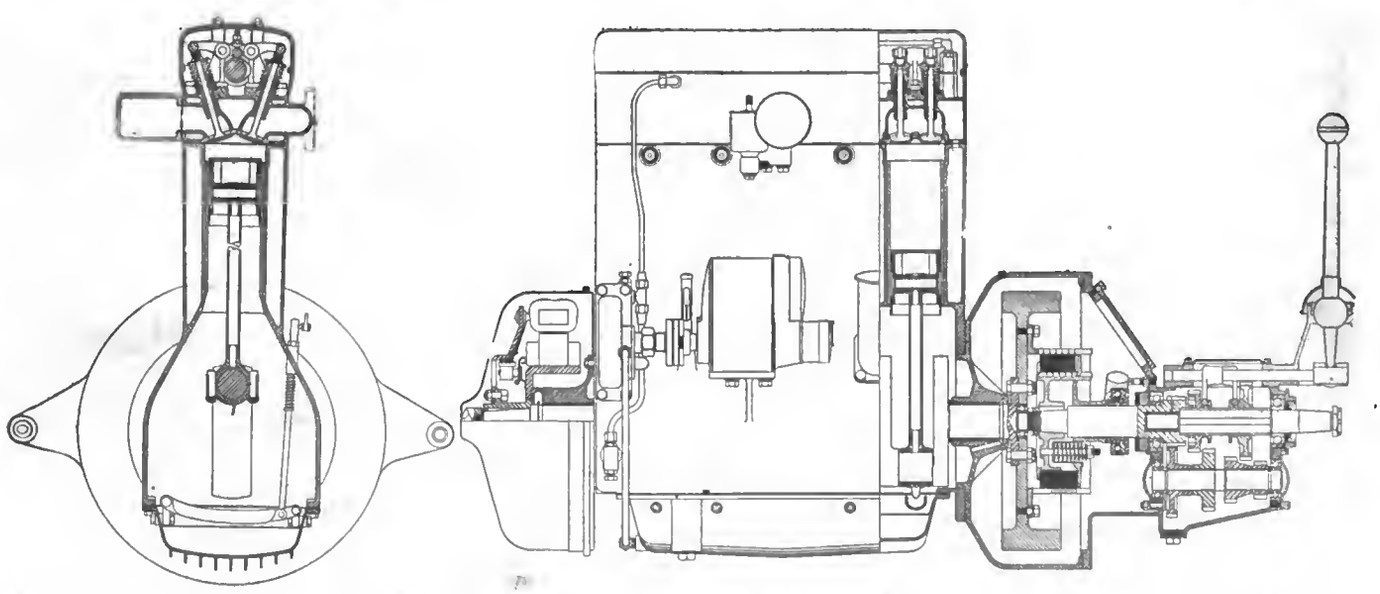
An aluminum alloy casting is also used for the cylinder heads. It is held in place on the cylinder block with twelve 7/16-in. nickel-steel studs placed in such a position as not to interfere with water circulation and to be accessible. This cylinder head casting contains the valves, springs, guides, brackets, camshaft, etc., and forms a separate unit which can be removed without disturbing any adjustment. A feature of importance is that the entire valve mechanism runs in a bath of oil and is protected from dust by means of an aluminum cover which fits over the entire top of the engine block.

Tubular Connecting-Rods

Aluminum alloy is used for the pistons which are provided with three rings, two above and one below the wrist pin. A groove is cut in the piston below the bottom upper ring with six small holes drilled into this as an extra precaution against superfluous oil.

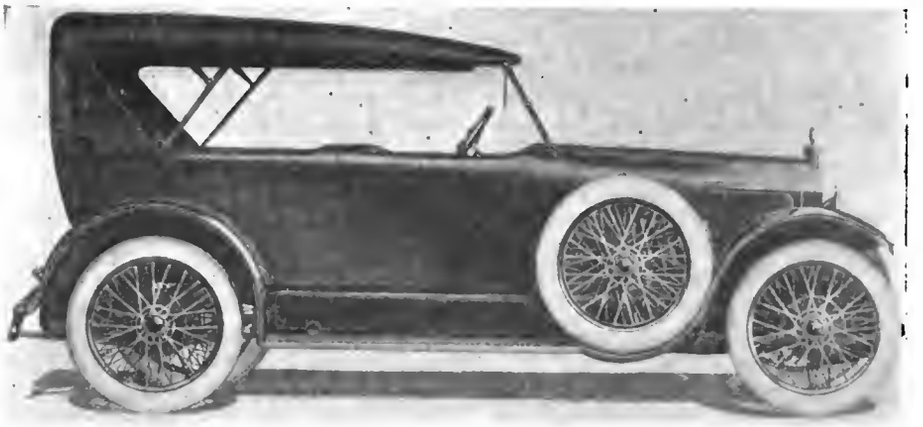
A nickel-steel wristpin is used and this is free to oscillate in either the connecting-rod or the piston. A small steel ring fits into a groove on either side of the wristpin and prevents it from working out to one side and scoring the cylinder wall. The upper end of the connecting-rod is provided with a bronze bushing and the connecting-rods themselves are of tubular type made from chrome vanadium steel. In manufacture it is purposed to pay particular attention to the balance of these parts and also to make them secure against breakage. Nickel-steel bolts are used to hold the cap on the lower end of the connecting-rod and throughout the sections are such as to provide a good factor of safety.

Three bearings support the crankshaft. This is of chrome vanadium steel, heat treated and balanced so as to be in



Showing the simple character of the Aland overhead camshaft engine. Observe the U. S. L. starter at the front end of the crankshaft

running equilibrium at 4000 r.p.m. The shaft is machined all over and at the rear is fitted to a cast-iron flywheel, while in front is the U. S. L. starting and lighting system, which is not in this case a flywheel installation. The unusual installation of the U. S. L. starting and lighting system on the front end of the crankshaft is quite accessible and in this case a stamped steel housing incloses it.



Aland four-cylinder, five-passenger touring car

Has Diagonal Brakes

Another novelty in American design is the use of diagonally connected brakes on all four wheels. This system was originated by the Argyll company in Scotland and operates as follows: The right rear and front left brake are interconnected and operated by either foot or hand, while the left rear and right front are operated by the other control. The effect of this is that, when applying one brake, there is left on either axle one wheel which is rolling free and therefore has the maximum ability to keep the car traveling in a straight line. With this diagonal arrangement it is possible to lock one wheel on each axle and still have control over the steering. The four brakes are all expanding types and act equally well whether the front wheels are straight or at an angle.

Naturally with such a high speed engine, lubrication has been carefully studied. Oil is first pumped from the cast aluminum pan which has a capacity of 6 qt., to a distributer tube cast intregal with the cylinder block. On the top of this tube is located the pressure regulator for the overhead compartment, and a small tube delivers oil to the camshaft bearings and other valve parts. A vertical lead directly over the center crankshaft bearing carries the oil back from the overhead compartment to the crankshaft, lubricating the center bearing. In addition there are adjustable troughs beneath the crank throws which take care of the wearing surfaces within the motor and the front and rear main bearings are oiled by separate leads from the oil pump distributer. Beneath the troughs and extending the entire length of the crankcase is a strainer which is readily removable for cleaning.

Three point suspension is used with each point allowed to move, as each is mounted on a swivel. The two rear points are fastened to the steel stamped supports by means of self-lubricating bolts. The front end is bolted to a cross member at the center and the flywheel is completely housed within the cast aluminum bell housing, the gearbox and clutch case bolting directly to this to form a complete unit power plant.

A Raybestos-faced multiple disk clutch is used with alternate disks of steel and the clutch release is provided with a ball bearing, so that only light pressure is needed to release the clutch. The gearbox is a three-speed selective type with gears and shafts of chrome-nickel steel. The shafts are mounted in large double-row, self-aligning ball bearings.

From the gearbox the drive is taken to the rear axle through a large diameter nickel-steel tube with universal joints at each end, both drive and torque being taken in Hotchkiss style through the springs. The rear axle is semi-floating and is equipped throughout with Timken bearings. The driving gears are spiral bevel and a bearing is located on either side of the pinion, giving a substantial mounting and also shortening the pinion shaft and decreasing the amount of axial movement of the rear universal joint.

A bottle neck frame is used, allowing a wide rear which conforms to the shape of the body sills, narrowed at the front to allow for a short turning radius; in fact, the makers state that the car is able to turn about in a radius of 16 ft. 4 in. In carrying out the construction all the frame cross members and brackets are hot riveted in place, the spring horns at both ends being provided with bronze bushings.

The springs are semi-elliptic all around and are designed to be approximately flat under load. The rear springs are 55 in. long and 2 in. wide and are underslung. The front springs are 37 in. long and 2 in. wide. The springs are attached to the frame by forged shackles and these also are provided with self-lubricating bolts. A full set of shock absorbers is provided as standard equipment.

Conventional steering is used with worm and full gear and adjustments to take up wear at different points. The steering wheel is an 18-in. walnut nobby grip and the control levers work on a full circle control plate instead of the conventional sector.

On this chassis, which has a wheelbase of 122 in., there will be several types of bodies which will be interchangeable. The five-passenger open touring and the two-passenger touring roadster will be the first in production. The five-passenger design is featured by a deep cowl with a built-in sloping windshield. The body is a double cowl style and is made of sheet aluminum over a sub-structure of wood. The seats are low and are tilted back to give ample leg-room. A great amount of attention has been paid to detail in equipment and the car is provided with five Rudge-Whitworth wire wheels with 33 by 4 tires.

—

Efficiency versus Neatness

THERE is one respect in which many motorists of experience find a criticism for the modern speedometer despite its better durability and greater accuracy. This is in the nature of the dials employed. The almost universal style to-day is the horizontal indicator which brings different figures opposite a little "window" in the cowl board. This is much neater than the old style full dial with a moving pointer and the speed figures set around like those of a clock, but the latter scores heavily when the driver wants to read the dial quickly.

With the old pattern instrument it was not necessary to look directly at the dial. After using the car a short time the speed could be seen out of the corner of the eye, as the position of the pointer told the driver what speed he was making without his having to actually read the figures. With the modern design the figures must be read, and though this takes but an instant's glance, yet it does demand greater concentration of thought than did the old pointer.

The pointer pattern of dial could be made as neat as the other with a little ingenuity, and there are many who believe that its real superiority will bring it back again, even if not for some years to come.

Make and Break Both Positive

New Idea in Timer Distributers Has Contacts Brought Together and Separated Independent of Spring Action—Very Rapid Operation Possible

A BREAKER mechanism for an ignition distributer in which both the make and the break are positive mechanical operations, neither depending upon the rapidity of action of the spring, is the briefest possible description of a new device recently evolved by the Pittsfield Spark Coil Co., Pittsfield, Mass.

Despite its unusual action the device is extremely simple and it is explained by the series of diagrams in Fig. 2. The essential feature is the use of the two stout spring steel pieces *A* and *B*. It will be noticed that each of these carries a contact point and that *A* is longer than *B*. The cam shown is square with rounded corners, but it would be, of course, hexagonal for a six-cylinder engine, octagonal for an eight, and so on.

Striking radii from the center of the cam and considering the three *R*, R_1 and R_2, it is obvious that R_1 is the longest, while *R* and R_2 are of equal length.

As the corner of the cam sweeps past the free ends of the springs they will be lifted and, if the rotation is in the direction of the arrow, *B* will begin the lift first, while *A* will lift a trifle later. In the middle diagram of Fig. 2, the parts are shown in the position where the end of *B* is just in contact with the end of the radius line R_1. At the same instant *D*, the extremity of *A*, will be in contact with the cam at the end of the radius *R*. This means that with the cam in this position *B* has been lifted to the highest point which it will attain, while *A* still has some short distance upward to travel as the cam turns further around.

The clearances are so arranged that the amount of advance lift given to *B* is just sufficient to raise it until the platinum contacts meet. In other words, *D* is lifted out of contact with the cam just a hair's breadth when *B* is at its extreme limit of travel.

If the cam goes on turning it is obvious that *B* will fall again by the action of the spring, which would break the points apart, but this is not relied upon, as the spring cannot act quickly enough. Suppose *B* remains suspended in the air after the corner of the cam has passed on; that the spring only acts quite slowly. Now turn back to the middle diagram of Fig. 2 and consider *D*, the end of blade *A*. As soon as the cam turns into the position shown in the right-hand diagram of Fig. 2, *D* must be lifted, and blade *A* will thus be raised so high that the contacts will separate even if *B* has not adhered to the cam because of sluggish spring action.

Fig. 1—Pittafield distributer complete and with the breaker mechanism removed, the method by which the breaker box comes off is obvious. The coil is contained in the upper part of the body which is stationary, only the breaker moving to give advance

Putting this another way, in Fig. 1, first position, both *A* and *B* are resting on the side of the cam and the platinum points are not in contact. As the cam turns it first lifts *B*, bringing the points together. This causes *A* to be lifted, thus keeping the contacts together with a firm pressure. Immediately the point of the cam strikes *D* the circuit is broken,

(*Concluded on page* 191)

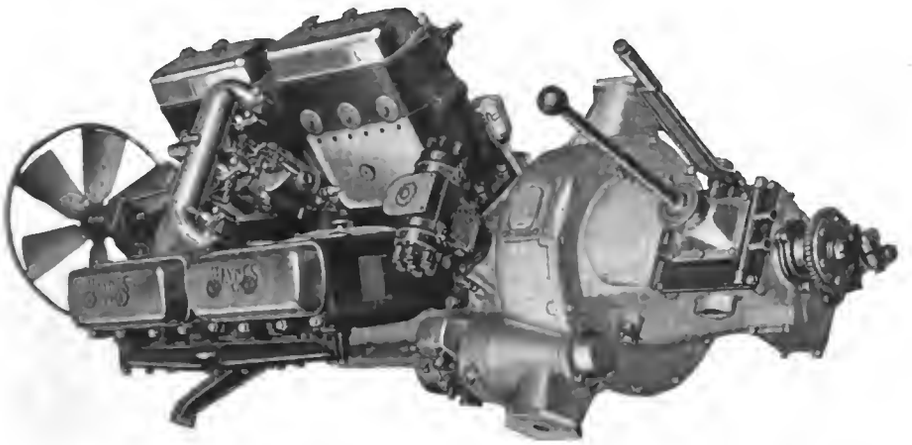
Haynes Light Twelve in Production

2¾ by 5-In. V-Power Plant Is Interchangeable with Six-Cylinder in One Chassis—Six Is Continued Without Change



Rear view of the twelve-cylinder engine used in the Haynes Light Twelve. It is 2¾ by 5 in. and has a piston displacement of 358 cu. in.

ALTHOUGH the Haynes twelve-cylinder motor was exhibited at the New York show and elsewhere on the circuit last January, production on a complete twelve-cylinder car has not been started until the present time. In producing this model, which has been given the title of the Light Twelve, the Haynes company has combined two existing units, the twelve-cylinder engine and the chassis used for the six-cylinder model, which has been continued without change.

Front view of five-passenger Haynes, showing caster-type front axle

Greatly increased floorspace, due to the addition of several new buildings, has increased the facilities of the plant to such an extent that the demand for the six can now be taken care of and the twelve also manufactured. The fact that the two power plants are interchangeable has also enabled the manufacturers to unify their production scheme to such an extent that all that is necessary in the way of more room is that required for the manufacture of the engine. Even the bodies of the two cars are similar.

In the design of the twelve-cylinder engine every attention has been paid to maintaining lightness. Throughout, all the requirements of high-speed motor design have been followed with particular attention being given to light reciprocating parts and ability to accelerate. The cylinders are cast in two sets of six and are of valve-in-head construction with removable cylinder heads. As required by twelve-cylinder timing, the two blocks are set at an angle of 60 deg. on the base. A piston displacement of 356 cu. in. is given by the twelve 2¾ by 5 in. cylinders. This gives a formula horsepower rating of 36.3.

Pistons Are Aluminum

In manufacture each of the cylinders are ground separately after the completion of the boring operation. The pistons are aluminum and this fact coupled with the small bore gives a very light stress on the bearings in transmitting the forces of the explosion strokes. Three patented rings are used on each piston and in addition there is an oil groove to prevent the flooding of the combustion chamber.

Owing to the light stresses due to the moderate bore and light reciprocating parts, it has been found practicable to use a side-by-side connecting-rod construction. With this arrangement the right set of cylinders is moved back the width of a connecting-rod bearing toward the cowl, thus giving an offset or staggered arrangement to simplify the lower rod construction The same type of crankshaft is used on the twelve as on the six. This is a three-bearing shaft drop forged from 0.40 to 0.50 carbon steel subjected to heat treatment and carefully balanced.

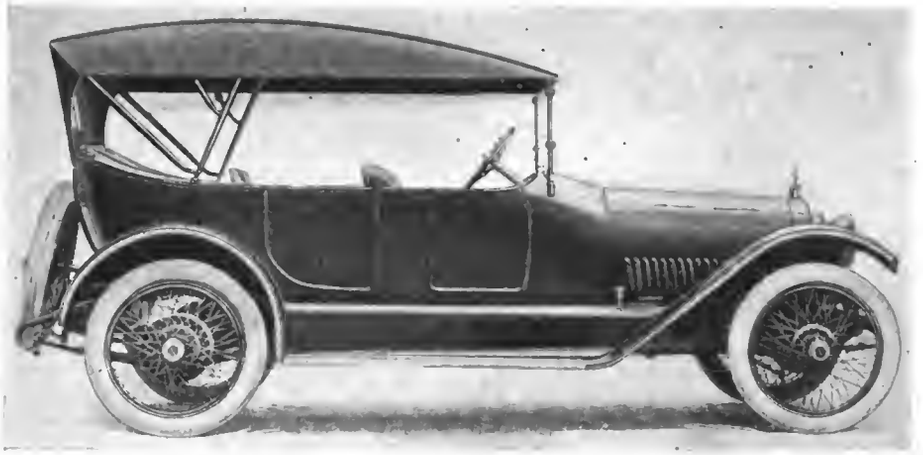
Valves Overhead

In working out the valve arrangement the overhead position has been selected, due to its accessibility and also for the advantages of combustion chamber shape. With the valves carried in the head the intake manifold is short and the exhaust is on the outside with the pipe at the center of the manifold. Thus the exhaust gases are carried straight down and back under the car at a sufficient distance from the driver's compartment to obviate the possibility of the heat entering the body. Another advantage gained by this arrangement is the neat layout of accessories permitted. The carbureter is hung from the short manifold in the center of the V in such a high position that it is quite convenient on lifting the hood. The ignition apparatus consisting of the timer and distributer is also mounted between the V and the water pump, generator and air pump are all accessibly mounted along the side of the engine and can readily be reached or even removed without interfering with any other parts.

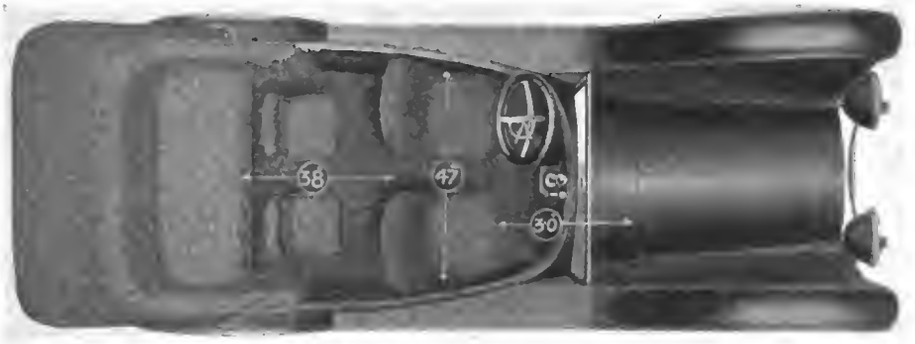
None of the parts of the valve action is in any way interfered with by the accessory mountings. The camshaft is placed at the center line so that the valves for both cylinders are driven off a single shaft. The valves are placed in the removable head and adjustments are readily accessible.

Pressure-Feed Oiling

Lubrication is by pressure feed, the lubricant being circulated by the gear pump through the hollow crankshaft. From this shaft there are outlets into all the bearings and those which are not reached by the crankshaft leads are fed



Haynes Light Twelve seven-passenger touring car which, with complete equipment, sells for $1,985. Wire wheels are regular fitments on this car. Goodyear 34 by 4½-in. tires are used



Plan view of the seven-passenger Haynes touring car, showing the seating arrangement and giving an idea of the liberal body dimensions, insuring comfort to driver and passengers

by small oil pipes. There is an indicator on the cowl which informs the driver of the condition of the lubricating system and of the pressure under which the oil is being fed.

Electrically the Haynes twelve is very much the same as the six. The Leece-Neville starting and lighting system is employed, while for ignition there is a double Delco distributer mounted as described. In the starting and lighting system the motor and generator are in separate units with a Bendix gear attachment for the starting motor which engages the flywheel. The generator is mounted on the same shaft which carried the water pump on the right side of the engine. A feature of the system is the use of an automatic circuit breaker which takes the place of fuses. As soon as a short circuit occurs on the line the circuit breaker opens, and after the trouble is remedied, the circuit breaker can be again closed by simply pressing a button. Gasoline is fed by the Stewart vacuum tank which is mounted in the V on the twelve.

On both the twelve and tbe six a three-plate-dry-disk clutch is used completely inclosed in the flywheel housing. It can be adjusted by the removal of a cover plate which incloses the mechanism so tbat it cannot be reacbed by water or dirt. A lining of Raybestos is mounted on a floating member to clean the plates of the clutch and this member takes all the wear. No oil is used on the friction surfaces of this clutch, so that it requires little attention, but when adjustments are necessary they can be made by lifting the floorboard of the front compartment, removing the cover plate and turning the two adjusting bolts. It is stated that adjustment can be made on this clutch in from 5 to 10 min.

From the clutch the power is transmitted to a three-speed selective gearbox, the gears in which are cut from drop forged nickel steel blanks and the shafts are also of nickel steel and are carried on large Gurney ball bearings. As is customary in unit power plants the shifter mechanism is all mounted in the cover plate. A ball-topped shifter rod is used pivoted at the floorboard line by a ball and socket joint.

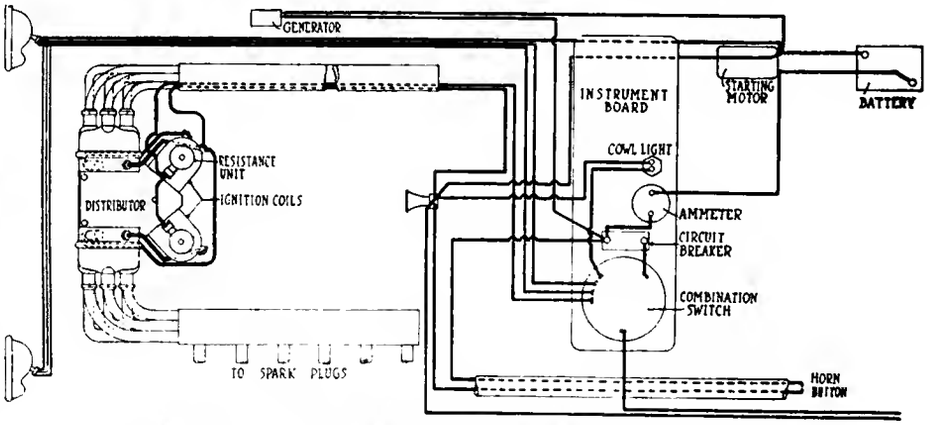
Axle Is Floating

Two universal joints are used in the drive, one being mounted at each end of the propeller shaft. The rear axle is floating and is a design which is manufactured entirely in the Haynes plant. Although the shafts do not carry any of the car weight, but only transmit the driving torque, they are of large dimensions, being 1½ in. in diameter and of heat-treated nickel steel. Spiral bevel drive gears are used with the pinion gear and shaft also of heat-treated nickel steel. A feature of the rear axle is that the entire differential can be removed by taking out four nuts that retain the bearings. This can be done without removing the axle. There are also adjustments in any direction for mesh between the driving pinion gear and the large ring gear on the differential.

Both service and emergency brakes are expanding and are set side by side on the inside of a 14-in. drum. With this arrangement they are both completely inclosed and protected from mud. The brakes may be taken up from the outside to compensate for wear of the shoes.

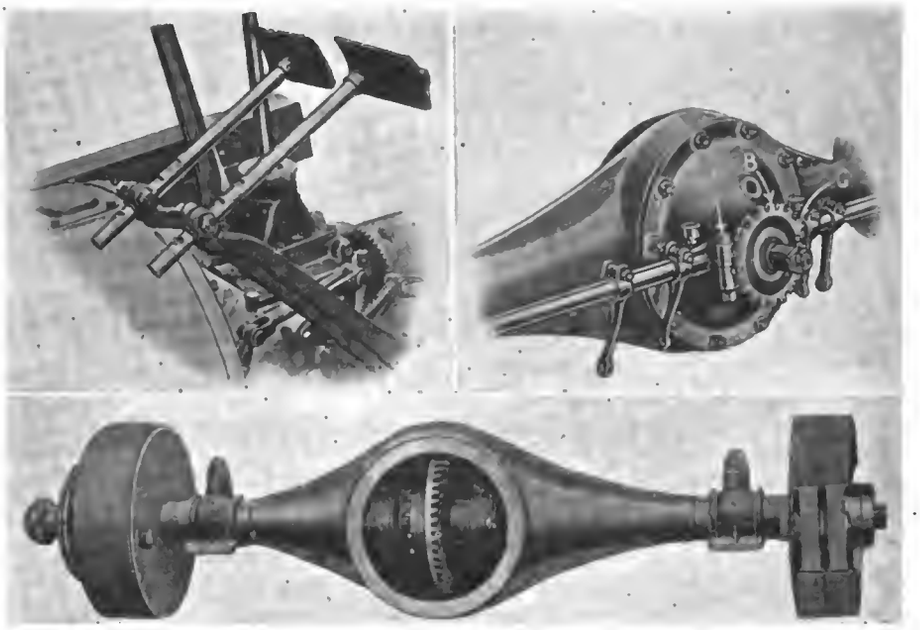
On the twelve, wire wheels will be part of the regular equipment. The tires are Goodyear cord 34 by 4½. The front axle is an I-beam, inclined to give a caster action to the wheels. The wheel spindles and steering knuckles are heat-treated, drop forgings of nickel steel. The front wheels run on two sets of bearings, one set containing ⅝-in. in the other ¾-in. balls. Both of these ball bearings are arranged to have a thrust or axial component as well as radial.

In equipment the twelve-cylinder cars are complete, being fitted with all the attachments customary on the up-to-date



Wiring diagram of the Haynes chassis for 1917, showing the connections for ignition, starting, lighting, etc.

car. In regard to convertible bodies or demountable tops, eitber the Haynes twelve or six can be so fitted in a short time. These tops are known under tbe trade name of De Luxe and are made up in both demountable sedan and coupé styles. The interiors are trimmed in gray whipcord. The back and side tonneau windows are fitted with roll silk curtains and there is an electric dome ligbt. The frame work of these bodies is made up of hard wood and the side panels and door frames are of ridged 2-in. stock. On the touring models the forward side panel is curved with the body line and ¼-in. polished bent glass is used in the windows. The demountable sedan tops for the five and seven-passenger touring cars and tbe coupé top for the roadster models are priced at $275.



A few details of the Haynes chassis, the illustration at the upper left showing the arrangement of the pedals, that at the upper right the differential pinion engagement and the one below depicting the floating rear axle which is made in the Haynes shops

Regular body styles for the twelve-cylinder model are five and seven-passenger touring cars and the three-passenger roadster. On tbe touring bodies there is an aisle between the front seats, and both tbese front seats are adjustible forward and back. The roadster is a clover-leaf with tbree individual seats and the center seat set directly back between the front seats. The wheelbases with these bodies vary, for the five-passenger touring car and three-passenger roadster it is 121 in. and for the seven-passenger touring car 127 in. The price for the five and seven-passenger cars and roadster is $1,985. This figure includes motor-driven tire pump, complete body equipment, full lamp equipment, horn, tools, wire wheels on the twelve and a Boyce Moto-Meter. The standard colors are Brewster green with black running gear and the finish of tbe car is of a high order of merit.

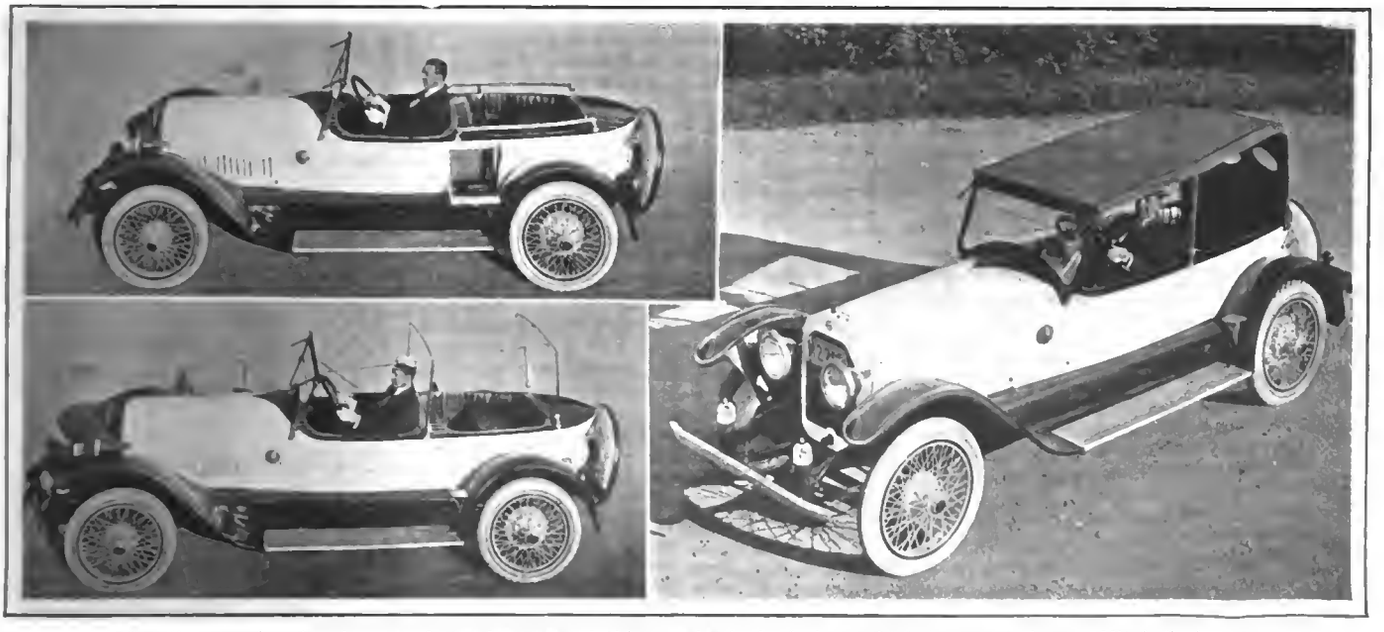
Boat Type Body on Mitchell Chassis

A BOAT body of unusual ingenuity has been designed by J. A. Clark of the Carl H. Page Co. for a Mitcbell chassis. The car was designed for the use of Mr. Page and will seat six passengers and a child. The lines follow those used in launch work, and the finish is in white enamel for the body with the upholstery and running gear of the same sbade of green. Wheels are Houk wire.

Ordinarily the car is adaptable for four adult passengers, the rear and front seats holding two apiece. In addition there are two concealed seats which let down from the sides of tbe body. There is also a child's folding seat in the forward compartment.

The top is invisible when it is not in use, and the bows which support it are folded down and are similar to the deck rails on the side of a boat. The top can be used as a sunshade, without the side curtains if desired.

Another ingenious feature is the single door entrance. A door back to the front seat, giving access to tbe rear.



The disappearing top is one of the features of this special body design, which is mounted on a Mitchell chassis

Advantages of Caterpillar Tractors

Special Work Can Be Done By This Type Which Wheeled Machines Cannot Accomplish — Type Worthy of Development—Automobile Engineering Experience Would Effect Vast Improvements

PART I

THE earliest systems of mechanical traction on a commercial scale were all steam operated, because at the time the steam engine was the only motive power which had been developed to a reasonable state of efficiency. Early types of road locomotives, both as tractors and steam wagons, were developed, principally in England, which country carried out the exploitation of the road steam engine to a far greater extent than one is able to find in other countries. Such a power unit was inherently cumbered by a large mass of metal, constituting the boiler and tanks, which caused its weight to grow out of proportion to its power production. In other words, the weight per horsepower of the steam-traction engine, fully loaded with fuel and water and ready to run, soon became of such proportions that its possibility as a commercial article was limited by reason of the conditions of roads and bridges. Some years ago it was obvious to the student of locomotion that such a type of tractor was doomed, except in a few special cases, and these are principally concerned with the question of fuel supply. It is a notorious fact that the steam-traction engine and the steam wagon will operate at a very low fuel cost as compared with other types of machines doing a similar class of work. On the other hand the steam-power unit requires considerably more attention and suffers from stand-by losses, which latter are nonexistent with the internal-combustion type of motor.

The fuel consumed by the steam tractor is of a bulky nature, and together with the water necessary for the boiler requires the services of three to five men and two to four horses for the haulage of supplies. The question of water becomes a serious one in a dry country, and there is also the delay in getting up steam pressure each day.

Against this the gas tractor can carry in its own tanks sufficient fuel and water for a day's run and one two-horse load of fuel will be sufficient for several days' working of the engine. Further, one operator cannot only attend to the tractor, but frequently is able to work the agricultural appliance as well.

Weight Prohibits Steam

Although we are not at the moment concerned with a comparison between steam power and anything else, it has been necessary to make this slight digression in order to appreciate one important line of development which has been necessary as the power unit increased in weight. The large steam-traction engines made in England have a weight as high as 60,000 lb., which is principally carried on one pair of driving wheels. Such a weight as this is entirely unnecessary in the construction of any machine of the internal-combustion type built in accordance with modern practice and giving the power output that is usually demanded from a single unit.

When we consider weight, two factors must be borne in mind. The first is the provision of a sufficient amount of material in the general structure of the machine to give it the necessary rigidity, and, second, such a weight must be provided on the driving means that sufficient adhesion is present under all ordinary conditions of working to transmit the maximum power of the engine through the lowest gear ratio without slip occurring between the ground surface and the surface of the driving means.

There is one other point of great importance that must also be remembered, and this is that the application of the weight of the machine to the surface must be carried out in such a manner that the intensity of local stress at the point of contact is reduced as far as possible. This statement also infers that the area of loading should be as large as possible. A round wheel theoretically makes line contact with a hard surface; in practice this line assimilates width and becomes an elongated rectangle. As the diameter of the wheel increases, so does the width of the rectangle, which fact has led builders of wheels to increase the diameter of the wheel in order to reduce the intensity of loading at the point of contact with the road.

Advantages in Caterpillar Principle

Incidentally a wheel of larger diameter with its reduced intensity of loading causes a smaller depression upon a road as it rolls along, and is therefore easier to propel. Adding width to the wheel is another step in the general endeavor of the manufacturer of a round wheel to surmount many of the difficulties which are attendant upon the use of a wheeled tractor where the road surface is soft or rough. Wheels became of such colossal dimensions that the very largest machines were impracticable upon many of the roads and bridges provided for the accommodation of the ordinary traffic of the country, and other means were therefore sought to relieve the situation.

For many years past various firms engaged in the manufacture of agricultural appliances and engines for the propulsion of the same have been engaged in experimental work with a view to the development of some form of support for a heavy, self-propelled vehicle. Emulating the means provided by nature to the elephant, large sums of money were expended upon walking machines of the "pedrail" type. Theoretically such a system embodies many desirable features, as the loaded surface is directly applied to the road and its plane is parallel to the road the whole time. More than one loaded surface can be in contact with the road simultaneously and the area of contact can be anything

within reasonable limits. In such an appliance, the mechanical contrivance corresponding to the ankle was of some complexity and the whole system has been recently abandoned in favor of the continuous track system.

The necessity for some means of cultivating large tracts of unbroken prairie land in the western States of America was one of the reasons for the development of the caterpillar tractor. In such country, the ground is rough and covered with brushwood, and other serious obstacles to cultivation, requiring a considerable amount of power for their removal.

It is obvious that in the first place trees should be uprooted bodily and this work can be done by the direct pull of the caterpillar. This pulling power is obtained by reason of the high coefficient of traction of the caterpillar tread upon the ground, which is scarcely affected by the uneven contour. We know from experience that were a round wheel engine to attempt work of this nature, the result would be that the wheels would dig channels in the ground and the machine would bury itself up to its rear axle.

In Reclamation Work

Reclamation projects have almost entirely depended upon caterpillar power for their attainment and in the delta land of California, for example, no other machine but the caterpillar can be used on certain tracts. In these districts there are large areas of peat formation which have at one time been below the level of the water. This land has a very soft upper surface, so soft in fact that the foot sinks down in walking over it. There is not only this softness of the surface to contend with, but the whole ground is seared with fissures, so great in some instances that a man or a sheep can sink readily into one and disappear.

Even after some years of cultivation and continuous packing by the passing over the surface of agricultural implements and tractors, these fissures are still present to a considerable extent and it is impossible for horses to operate. True it is that some round wheel engines are used on parts of this land and also some round wheel harvesting machines, but in such cases the wheels are of colossal dimensions.

The large gas tractor has developed very slowly in Europe. The cost of a volatile liquid fuel there almost precludes it from industrial application on a large scale, and it is only in countries where distillates from petroleum can be obtained at a comparatively low price that large internal combustion engines can prove attractive in competition with a coal-fired steam engine on the point of cost. We therefore find that it is in America that the large internal combustion power unit of the track-laying type has been the most fully developed. In this country we find a considerable number of firms making track-laying machines, all of which are very closely allied in general design, and it must therefore be assumed that the type of track and the method of rolling thereon have been proved to be the most satisfactory of the undoubtedly large number of experimental designs that have been tried out. From an impartial standpoint, the main characteristic of the track-laying machine is its apparent crudity as compared with the motor truck; a finely developed mechanical production, which is a vehicle of almost similar requirements. This characteristic is probably due to the fact that track-laying machines are generally made by firms who are engaged in the construction of agricultural implements and who have not been required to produce apparatus having that fine finish which is so necessary in automobile practice.

Special Abilities of the Caterpillar

In spite of this apparent crudity, there is no doubt that the best type of track-layer, such as the caterpillar, gives extraordinarily good service, and, in a word, whatever may be doubtful about it, it certainly does work easily, which no other type of machine can attempt. This shows that the caterpillar is in a class by itself, and it undoubtedly must be built to meet many extraordinary conditions in working, of which the layman is unaware.

The caterpillar fully comprises the chief advantages of a tractor for farm work from the point of view of the operator, which are:

Ability to do heavy work rapidly, thus covering the desired acreage within the proper season.

The saving of manual labor.

Upper left—Caterpillar tractor uprooting tree by direct pull. Center—Caterpillar harvesting machine working in barley where the softness of the ground renders it impossible to use a round wheel. Right—Steam tractor, showing enormous wheels required. Lower left—Caterpillar tractor pumping for irrigation at Lovelock, Neb. Lower right—Use of the caterpillar in harvesting on a side hill

Upper left—Caterpillar tractor hauling fifty-two cords of timber at Fairbanks, Alaska. Right—Caterpillar used in logging. Lower left —Hauling hay in California. Right—Use in hauling equipment and material for a water development in Los Angeles, Cal.

The ability to plow to a good depth, especially in hot weather, but it does not suffer from the great disadvantage of other tractors, namely, the packing of the soil when damp.

There is one other disadvantage cited against tractors for farm work and that is the difficulty of efficient operation, but in the caterpillar this is reduced to a minimum, and particularly in those types which can be turned around practically in their own length. Like any other machine, and particularly of the internal combustion type, where the power of the engine is limited, it is particularly necessary in choosing the size of a caterpillar that three factors be borne in mind:

1—A machine that will produce enough power to do the work in the best possible way.

2—That will produce enough power to do all the work at the time when it should be done.

3—With enough power to do the work in the right way and at the right time, and when pulling a normal load and not an overload.

Need for Data on Required Power

So far as agricultural requirements are concerned, it is almost impossible to obtain definite data of the drawbar pull necessary for the various appliances, in different soils and working at different depths in the case of plows. Certain firms are experimenting at the present time with the object of determining some of the conditions to be fulfilled by an agricultural tractor as regards drawbar pull. The purchaser, however, specifies his requirements and the number of plows he requires to operate, and the following table, obtained from the experiences of owners in Illinois, will give some idea as to the size of the tractor required for various sized areas under cultivation:

Farms having 200 acres or less of crops—a 3-plow tractor.

Farms having from 200 to 300 acres—a 4-plow tractor.

Farms having from 300 to 450 acres—a 4-plow or larger.

For 450 to 700 acres of crops, the 4-plow is given slight preference, although the 5- and 8-plow sizes are recommended by 22 per cent of owners.

A farm of 140 acres is the smallest upon which the smallest size tractor in common use may be expected to prove profitable.

Fuel Consumption 2½ Gal. per Mile

It must not be supposed that the purchase of a caterpillar will lower the working cost of any farm, but its purchase must be justified by increased returns. No matter what be the size of the machine, a general average may be taken of fuel consumption at the rate of 2½ gal. of gasoline and 1/5th of a gallon of lubricating oil per one acre of ground plowed 7 in. deep. This figure will, of course, vary with the working conditions and with the skill of the operator, as obviously the fuel consumption will be approximately proportional to the load on the engine when a good carbureter is used. This is indicated by the following general figures for the fuel consumption of a 75 hp. caterpillar engine, which at full load has a rate of fuel consumption of 0.63 to 0.66 lb. per hour; at half load 0.75 to 0.80 lb. per b.h.p. hour; and at quarter load 0.9 to 1.1 lb. per b.h.p. hour.

The caterpillar, like other apparatus of a somewhat novel type, has of necessity some drawback, and in this instance it is that of loss of power in the transmission system and in the tracks. In the case of the largest caterpillars, this total loss is of the order of 42 per cent on the direct gear and 48 per cent to 53 per cent on the high gear. This total loss is not entirely frictional, but it includes possibly as much as 10 per cent of the b.h.p. of the engine, which is to be held in reserve to overcome sudden emergencies. If the drawbar is too heavily loaded and a rough spot is met on the road there is otherwise no means of meeting the sudden demand for an increase of power, as the engine is controlled by a governor of a somewhat slow acting type. As an indication of the tractive power of a 75 hp. caterpillar, the following figures may be of interest:

Drawbar Pull Over 8000 lb.

With the direct gear in operation in the transmission at a speed of 2.01 m.p.h., the drawbar pull was 8500 lb., giving a horsepower on the drawbar of 45.9. When the speed was increased to 2.07 m.p.h. by running the engine slightly faster, the drawbar pull was reduced to 8200 lb. and the drawbar horsepower to 45.3. The road speed of the caterpillar is limited to about 3½ m.p.h., principally by reason of frictional loss as the speed increases above this figure, and tests have shown that, whereas at a speed of 2 m.p.h. the frictional loss amounts to 13 hp., this increases to approximately 20 hp. at 3 m.p.h., and 27 hp. at 3½ m.p.h. For agricultural purposes a direct geared machine at 2 m.p.h. is working under the most advantageous conditions, but for road haulage it is convenient to gear up on the indirect.

The 60-hp. caterpillar is a similar type to the 75-hp., but having an engine of half an inch smaller bore gives a draw-

bar horsepower of 38 at a road speed of 2.2 m.p.h., producing a mean pull of 6500 lb. An equal mean pull is obtained by the 45-hp. machine when running at a speed of 1.47 m.p.h., and under these conditions the drawbar horsepower is 25.6. With the same machine running in the direct high gear at a speed of 2.1 m.p.h., the drawbar horsepower is 28 and the pull 5000 lb. These average figures for drawbar pull are between the limits of about 1000 lb. on either side, as in actual working there is considerable vibration and variation due to the loading.

Let us for a moment look at the work which such a machine is called upon to do in actual usage, and consider why caterpillar traction is not only advisable but practically imperative when full return is required from an initial capital outlay:

Effect of Deep Plow on Harvest

Definite experiments have shown that by increasing the depth of plowing from 3 in., which is common practice, to 7 in., the yield on a 3 years' average increased to the extent of 6.33 bushels per acre. Experiments made by the University of Wisconsin show that to double the depth of plowing requires an increase of 70 per cent in power.

President J. H. Worst of the North Dakota College of Agriculture says: "It requires approximately $7 per acre to grow a crop. By adding an additional dollar's worth of labor to each acre there is little question but that the average profit will be doubled. In other words, as much profit should be realized from one additional dollar's worth of labor as is now realized from $7 worth of unavoidable labor and investment."

It might seem that the investment in a tractor only working for less than one-third of the total number of days in the year, might be unprofitable. Let us see:

Taking a four-plow machine which works on an average of 60 days per annum, the estimated average life of this machine is 510 days, while with a larger tractor, say a six-plow machine, working 70 days per annum, its average life is 735 days. These figures will appear low at the first glance, but it must be remembered that when horses are employed they are only occupied about 100 days per annum doing farm work, so that when both horses and tractor are used, even though the number of horses is reduced, the tractor will not have employment for so many days per annum as did the horses.

A 60-hp. caterpillar purchased in 1912, doing farm work, in 1914 harvested 3200 acres, in 1915 2200 acres, also plowing for beets 12 to 14 in. deep in grain stubble that had never been plowed before, and pulling four 14-in. Killifer plows. The price paid for this plowing is $4 per acre, and this particular machine has been in almost continuous use for 45 months and has plowed 9000 acres, disked 12,000 and harvested 10,000, besides doing miscellaneous work. During its life it must have traveled at least 18,000 miles.

Herewith are illustrated various types of caterpillars performing this class of work and, generalizing on the impression to be gained from the inspection, one cannot help being impressed by the width of the strip which is under cultivation behind the caterpillar. Naturally this width must vary in accordance with the implement hauled and with the nature of the ground in which it is working and as this may present such a number of different conditions, it is quite impossible to give any definite figures with regard to the number of plows, for example, that any type of caterpillar will haul.

Disadvantages of Round Wheels

It may be contended that a round wheel machine can do similar work and this is quite true in a measure and under certain conditions. The contention, however, is that a round wheel engine, by reason of its intensity of loading, leaves wheel tracks which show up particularly when harrowing as the harrows do not obliterate these tracks. The result is that the grain will show up in uneven rows at harvest time and such grain as has been planted in the tracks will not mature to the same extent as the rest of the field. The intensity of loading on the caterpillar track does not exceed 7 lb. per sq. in. and can be reduced to half that pressure if necessary by fitting wider tracks.

(To be concluded)

Upper left—Caterpillar tractor hauling an eight-bottom plow. Note the deep furrows. Right—Another application with a gang plow. Lower left—Caterpillar tractor hauling a disk plow. Right—Use in pulverizing and disking ground

Martin Aviation Engine Unique Design

Special Cylinder Construction and Very Accurate Workmanship Give Light Weight—Design Is Very Compact

THAT the aviation engine has now to be a very different kind of product from the conventional automobile motor, even of the highest quality, is an accepted fact. To obtain the ability to stand up to as severe stresses as a racing car engine and to hold up for many hours of continuous service a class of workmanship is required which would be absurd in an automobile engine. Cost, at least as long as governments are the principal buyers, is of little moment.

Of all the special requirements of the aviation engine that of ability to stand up is the most difficult to meet, and it can only be met, in conjunction with light weight per horsepower, by the use of exceptionally strong materials. One of the most troublesome parts of an engine in which to combine strength and lightness is the cylinder, as this has to do many things besides sustaining the combustion pressure, and the cylinder construction is quite one of the most striking features of the Martin engine. This motor is made by the Griffith Machine Works, Los Angeles, Cal., and is designed by Glen H. Martin in conjunction with E. C. Griffith and Caleb Bragg. It is an eight-cylinder V job with the cylinders at 90 deg., using the forked type of connecting-rod assembly.

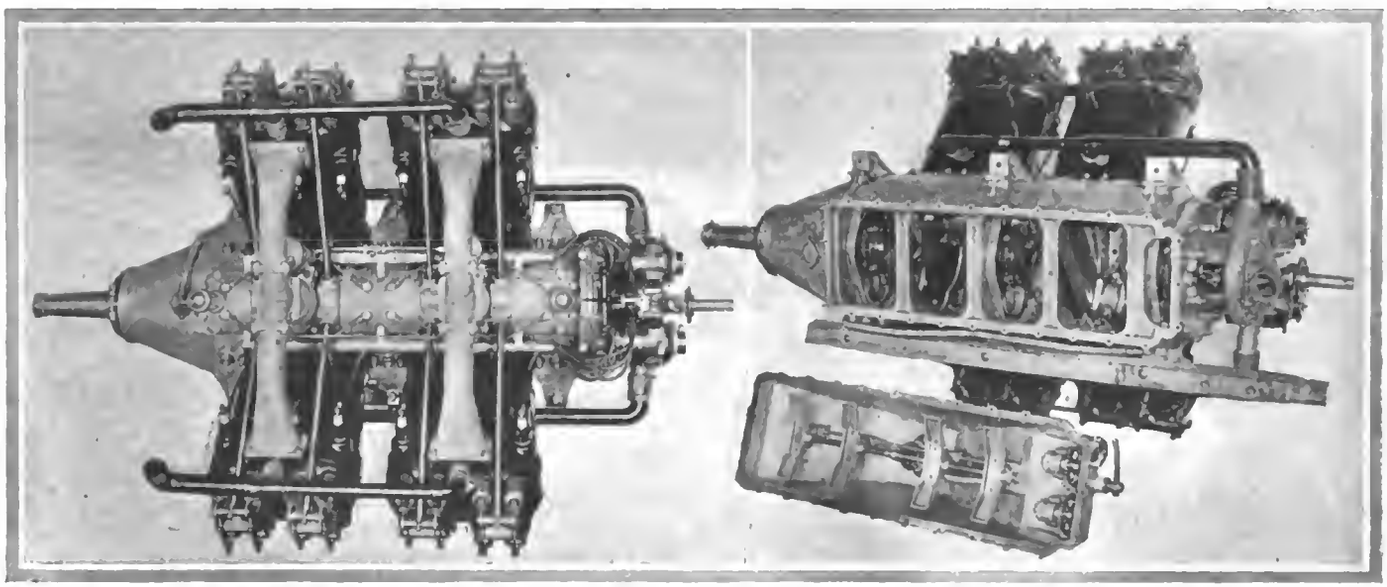
Built-up Steel Cylinders

However, to return to the cylinders, these are all steel and something like the Mercedes type. That is there are several parts of steel welded together. A difference occurs in the extent of this welding, for the Martin engine cylinder is built up from more pieces. The cylinder wall and the head, where the valves seat, are both machined all over to an even thickness, there is no more metal just back of the valve seats than anywhere else, thus the cooling is as nearly perfect as it could be made. Next, the jackets are stamped from a quite large number of bits of sheet steel the junctions being welded. The work is so neat that the pairs, into which the cylinders are formed by the jackets, look like very high grade castings, and the economy of metal is shown by the weight of the cylinder being only 24 lb., despite a bore of 4⅞ in. and stroke of 7 in.

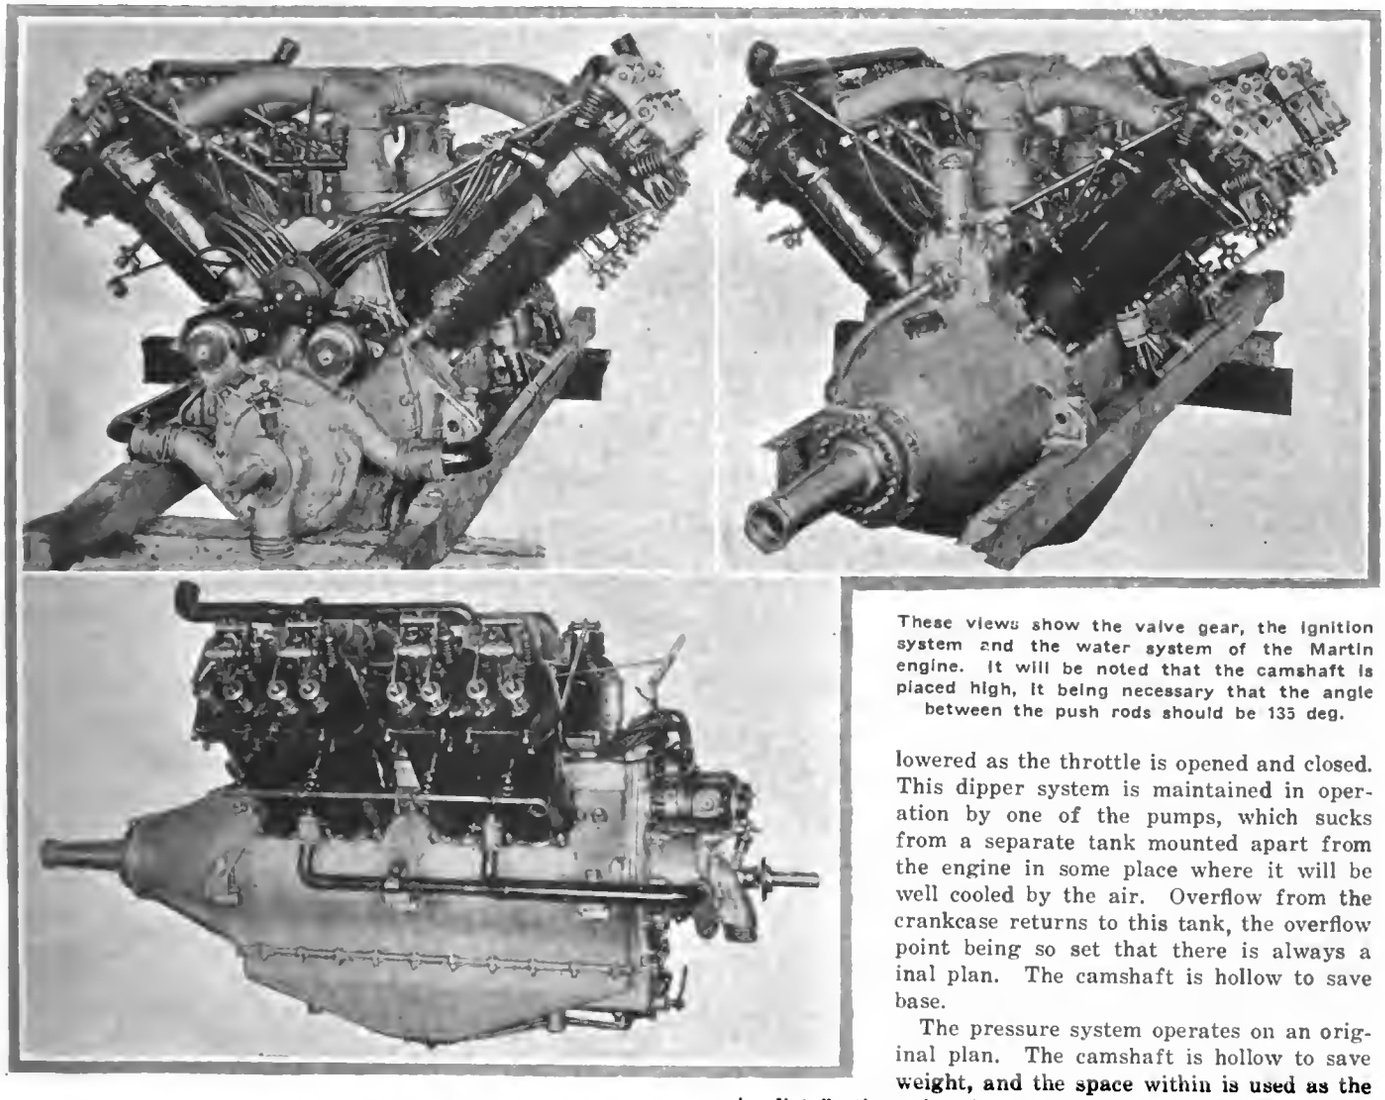
Push and Pull Valve Action

The valve operation is unusual as can be seen from the illustrations. Double ended rockers swing on pivots placed above the cylinders and linked to the camshaft by a single steel tube. The cams are duplex and the tappet is of stirrup form, so that the camshaft first pulls the operating rod, so opening the two intake valves, and then the second cam pushes the rod upward, thereby depressing the pair of exhaust valves. This design calls for very careful workmanship, but granted this, it eliminates a number of parts and so saves weight. It will be noticed that the double cam takes care of all the inertia forces in the push rod and tappet piece, all that the valve springs have to do is to close the valves themselves.

Using one push rod for both valves and one pair of cams for opposite cylinders necessitates a high mounting for the camshaft. Since the pistons are operating with 90 deg. between each two of a V pair, and since the camshaft runs at half the crankshaft speed, it moves through only 45 deg., while the crank is covering 90 deg. If the engine is running clockwise the right hand piston will be going up on the exhaust stroke when the left hand piston is at the top of the compression stroke. At this moment the left hand intake valve will have been closed for 180 deg. of crankshaft or 90 deg. of camshaft movement and the right hand intake valve will have to open at the end of the next 90 deg. of crankshaft or 45 deg. of camshaft movement. Adding 90 to 45 it follows that the angle between the push rods will have to be 135 deg.



Plan and base views of Martin aviation engine, showing the tubular valve operating rods, the dip troughs which move in conjunction with the carbureter throttles and the great rigidity of the crankcase construction



These views show the valve gear, the ignition system and the water system of the Martin engine. It will be noted that the camshaft is placed high, it being necessary that the angle between the push rods should be 135 deg.

The rigidity of the crankcase can be appreciated from the view taken with the oil container removed. As can he seen, it is wehbed strongly, the crankshaft and all the bearings being introduced from the rear end. Stiffness in the case is especially necessary in aircraft motors, because of the considerahle twisting stresses arising from the propeller. If there is too little rigidity in the "nose" of the crankcase, and insufficient stiffness behind the nose in the body of the engine, the propeller can sometimes set up a weave which will result in a broken crankshaft. As shedding a little light on this matter it may be mentioned that unexpected trouhle with the thrust bearings hack of the propeller has been quite usual in aircraft engines, and investigation has shown the gyroscopic action of the propeller can, under some circumstances of flight, set up stresses of remarkable magnitude.

The Martin engine does not use a geared head, but mounts the propeller on a shaft which is an extension of the crankshaft to which it is bolted. This means that the motor is not intended to run at a very high speed as speeds go in automobile work. On a government test at Washington the peak of the power curve appeared at 1326 r.p.m. when the power developed was 183 b.hp. this corresponding to a piston speed of 1500 ft. per minute in round figures. The hrake mean effective pressure for the 183 hp. is 116 lh. per square inch, a very high value.

Effective lubrication when operating at all angles in the air, has been another difficulty in aviation engine construction. In the Martin motor there are two oil pumps, one caring for a pressure system and the other for splash. Under each connecting-rod there is a dip trough which is raised and lowered as the throttle is opened and closed. This dipper system is maintained in operation by one of the pumps, which sucks from a separate tank mounted apart from the engine in some place where it will be well cooled by the air. Overflow from the crankcase returns to this tank, the overflow point being so set that there is always a inal plan. The camshaft is hollow to save base.

The pressure system operates on an original plan. The camshaft is hollow to save weight, and the space within is used as the main distributing pipe for the pressure oil. The pump delivers oil to one end of the camshaft and holes, registering with passages in the crankcase, carry the oil to the main crankshaft bearings and thence to the crankpins. Smaller holes give oil to the cylinders direct, and to the cams and tappet mechanism. On this oil system there is a throttle, connected to the carhureter control, so that both pressure oil and splash oil are fed in proportion to the demands.

Two Magnetos Used

On the rear end of the camshaft there is a special high-tension distributer which is duplex, sixteen wires coming from it to the two independent sets of spark plugs. On either side of this distributer is a magneto, driven by gearing at twice crankshaft speed, and either machine will run the engine satisfactorily, though an increase in power is shown on the dynamometer when hoth are operating together.

The water pump, which is a double-discharge type, is mounted on the end of the crankshaft just beneath the magnetos and gives a direct supply to each cylinder pair through pipes connecting at the lowest points in the jackets. Two carbureters are employed, mounted in the V.

It will be noticed that aluminum alloy is used in this engine to no greater extent than in a conventional automohile motor. The crankcase, heing so rigid in form is of thin section and the steel cylinders are claimed to be lighter than if of aluminum. Pistons are aluminum alloy, of course, and are strongly rihhed beneath the heads. The motor has undergone severe tests for the United States navy, and also at the Automohile Cluh laboratory, with conspicuous success.

The Rostrum

Building Over a Regal Into a Raceabout

EDITOR THE AUTOMOBILE:—I have a 1912 Regal model T underslung which I would like to change over into a raceabout. The first question is, what gear ratio shall I put in so that I can travel from 60 to 70 m.p.h. on the level? Where can I get these gears; that is, the bevel gear and the drive pinion? I think by changing these and not disturbing the transmission I can get the speed I wish.

2—Please tell me how I can lower the steering wheel post.

3—What firms manufacture bucket seats?

4—Where can I obtain a large capacity oval gasoline tank and an oval oil tank for a rear deck?

5—Will it be possible to have enough gravity without a vacuum system on it?

6—Kindly suggest a body design with seat and tanks on it that would be suitable for this model.

Barre, Vt. A. M. F.

—If properly tuned up one of these cars should be able to do better than 60 m.p.h. with a 3 to 1 ratio. These cannot be furnished by the Regal company, but if you will take the matter up with the Weston Mott Co., Flint, Mich., the builder of these axles, they may be able to furnish them.

2—The only way that this can be done is to remount the clamp which is bolted over the tubular motor sub-frame. Any good repairman can do this for you or tell you how to do it if you show him what you wish done.

3—Any large supply dealer can furnish you bucket seats and tank. If you cannot buy these directly from your dealer, they may be ordered from any of the mail order concerns.

4—Answered under No. 3.

5—By keeping the carbureter low and the tank high, you can probably get a gravity feed.

6—The so-called Mercer type body ought to be satisfactory, with the tilted bucket seats, then the gasoline tank with the oil tank on the platform behind.

Wiring Diagram of 1914 Cadillac

Editor THE AUTOMOBILE:—Kindly publish wiring diagram of a 1914 Cadillac, omitting the following devices: dry battery, ignition system, circuit breakers, horn and carbureter heater. Where should an ammeter be installed?

Mandan, N. D. J. G. B.

—The wiring diagram you ask for is shown in Fig. 1.

The connections for installing an ammeter are illustrated at the upper right of the diagram, Fig. 1. You must, of course, be careful that the ammeter is connected the right way around for the direction of current flow.

Crankshaft Speed and Engine Efficiency

Editor THE AUTOMOBILE:—What seems to be the best crankshaft speed for a four or six-cylinder engine to peak at from the viewpoint of service, reliability, consistency and general performance? I refer to a touring car or roadster weighing between 2300 and 3300 lb., preferably from 2500 to 2700 lb., fully equipped.

2—What is the balance between piston displacement and crankshaft speed? By this I mean that a 275-cu. in. engine will permit of a higher crankshaft speed than a 450 or 600-cu. in. engine. The point I wish to know is, what is the best balance to make between piston displacement and crankshaft speed? Give piston displacement and crankshaft speed

3—Which engine will show the longer life, both being correctly handled, a 250 to 300-in. engine of the small bore, long stroke class having large valves and peaking at say 2400 to 2500 r.p.m., or a 350 to 425 in. engine which peaks at from 1700 to 1800 r.p.m.? I refer to four-cylinder engines mainly.

4—Kindly advise me why a sixteen-valve racing type engine identically like the Wisconsin, Stutz, or the 274-in. Peugeot but made to peak at from 2400 to 2500 r.p.m. would not be a decided success in the touring car? Couldn't a sixteen-valve, four-cylinder engine be made as easily and as cheaply as a sixteen-valve, V-type eight-cylinder engine?

5—Why, in a four-cylinder engine, would not cylinder dimensions of 3 2/3 by 6 2/3 be far preferable in a touring car than say 4¼ by 4⅞ for approximately the same displacement? Peugeot touring cars have cylinder dimensions very near identical to their racers and all modern racing cars have the small bore and long stroke not far from 3.7 by 6.6, and these cars stand much more severe treatment than touring cars. I would like to get actual existing conditions regarding this.

6—Kindly give me the average proportion of power increase as the compression is increased in the engine? For example: how much more power will a 3½ by 5 engine having 85 lb. compression have over one having 60 lb. compression at the same crankshaft speed.

7—In a six-cylinder engine does the use of two carbureters prevent dividing the gas stream by two intake valves being open at once as in the case when only one carbureter is used?

Beemer, Neb. G. S.

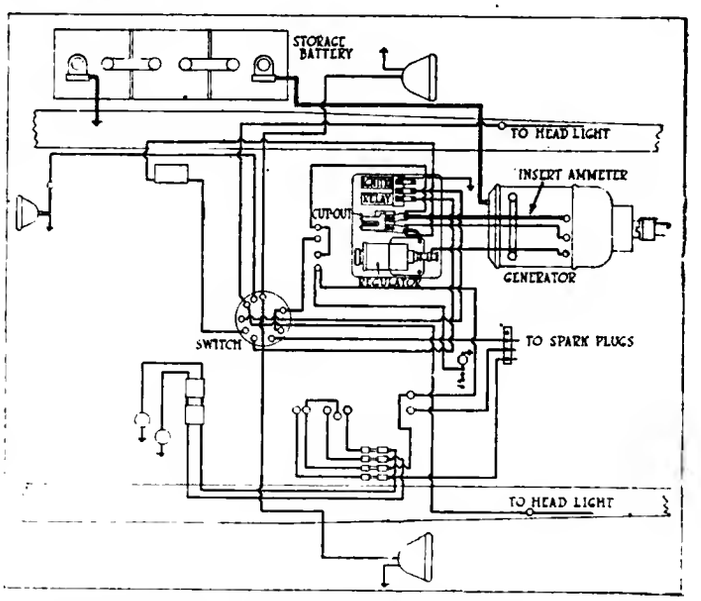


Fig. 1—Wiring diagram of 1914 Cadillac, showing the connections for installing an ammeter. In installing this instrument care must be taken to see that it is done correctly with respect to the direction of current flow

—Between 2000 and 2500.

2—You can employ practically the same piston speed for any bore of automobile engine between 2½ and 4 in., which covers nearly all the sizes in use to-day. Crankshaft speed bears no relation to piston displacement but simply to stroke. A good engine should deliver a little more than its formula rating at a piston speed of 1000 ft. per min. It should be able to run at a piston speed of 2000 ft. per min. and it is not unusual to find the peak of a horsepower curve just about coincident with a piston speed of 2000 ft. per min. It is only when the stroke is 6 in. that this means a crankshaft speed of 2000 r.p.m.

3—There should be no difference.

4—The advantage of a very large opening given by sixteen valves does not begin to be apparent until well above 1500 ft. per min. piston speed. The sixteen-valve four, owing to the elaborate nature of the lifter mechanism, will probably be more expensive than an ordinary eight.

5—The reason that the most highly developed engines used in Europe are a small bore and long stroke is that taxation and racing rules have forced the development of this type. The large-bore short-stroke engine has never been highly developed. The general opinion of engineers in Europe and America is that the best ratio of stroke to bore lies between 1.3 and 1.6.

6—This subject has been investigated by many people, but it is so complicated that no reliable formula has ever been worked out. The following table shows a series of values of mean effective pressure obtained with varying compression under similar conditions, compression is one series and M. E. P. is the other series.

Compression	Mean Effective Pressure
222	86
175	92
124	82
87	72

7—This is the theory for fitting two carbureters.

Information on 1914 McLaughlin-Buick

Editor THE AUTOMOBILE:—Kindly give power and torque curve of 1914 four-cylinder 35-hp. McLaughlin-Buick car.

2—What is the ratio of the different gears?

3—What speed can this car travel when in good order?

4—How far apart, in thousandths of an inch should the platinum points of the Delco timer be?

5—Please give way to adjust the Marvel carbureter which is attached to that car.

6—What is the right clearance between the valves and the valve tappets?

7—Would you advise an extra air inlet on that car?

Montreal, Que. A. L. H.

—The curves which you ask for are not obtainable.

2—The gear ratios are: First, 13.5 to 1; second, 6 to 1; third, 4 to 1; and Reverse, 17 to 1.

3—The car should be capable of about 50 m.p.h.

4—Breaker points of the Delco distributer should be set 0.0018 in. apart when opened.

5—There are two main adjustments of the needle valve *A* which controls the size of the needle, and an air adjustment *B* which controls the air. After the engine has started close the throttle to moderate speed, which means nearly closed. At this point close gasoline needle *A* a very little at a time until motor runs smoothly, allowing the engine to run until thoroughly warmed up before making final adjustments. The next step is to get proper adjustment of the air valve. To accomplish this, air valve adjusting screw *B* should be turned to the left to back out and release the air spring about one-eighth of a turn at a time until the engine begins to slow down. This indicates that the air valve spring is now a little too loose, whereupon it should again be tightened a little by turning to the right one-eighth of a turn at a time until the engine runs smoothly. Next advance the spark one-

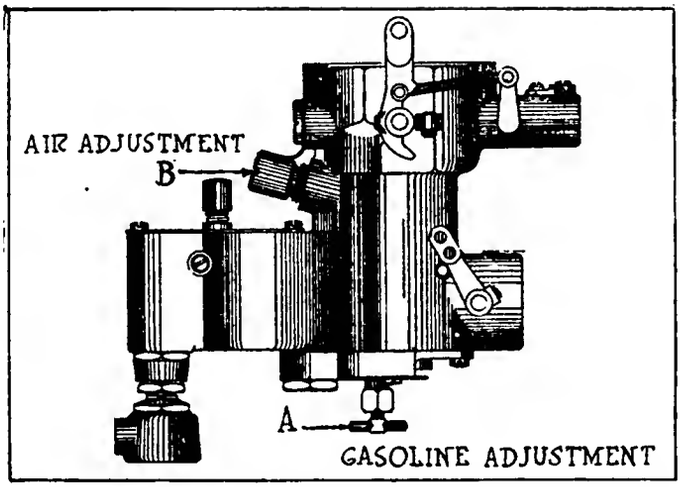

Fig. 2—Marvel carbureter used on the 1914 four-cylinder 35-hp. McLaughlin-Buick, showing points for adjusting the gasoline and air intakes

third of its entire travel. Now open the throttle quickly and as far as possible; upon doing this the motor should speed up promptly and quickly. If it hesitates, or popping back is heard a little more gas should be released at the needle valve *A* by turning to the left a very little at a time, and it may also be necessary to tighten the air screw a little more, but this should not be done unless absolutely needed. Wait for the engine to settle and again open the throttle quickly as before. Repeat these trials until the proper adjustment is obtained, the object being to have just enough gas to allow the engine to pick up promptly and smoothly when the throttle is suddenly opened, the spark, as mentioned before, being at about one-third of its advance or travel. The highest economy of fuel will be obtained by adjusting with the air screw *B* released to the left, and the gas valve *A* closed to the right, as nearly as possible to obtain the desired results.

6—When valve tappets are properly adjusted there should be a clearance of 0.005 in. between valve stems and rocker arms.

7—We would not advise installing an auxiliary air inlet except for racing purposes.

Make and Break Both Positive

(*Continued from page* 180)

and thus the cam mechanically makes and immediately afterward mechanically breaks the circuit. Since both the make and break are made by the cam, both are equally positive, and the contact can neither fail to make nor fail to break and the strength of the springs does not affect the action.

Owing to the short duration of the contact, current consumption is small and the positive action is claimed to permit the distributer to operate perfectly at speeds in excess of the highest engine demands.

The whole distributing outfit is made up into single units 6 in. high by 3½ in. diameter. It includes the coil and condenser in symmetrical arrangement, so that the only external wire is a single lead to the battery in addition, of course, to the high tension leads to the spark plugs. The latter are stationary since the breaker box is moved independently of the cables. The distributer coil and condenser may be conveniently removed in one piece, uncovering the interrupter mechanism for adjustment and at the same time showing up a set of complete printed instructions for operating the same. The manufacturers are at present prepared to furnish this igniter for four, six or eight-cylinder engines, and they will shortly be in a position to supply a twelve-cylinder distributer.

The FORVM

REVOLVING MOTION OF WHEEL AROUND STATIONARY AXIS AND ITS ROLLING MOTION ON GROUND IN RELATION TO MOVING AXIS COMPARED—TWO-CYCLE POSSIBILITIES

Motion Analysis of Rolling Automobile Wheel

By C. V.

THE analysis of the rolling motion of a wheel brings forth several interesting facts. Taking an automobile wheel as example, particularly instructive is the comparison between the revolving motion of the wheel around a stationary axis and its rolling motion on the ground, in relation with a moving axis.

Let us take a 36-in. automobile wheel rolling in a straight line, in a vertical plane, upon a smooth horizontal plane or ground. Let us suppose that the tire is sufficiently inflated so the total diameter d of the wheel remains constant. Referring to the diagrams in Fig. 1, point 0, the wheel center, is also its axis. Starting from the point A, where the ground line AB is tangent with the diameter AE, let us give the wheel one complete revolution, that is, rolling the wheel till the point A again meets the ground at B. The axis 0 will have traveled a distance $00' = AB = d\pi = 3 \times 3.1416 = 9.4248$ ft., while the point A will have described, in a vertical plane, in the same time, a trajectory resembling the upper half of an irregular ellipse whose small diameter is $2d = 2CD$ and large diameter equal to AB and also to $d\pi$.

Any point x, below center 0 will describe an irregular curve similar to xy (dotted curve) on line xy, the curve portion below the axis line $00'$ will be sharper than the one above $00'$; in fact, both curves will gradually flatten out for every point as we get nearer to 0, where the dotted line will finally assume the shape of the straight line $00'$ which coincides with the line of axis travel. The sharpness of the lower curve of the dotted line xy will increase as we get nearer to point A, where, figuratively speaking, this lower curve, growing gradually smaller, will be eliminated and become a dead stop or dead center A, which, if the wheel is rolling according to the previously stated conditions, will coincide at equidistant points along the ground line AB.

Let us find the length of the elliptical line ACB. The simple formula given below allows us to figure with a fair degree of accuracy the perimeter p of an ellipse, viz:

$$= d\sqrt{\frac{D'^2 + d'^2}{2} - \left[\frac{D' - d'}{8.8}\right]^2},$$

Where D' = Large diameter
d' = Small diameter.

Substituting, $D' = 9.42$ ft., and $d' = 6$ ft., we find $\frac{1}{2}p = 12.26$ ft., approximately.

In one revolution, with our 36-in. wheel, the point A will then have traveled, in the vertical plane of the wheel, a distance $ACB = 12.26$ ft., giving us a ratio, or constant of $12.26 :: 9.42 = 1.3$ (approximately). Therefore, in the case of a racing car traveling 100 miles in 1 hr., the point A will have described, in the same time, a number of half elliptical motions, the total length of which will reach 130 miles.

Since the curved line ACB belongs to an ellipse and supposing that the rate of speed of the axis $00'$ is constant, it results that the rate of speed of the point A, along the plane ACB, is not uniform, even if the curve AC is symetric to the curve CB; if we divide the parallelogram $AEFB$ in four equal parts or four equal parallelograms, the time necessary for one complete revolution of the wheel is also graphically divided into four equal parts or periods.

A glance at the parallelograms $AEIG$ and $GICD$ easily shows that the curve AH is longer than HC. A further study of the elliptical line ACB also shows that, this curve being at its sharpest near the dead stops or dead centers A and B, the point A will reach its maximum speed when approaching or leaving the ground. Couple this fact with the inertia-like effect occurring around the dead center A, ad also the destructive action of the tractive force applied at A in the case of the driving wheel, and one will easily understand the incredible amount of punishment that an automobile tire is subjected to at racing speeds.

On each revolution of the rolling wheel, the point A must come to a full stop, at point A which coincides with the ground, in order that the wheel may exercise its tractive power under correct conditions. These points of coincidence must be equidistant in accordance with the value $d\pi$. Hence, if the ratio between the length of the curved line ACB and straight line AB is not $\frac{1.3}{1}$, evidently the wheel is not running properly: if, during the time required for the axis 0 to travel the distance $00'$, the point A happens to travel, in the wheel plane, a distance longer than $1.3 \times AB$ (or $1.3\ d\pi$), the wheel is *slipping;* if the point A travels a shorter distance, in the same period of time as above, than $1.3 \times AB$, the wheel is *skidding.*

If the front wheels of a car are out of line, slipping must necessarily occur since point A travels in this case along a helical plane, in relation to place ACB. Then A's travel is longer than $1.3\ d\pi$; same thing happens in the case of a wobbling wheel (through bent axle or rim), since point A's travel cannot remain within the plane ACB. In the case of a differential-less axle turning a corner, point A's travel will be either $> 1.3\ d\pi$ or $< 1.3\ d\pi$, which means *slipping* or *skidding* for *either* wheel. All the above cases will cause friction with the ground, loss of power and abnormal wear on tires.

When driving around a curve, the relation $1.3\ d\pi$ remains true, but the centrifugal force will cause extra wear on the tires on account of the side thrust unless the curve happens to be banked in proportion to the speed of the car. It must be also remembered that under ordinary conditions,

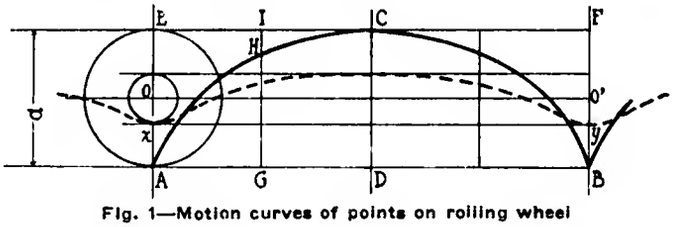

Fig. 1—Motion curves of points on rolling wheel

the wear on the front tires will be smaller than on the rear ones because the former are only subjected to a rolling action while the latter must stand also a propelling and braking action; careless use of brakes is particularly destructive to tires.

Driving through sand or soft dirt gives the same impression as if the brakes were applied to all the wheels; these must make their own tracks as it were, before the car may make any headway. It is very dangerous while driving fast on a smooth road, to drive suddenly on the soft dirt (if there is any on either side of the road), as the steering will be seriously interfered with by the wheel striking the dirt.

In actual practice, we are far from the theoretical conditions of a perfectly round tire meeting a perfectly smooth ground at only one point of contact. A pneumatic tire flattens down to a certain extent, offering an oval surface the size of which is in direct proportion to the weight applied to the wheel and in inverse proportion to the inflation of the tire and the non-resiliency of its material. Among the most important factors upon which depend the tractive possibilities of a given tire are the weight acting on the wheel, the condition of the ground, the design of the tread and the inflation pressure.

Two-Cycle Engine Development Neglected—Its Possibilities

By E. W. Roberts, M. E.

I HAVE noted with considerable interest the letters in the Forum for June 8 on the subject of the two-cycle engine. I have had some 14 years' practical experience with this type, having designed over fifty and built them by the thousand. My experience covers their use in automobiles, motor boats and aeroplanes. In addition I have done a great deal of work in the capacity of consulting engineer in helping others perfect engines of this type.

My experience, which is confirmed in some measure by the opinions expressed in the majority of the letters referred to, is that the average engineer is very much inclined to jump at conclusions with regard to the two-cycle. Notions get abroad that are taken as truths, and many writers state them as a matter of fact. Take the one matter of the crankcase acting as a scavenging pump, and its effect on the lubrication. The notion is abroad that it will cut the oil and interfere with the lubrication. This notion has absolutely no foundation in fact. It is easily shown to be a fallacy by the fact that the very best way to lubricate a two-cycle of this type is by mixing the oil with the gasoline. I have tried every other possible method, and found that this one not only gave me the best results, but was economical of oil. There is no more fool-proof oiling system imaginable.

Limitations as to Speed

Another false notion is the two-cycle's limitations as to speed. If the same amount of intelligence is put into the design of a high-speed two-cycle as is applied to the four-cycle, equally good results may be obtained. The same rules apply as to intake and exhaust areas, weight of reciprocating parts, etc., as in the four-cycle type, with this to be kept in mind. The crank angle during which the passages to and from a two-cycle cylinder are open, is about half that in the four-cycle. On this account it is better for extremely high speeds to lengthen the time of admission to the base by the use of some such device as a rotary sleeve valve.

Even running of the two-cycle at low speed is simply a question of port design. Just as in the four-cycle, flexibility and smooth running at low rotative speeds means sacrifice of power at very high speeds. There is nothing to be gained by avoiding base compression. Differential pistons, separate air pumps, and like schemes only complicate the engine, and the final result in horsepower per pound of engine shows no material gain. It further takes away one of the best points in favor of the two-cycle, its extreme simplicity.

No Loss of Power

Another false notion that has crept into the minds of the many regarding the two-cycle is loss of power with use, due to leaks by the bearings. Careful design, supported by good workmanship, practically eliminates this feature. It is an actual fact that, in spite of the great care taken in fitting and preliminary running in, I found my aeroplane engines to gain in power with use.

Mr. Gunn speaks in his letter of "The various devices put on, to make the two-cycle motor operate in a satisfactory manner." If these various devices were to be thrown into the junk heap and forgotten, the two-cycle would have a better chance of getting the recognition it deserves. It is these devices and the freak designs of this type that have done more to hold it back than any one thing. My experience is that the first thing the average designer does, when designing a two-cycle, is to devise a number of "improvements" to correct faults that do not exist outside of his imagination. If the engineers, who are now wasting their time with these absurd contraptions, will devote an equal amount of energy to the study of the base compression two-cycle, the type will make some progress.

There is nothing the matter with the base-compression type of two-cycle. What has been holding it back has been poor design coupled with a class of workmanship that would not be tolerated in a country garage. With one or two exceptions, the class of workmanship on the two-cycle cars that were formerly on the market was nothing less than atrocious. Many of the two-cycle marines were, and are to-day, little better in this respect, but the builders of the marine two-cycle have learned more from experience than the builders of two-cycle automobile engines did in the past.

Given equally careful study, with the elimination of false notions from our investigations, the two-cycle may be made fully equal to the four-cycle in flexibility, fuel economy and ease of starting. This is not a wild statement, based on prejudice in favor of this type, but is founded on the fact that I have seen and operated a two-cycle automobile engine which completely fulfilled these requirements. The engine was a base-compression type, and the results were due to a carefully conducted series of tests on the road, backed by careful design and good workmanship. It was particularly unfortunate that the promoter of this car was unable to get sufficient financial backing to place it upon the market.

In conclusion I wish to refer to the fear expressed in the letter of F. N. Nutt that "The present low-test gasoline will cause considerable trouble with the two-stroke motor." This is a very good example of the tendency to jump at conclusions on matters pertaining to the two-cycle. Low-test fuels are the two-cycle engine's long suit. It is the best kerosene engine of the two types. On California distillate, it will operate fully as well as on gasoline.

Tony Jannus in his flight over the Missouri and the Mississippi rivers from Omaha to New Orleans in the Fall of 1912 found the gasoline getting worse, the farther south he went. After leaving Memphis, he got a grade that he stated was almost kerosene. Yet his two-cycle engine worked equally on these grades, and the only difference apparent was greater difficulty in starting.

Two-Cycle as Ultimate Type

I venture to prophesy that after the two-cycle has been stripped of the utterly baseless notions in regard to it that now prevail, and the same amount of careful research has been applied to this type that has brought the four-cycle to its present state of perfection, it will be selected as the ultimate type of automobile motor.

The History of the Pneumatic Tire—13

Use of Rubber Tires of Bicycle Type on Sulkies and Hansom Cabs—Carriage Tires Developed in 1892—Pneumatic Wins Popularity on Bicycles

The History of the American Automobile Industry—40

By David Beecroft

PRACTICALLY all this early tire activity centered around the bicycle but the carriage began to attract attention as a market for rubber tires, also. The track sulky for speed purposes using bicycle wheels and tires and ball-bearings was found to be faster than the old form with high wooden wheel with plain bearings, and its adoption dates from about 1892, although a much smaller sulky, driven by a boy and drawn by a dog, had been exhibited in a great many cities in 1891. Sterling Elliott, the maker of hickory-wheeled bicycles, was largely responsible for this movement, and Bidwell tires were fitted in 1892, as were also Sercombe-Bolte tires, and others.

First Commercial Carriage Tires

Some British hansom cabs were fitted with two rims and springs or cushions of rubber rings between them in 1892, but this form did not survive, although somewhat lighter and less noisy than the steel springs of Whiting. The real commercial development of the carriage tire seems to have been begun in 1892 by the Springfield Rubber Tire Co., of Ohio, which first put out a round tire with a hole through it in which was a wire, a form on the market practically ever since. Later, this was followed by the D-shaped tire having two holes in the base for wires which was found to retain the rubber much better than a single wire. It was put on the market in 1894 by the Rubber Tire Wheel Co., of Springfield, Ohio, and a modification by the Victor Rubber Tire Co., of the same place, about 1896, in which the wires were covered with fabrics or encasements.

Improvements in Construction

Later, a further improvement in these solid tires was introduced by making ledges along the base in which the retaining wires could be placed by being forced over the edge of the rim. The result of this construction was a slightly wider rim in proportion to the width of the tire above the rim, but the great advantage was that the rubber was firmly held at its very edge by these wires and could not be rocked or rolled out of the rim. Further, the tire could be made endless and thus avoid a joint which frequently gave trouble and the wires could be welded or brazed together before being applied instead of this being done by holding open the joint for this purpose as is common with the two internal wires.

Solids for Motor Buggies

These forms, while in constant use on carriages to-day, did not find much acceptance on automobiles. Perhaps the experience of one pioneer is typical of others. The *Chicago Times-Herald* race winner, Duryea, was fitted with round, single wire cushion tires when first put on the road in March, 1895, or a little earlier. These were quite large as tires went in those days but the excess weight and service cut them out in a few weeks and they were replaced with 2-in. single tube pneumatics in May or June, 1895.

The solid tires had quite a boom for use on motor vehicles in connection with the motor buggy industry that began about 1900 and grew quite rapidly just before its slump in 1909. The attempt to secure cheapness in these buggies resulted in undersized tires being used and they wore out quickly. They also failed to protect the cheap, flimsy machinery too often used and were simply another example that, in the early days at least, or with poor constructions, the pneumatic tire was a necessity for a motor vehicle which was operated to the ordinary extent.

Pneumatic Comes into Its Own

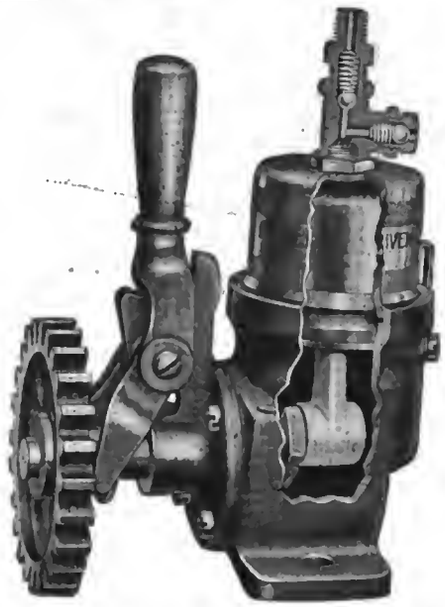
To continue a list of the various proposed designs of pneumatic tires, brought out in 1892 and 1893, would be a publication of names rather than any particular addition to information. Generally speaking, the solid or cushion tire had disappeared from the bicycle by 1892 or the latter part thereof and the pneumatic tire had taken its place. Three fairly well-accepted forms of the double tube pneumatic tire rapidly went to the front and their competitors of wide variety dropped by the wayside. How many of these there were is partly illustrated by the wide variety of rims shown in the advertisement of Warwick, a British manufacturer, in the Nov. 3d issue of *Referee*, 1893. Of these three forms, the cemented tire was cheapest and most common, its casing being split for a short distance on the base to permit inserting a tube having closed ends.

ACCESSORIES

Crane Power Tire Pump

IN the Crane single-cylinder power tire pump a special patented alloy packing ring is used instead of the piston rings usually employed in power tire pumps, the manufacturer stating that this ring is so arranged between the piston and the cylinder walls that leakage cannot occur and oil is prevented from getting into the compression chamber, and hence cannot reach the inner tube. It is claimed the efficiency of this construction is 97 per cent.

Pumps can be supplied for any make of car and the work of installing may be done by the car owner, no drilling of holes or machine work being necessary, as the brackets are designed for attachment to bolts or studs already on the engine. The question of drive connection is solved by the use of split gears designed to fit the car on which the pump is to be mounted. With hose and pressure gage, the pump sells for $8.—Bay State Pump Co., 275 Congress Street, Boston, Mass.



Crane power tire pump, showing patented alloy packing ring

Badger Gage for Fords

This device is combined with the filler cap and screws into the opening in the tank. The dial is marked for gallons and registers up to 10. Price, $1.25.—Badger Crafts Shop, Sheboygan, Wis.

J. B. D. Resilient Wheel

A housing built around the hub of the wheel contains a set of nine rubber disks arranged in a circle; the hub carries a plate with notches fitting the disks and a corresponding plate is carried by the wheel, the drive passing from the inner to the outer plate through the disks. The housing is of malleable iron, the wheel proper of wood and the disks of a special rubber which the makers state is good for from 15,000 to 20,000 miles and can be replaced for 20 cents each. The only attention required is the application of graphite three or four times a year. For Fords and other light cars. Price for four wheels without tires, $60.—J. B. D. Resilient Wheel Mfg. Co., Milwaukee, Wis.

MacDonald Cleaner and Primer

This engine-cleaning and priming device consists of two glass containers. These are interchangeable, and are connected, through a needle valve, by a copper tube to the manifold. The valve is governed by a button and the whole apparatus is fastened to the dash. For priming, a solution of 1 pt. of high-test gasoline and ½ oz. of commercial ether is placed in the container. The charge is released by the button and passes, by the syphon process, to the cylinders just after the engine is stopped. It remains in the cylinders until the engine is turned over, when it is fired instantaneously. For cleaning purposes the second container is used when filled with a solution of salt and water. As the contents of the jar are released, the extreme heat of the motor superheats the salt, which oxidizes the light carbon dust. The water is vaporized when it hits the firing chamber and becomes superheated steam, which drives the oxidations through to the exhaust.—F. A. MacDonald, Grand Rapids, Mich.

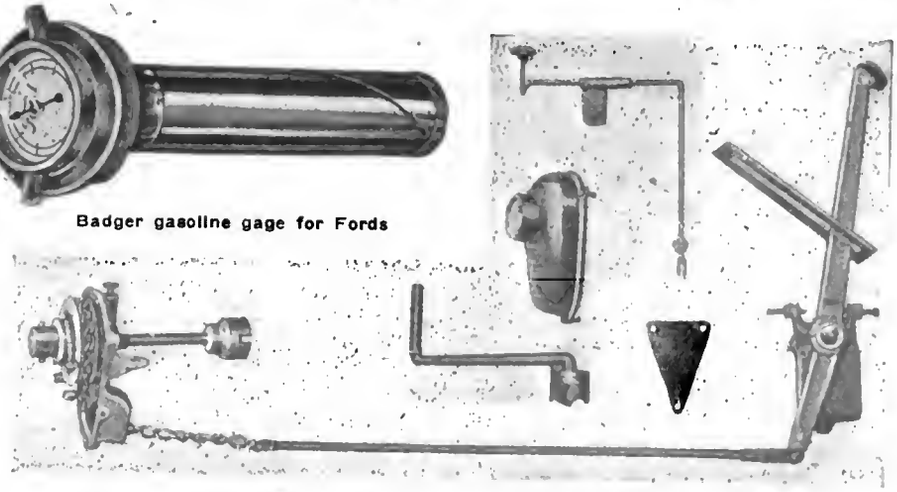
Badger gasoline gage for Fords

Shur-Go Starter

This is a pedal-operated starter designed for Fords, and consisting of a ratchet pulley attached to the crankshaft and which is rotated by a chain passing over another pulley and connecting to the lower arm of the pedal by a long rod. Price, $17.50, installed.—Peoria Specialty Co., Peoria, Ill.

Cutler-Hammer Rheostats

Two small rheostats to control the charging of starting-lighting storage batteries when a charge from an outside source is necessary, or charge lighting batteries when there is no generator on the car. The smaller model is for wall mounting; it has several resistance units inclosed in a sheet-iron case, and a slate panel carries several contact buttons, switch lever and binding posts. The smaller model, G, is made in two capacities—2½ and 5 amp. and 5 and 10 amp. respectively—based on 115-volt direct-current supply and the usual three-cell 6-volt battery in series. The larger model is particularly suited for service in garages and will charge any number of cells up to forty-four lead type and sixty Edison on 115-volt supply, or eighty-eight lead and 120 Edison on 230-volt supply. The larger model has a sheet-metal cas-



Shur-Go pedal-operated starter for Fords

Cutler-Hammer garage rheostat

ing for wall mounting, containing the resistance units and carrying a slate panel on which is a movable arm working over thirty contact points. When required, a double-pole knife switch for the main line, an ammeter and a voltmeter can be mounted on the panel. The ammeter is permanently connected in series with the rheostat and indicates the charging current at all times. The voltmeter has a 15-volt scale and is intended for use with flexible leads so that the voltages of separate cells can be obtained at any time.—Cutler-Hammer Mfg. Co., Milwaukee, Wis.

Searchlight Oxy-Acetylene Outfits

A complete oxy-acetylene outfit for welding and cutting is put up in a case, the set including the following items: 20-in. welding torch with seven tips and hose connections, 3½-in. acetylene regulator with 300-lb. and 50-lb. gages and connections, 3½-in. oxygen regulator with 3000-lb. and 150-lb. gages and connections, 10-ft. high-pressure black acetylene hose and clamps, 10-ft. high-pressure white oxygen hose and clamps, wrench, goggles and instructions. The weight of the outfit is 28½ lb. The oxygen regulator may be used in connection with a cylinder decarbonizer, which is furnished at extra cost. Price, $50.—Searchlight Co., Chicago, Ill.

Ames-Ton Truck for Fords

Worm drive is the particular feature of the Ames-Ton attachment for converting a Ford into a 1-ton truck. A heavy channel frame to support the truck body is bolted around and to the rear of the Ford frame. The weight of the truck is carried on half-elliptic springs; 3-in. expanding brakes are fitted. The wheelbase is 120 in., tires 32 by 3½, and rear wheels are of hickory, with 2-in. spokes. Tread is 56 in. and the loading space, back of the driver's seat, 8½ ft. It weighs 1100 lb., which added to the weight of the Ford chassis brings the unit up to 2000 lb. The gear ratio is 6.2 to 1. The price is complete with all fittings, and the change may be made in a few hours, it is said. Price, $395.—Ames Motor Car Co., Owensboro, Ky.

Cutler-Hammer small rheostat

Searchlight oxy-acetylene outfit

Amco swiveled spotlight

Amco Spotlight

This light is mounted on a swiveled bracket attached to the windshield. The front glass is 5 in. in diameter, and at the rear is a 4-in. plate-glass mirror. Light is supplied by a 6-volt 15-candlepower nitrogen bulb. The clamp will fit any standard windshield. The body of the lamp is made of heavy sheet copper and the finish is velvet-black, except the rear part and hanger, which are nickeled. Weight, 20 oz. Price, $7.50.—Art Metal Mfg. Co., Cleveland, Ohio.

Aerofram Air Valve

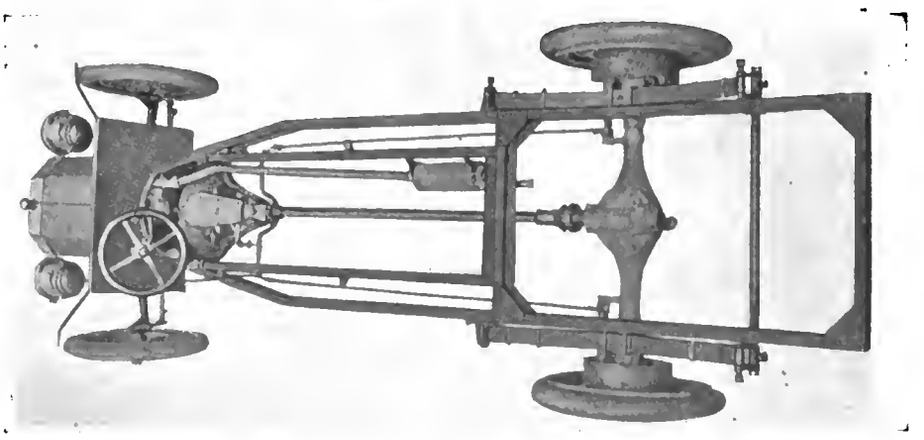
The Aerofram is a small spring-loaded automatic air valve which screws into the intake manifold and supplies extra air to improve the vaporization of the gasoline and to furnish the extra oxygen made necessary by the improved vaporization. There is nothing to adjust and the valve can be applied in a few minutes. It sells for $1.—The Aerofram Co., Inc., Boston, Mass.

Voss Auto Watch

The Voss Auto Watch attaches to the steering post by means of a clamp and spring bracket. It may be set at any angle desired. No screws or bolts are required and it can be put in place quickly or wound while the car is in motion. New watches may be obtained and secured in the case to replace an old or damaged watch. Price, $2.—Voss Auto Watch Co., Des Moines, Iowa.

Letter-Pack-It

An envelope for carrying a letter and a small bag for carrying merchandise sewed together, end to end, form a single package and avoid the necessity for sending the two separately. Spaces are provided on the envelope for first-class letter postage for the letter and parcel post stamps for the merchandise. Three sizes are made.—Letter-Pack-It System, Detroit, Mich.



Ames-ton worm-driven truck attachment for Ford cars

Caterpillar Tractors

THE article dealing with the good points of caterpillar type drives for tractors, of which the first part appears on page 184, is a result of experience extending over 11 months of use. Admittedly, the author, although entirely unconnected with the tractor industry, has had more to do with the caterpillar type than with wheeled tractors, and he may probably underestimate the advantages of the latter over the former.

Both the wheeled design and the caterpillar tractor are as much in their infancy as was the passenger car in 1900; we do not even know whether the truck type of engine is going to win out in competition with the heavy stationary gas engine sort. It is highly improbable that it will take 16 years to bring the tractor as near finality as the past 16 years have brought the passenger car. Rather, may we expect 6 years to settle the more vital questions, or even a shorter time, perhaps.

Meanwhile, it is experience that is needed; proper accounts of work done and money expended; full lists of troubles and repairs. Such will soon be available from the many farmers who are trying the modern method of cultivation. Just as we have more than one type of automobile so, no doubt, there will be more than one type of tractor always, and the caterpillar, even if it has great drawbacks, does seem able to perform some remarkable feats.

Exports Highest Yet

THE value of automobile exports from the U. S. for the year ended June 30, 1916, are only a trifle less than double the value for the previous year. Especially noteworthy is the fact that this is not due to the large exports of commercial vehicles, for of a total increase of $52,000,000, commercial cars only account for a little less than $18,000,000. Parts, excluding tires, have increased $15,000,000, leaving the balance of $19,000,000 to be credited to the passenger car increase.

In regarding this remarkable figure it must be remembered that Europe has been a closed market by reason of high tariff and, subsequently, prohibition of imports, since October, 1915. The detail figures for June, 1916, give the answer to the question of where these extra cars are going, for they show that the British colonial empire is buying a very large quantity and that the South American countries added together make a big total. It is obvious that America now has a firm hold on the markets which have been in the habit of buying largely from Europe, and it is a credit to the American industry that the loss of the important European market has been so much more than offset by the increase in other fields.

Ford

AT a time when raw materials are at the highest price ever known, and with the highest paid labor in any factory in the world, Ford drops his price 18.2 per cent. Why is it that such a thing can be done when almost every other motor car maker is *raising* prices?

The answer is that Ford has had a single aim, a single system, a steadfast purpose; unchanging for year after year. At the very start Ford's ambition was to do just one thing, and to do it better than anyone else in the world; his aim to-day is just the same as it was in the beginning. Ford has always stuck to the highroad of his choice, has never been led off down a side turning. His progress is something like that of a man who starts to drive across a strange city; he has made best time by choosing just one of the many avenues and sticking to it. He has never tried to cut across into another because of a rough patch ahead, on *the chance* that the unknown street would be smoother.

Ford stands as a great example, not only to the automobile industry, but to all industry, a great example of the enormous success obtainable from one thing done well. The temptation to depart from the original idea must many times have been enormous; that no such departure could possibly have been advantageous admits of no argument.

His work recalls those immortal lines of Owen Meredith:

"The man who seeks one thing in life—and but one—
May hope to achieve it ere life is done.
But he who seeks all things wherever he goes
Only reaps from the hope which around him he throws—a harvest of barren regrets."

Australian Industries Are Prosperous

Financial Conditions Throughout Continent 95 Per Cent Normal—Over 60,000 Cars in Use and Market Growing—Three Tire Plants—Body Building Progresses

NEW YORK CITY, July 29—Financial conditions in all of Australia are approximately 95 per cent normal, according to Peter McIntosh of McIntosh & Sons, Ltd., Sydney, who has been visiting in this country for several months. In spite of the war Australia is enjoying more than ordinary prosperity, largely due to the wartime prices being paid for so many of her natural products, such as grains, meats, wool, etc.

The financial situation in Australia is best demonstrated, according to Mr. McIntosh, by the quick subscribing for the different war loans. The first war loan of $25,000,000 was oversubscribed, there being $65,000,000 actually offered. The second war loan of $50,000,000 was subscribed to the extent of $110,000,000, and the new loan of $250,000,000 which is being talked of will be more than doubly subscribed, according to present indications. These facts indicate that there is plenty of money in Australia.

Nearly 70,000 Cars

Automobile business is suffering more or less because of the high ocean freight rates and the inability to get ships, as well as to the high price of gasoline. Australia has between 60,000 and 70,000 cars. Approximately 20,000 were sold during 1915. As in America, 70 per cent of the cars sold in Australia are going to the farmers. The term farmer must be interpreted somewhat differently than in this country. Many of the Australian farmers are large property owners and have huge herds of live stock. Others are engaged solely in mixed farming. Ford is the biggest seller, and is followed by Overland, Buick, Studebaker, Dodge, Chevrolet, Maxwell and others.

Due to the fact that gasoline is selling wholesale at Australian seaports at 60 cents per gallon—the imperial gallon is used—it is necessary to talk gasoline economy in making sales, and those dealers engaging in quantity business must be capable of showing 23 to 30 miles per imperial gallon. The imperial gallon is approximately one-sixth larger than the gallon used in this country. All of the gasoline used comes from the island of Borneo and is handled in 5-gal. cans, with two cans crated together. This method of handling is expensive and there is a movement on hand to introduce the bulk system, the same as used in the United States.

Lubricating oils are much more expensive than here. The price in such cities as Sydney, Melbourne, Adelaide, Brisbane, New Castle and Perth averages $1.50 per gallon, as compared with 50 cents here.

Three Tire Plants

Australia is not an automobile-manufacturing country, but has made much progress in the manufacture of pneumatic tires and also of car bodies. The three tire factories employ from 3000 to 4000 men and are producing upward of 2500 pneumatic tires per day, which is sufficient to practically care for all of the cars in the country. Tires sell for approximately twice as much as they do in North America. Because of the manufacture of tires in Australia the majority of the Australian dealers buy their cars from the United States without tires, this being to develop the tire business in Australia and assist the three tire factories there. The majority of Overland and Cadillac cars, however, are shipped with tires. Australia uses metric sizes, and the majority of tires are clincher type. Some straight-side types are being introduced into Australia; but there seems to be a preference for the clincher type, a condition naturally favored by the Australian manufacturers. One of the tire factories is the Dunlop, which is a branch of the English company; the other two are local organizations.

Body Building Important

Body building in Australia is an important industry and is a development of the old carriage trade. The Government has recognized this body-building industry and is protecting the local manufacturers by a heavy import duty. The present duty on a five-passenger body is $125. Because of the local body-building industry many Australian dealers prefer to buy stripped chassis in the United States and have bodies fitted in Melbourne or Sydney, where the body-building interests are centered. A good five-passenger body costs approximately $450 in these cities. There is not much economy in having the body built as compared with buying the chassis fitted with the standard factory body. In purchasing chassis without bodies from the American manufacturer approximately 50 per cent of the real cost of the body is generally remitted by the manufacturer.

Australian dealers and garagemen are generally well fitted to handle all matters with regard to car repairs, etc. When electric lighting and starting were introduced there was some difficulty at the start in obtaining efficient help, but the work of the Delco company in having its representatives visit all Australian cities for the purpose of educating dealers and garagemen in caring for such apparatus helped very materially. It is not now difficult to obtain good electrical experts, who generally are of French or Swiss parentage.

Battery Troubles

During the past season the battery question has been giving more trouble than perhaps any other, and it is not yet settled. Australia has a climate which is fairly severe on batteries, in that the summer is particularly hot; and with a temperature of 125 deg. Fahr. in the interior during the summer months of December, January and February, there has been more or less trouble with plates warping from the heat so that positives and negatives squeeze the separator so as to form a short circuit. In the coast cities, such as Sydney, the summer temperature rarely rises above 80 deg., so that there is no difficulty in such places.

Some of the battery manufacturers are improving their batteries by extending the separators a certain distance below the plates, thereby making it impossible for the bending of the plates to bring positives and negatives together and cause short-circuiting.

Lack of Standardization

The major complaint that many Australian dealers have with regard to batteries for starting and lighting is the lack of standardization, particularly in terminals, which makes it difficult to meet all the exigencies. With the present lack of standardization it requires about forty different models of batteries to care for all of the different American cars in Australia, so that any Sydney or Melbourne dealer or supply house aiming to be ready to meet any exigency in the battery field would have to be stocked to that extent.

It has been suggested that if greater standardization of terminals were accomplished four or six different models would suffice. This would make it much easier for the automobile supply man in Australian cities.

Mr. McIntosh when speaking on this subject said:

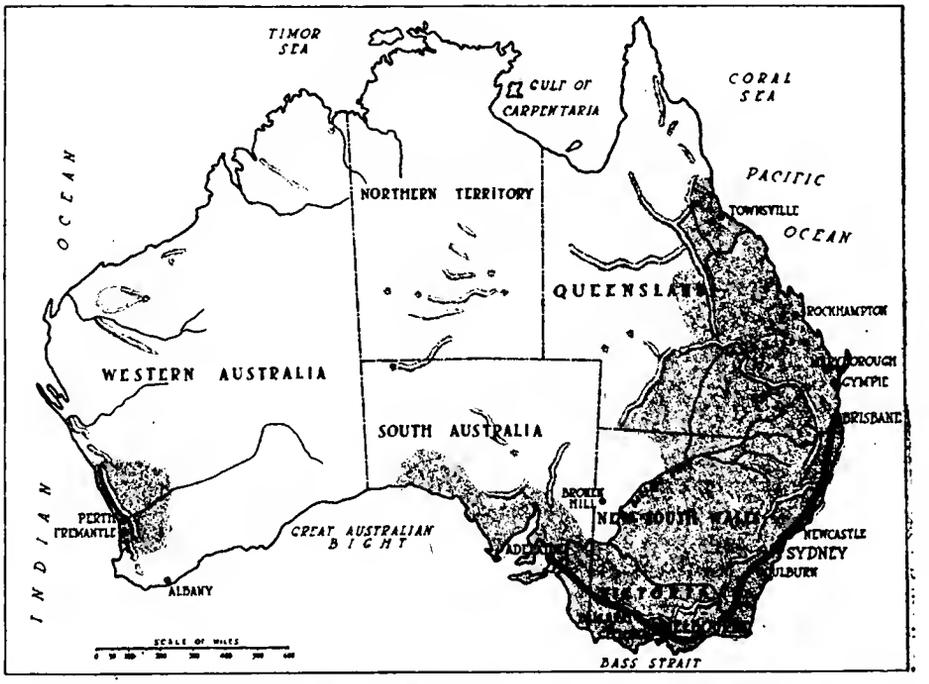
"There are three sizes of batteries that would serve at least sixty or seventy makes of American cars, and after close investigation there are not three different makes out of this number that could be connected up to any one battery model without making alterations in terminals or connections. If standardization were carried out a dealer or service department in a foreign country could replace the battery of almost any American car out of a stock of four sizes. As matters stand to-day, it requires a stock of forty different battery models, and then the dealer is not absolutely certain that he can do it."

A Growing Market

Australia as an automobile market is going to increase. At present it has been absorbing cars at a satisfactory rate in proportion to the population. With a population of 5,000,000, it has, say, 70,000 cars. On this ratio, with a population of 105,000,000, which is the same as that of the United States, it would have 1,470,000 cars. Australia's ratio of cars to population is thus scarcely one-half of that of the United States. Australia has a particularly homogeneous population. Colored races have largely been barred, and it is due to such prohibition that the population of the continent is not higher. With its present almost pure white population the buying capacity is higher than it ordinarily would be with heavily mixed races. There are islands in the Pacific Ocean with populations of 30,000,000 but which cannot be compared with Australia in purchasing capacity.

Australia has not yet taken up the road-building movement as it should. There are approximately 1800 miles of substantially improved highways. Between Sydney and Melbourne, a distance of 600 miles, there is a good road. These cities have populations of 800,000 and 700,000 respectively. From Melbourne to Adelaide, another stretch of 600 miles, there is a good road. The population of Adelaide is 200,000. From Sydney to Brisbane, 660 miles, there is another good macadam road. Brisbane's population is 150,000.

These three links of roads are all connected in the form of a huge crescent, as these four cities are located in the southeastern part of the continent, and, starting from the left-hand side of the crescent and going to the right-hand, the cities in order are Adelaide, Melbourne, Sydney and Brisbane. All are seaport places. All of this 1800 miles of highway



Map of Australia, showing the 1800 miles of substantially improved highways composed of the 600-mile stretch between Sydney and Melbourne, another 600-mile stretch from Melbourne to Adelaide, and a third of 600 miles from that city to Brisbane. Road development in other sections has been slow. Shaded portions indicate automobile districts.

was built some years ago and, owing to the present government system of roads, improvement has not been rapid since that date. The motorists are working for improved systems so that trunk highways will be extended into the interior. Considering the present road system in Australia and the population of the continent, the sale of cars has been particularly heavy.

Dealers' Expenses Heavy

The United States car manufacturer may find difficulty in realizing the cost to which the Australian dealer is put because of ocean freights, import duties, etc. Take a typical United States car that would retail in this country for $750. It costs approximately the same amount to get this car into the dealer's salesroom in Melbourne or Sydney. Some of the major items are freight from New York to Melbourne or Sydney, freight from the factory to New York, packing at the factory, duties of various sorts, etc. The following tabulation gives some conception of these expenses:

Packing at factory	$26.00
Freight, factory to New York	30.00
Freight, New York to Melbourne	320.00
Duty on body	125.00
Chassis duty, 10 per cent	50.00
Tires, 60 cents a pound	50.40
Duty, lamps and accessories	28.00
Duty, top and windshield	30.00
Exchange, commission, insurance, etc.	70.00

The question of exchange, commission, insurance, etc., is one that is generally little understood with American dealers, as they have not to bother with it. It costs approximately 2½ per cent for conversion from United States currency into Australian; that is, the Australian dealer pays approximately this much on his bill. In addition, exchange costs 2½ per cent between Melbourne or Sydney and New York. Marine insurance costs approximately 2 per cent. If the Australian dealer operates through a New York shipping house or exporter he pays 2½ per cent for his service. All told, there is 10 per cent added because of these four items. It is possible to eliminate the 2½ per cent commission to the exporter if the Australian dealer can do his business direct with the United States.

Freights have gone up very materially on the ocean because of the war. Before the war freights were $8 per cubic ton, and since the war they have risen to $40 and $45. During the past few days there has been a reduction of approximately $10 per cubic ton. A cubic ton is equivalent to 40 cu. ft., and a medium-price car selling around $800 occupies approximately a 9-ton space, or 360 cu. ft. Freight rates from Liverpool to Sydney before the war were $8 per cubic ton and are now $30. These figures apply, of course, to automobile shipments.

Armored Cars for U. S. Warships

WASHINGTON, D. C., July 29—Armored automobiles cradled on the decks of warships, in seagoing rafts, for the use of detachments of the United States marine corps in shore operations, may soon be added to the regular equipment of naval vessels.

Experiments at the Boston navy yard have demonstrated that these cars can be stowed aboard by the means of electric cranes on war vessels in a few minutes and take up small deck space.

Quotas and Their Use in Salesmanship

System Makes Use of Estimates Each Year Based on Past Performance, Business Conditions, Business Population, Size of the Company's Organization and Factory Capacity

IN his talk on Quotas at the recent World's Salesmanship Congress at Detroit, F. H. Dodge, sales manager of the Burroughs Adding Machine Co., Detroit, Mich., stated that his company is a firm believer in the use of quotas in salesmanship. In developing the quota system the company estimates at the beginning of each year the amount of business it should be able to secure, this estimate being based on past performance, business conditions, business population, size of the company's organization and factory capacity. In further explaining the application of the quota system, Mr. Dodge said:

For example, let us suppose our quota for this year to be $10,000,000 or 400,000 points; $25 worth of business represents a point; about twelve points represents an average sale.

Our first move would be to split these 400,000 points into 121 sections, because there are 121 Burroughs agencies in the United States and Canada. Quota sections vary in size according to the sizes of the agencies—as based upon territory values.

Agency Quotas by Months

Our next move would be to distribute the agency quotas by months. Agency quotas are not divided into twelve equal parts, for experience has proven, in our case, that with a corresponding effort more business can be secured in December than in January. Our June business has, also, always exceeded our July business. Other variations in monthly quotas are likewise necessary.

The proportion of our year's quota assigned to each month is as follows:

January	8%	July	7%
February	7%	August	7%
March	8%	September	8%
April	8%	October	8%
May	8%	November	9%
June	10%	December	12%

Our only stipulation in assigning salemen's quotas is that 720 points shall constitute a minimum year's quota for a salesman. We made the minimum quota 720 points, or $18,000 worth of sales, because that is the minimum account of business we expect a fair salesman to produce in a year.

A smaller business does not yield a profit sufficient to attract the class of salesmen we wish to employ.

When we find a sales manager has cut territories so small that, if properly worked, the salesman cannot secure a 720 point business in one year, we insist that the salesman's territory be increased in size.

I have now explained how we establish the company quota, how it is distributed by months and agencies and by sales managers to salesmen, but I have not touched upon another important condition in our quota scheme; that is, territory valuations.

How to determine with reasonable accuracy the various territory values has been one of our real problems.

We do not claim, even after twelve or thirteen years' experience of quota building, that we have the problem solved, but each year we are getting nearer to the ideal situation.

The deeper we go into the subject of quotas, the more certain we are that it is worth while and that there is much to learn about scientific quota building.

In the early days, we used population as the basis for determining territory values. Population is still used in our quota plan, but not alone.

To obtain a good guide to territory values, it was found necessary to supplement population figures with other statistics and data.

The sales value of population varies in different sections of the country; at least we have found it so. For example, 10,000 population in Texas, California, and in the Northwest was proved to be of greater sales value to us than the same population in the Central States or the East Coast States.

Reasons: Extensive credit systems in use in the South require more bookkeeping, consequently more adding machines for each unit of population.

In California and the Northwest, more young men educated to modern business methods are conducting the business of those sections.

These and other conditions naturally account for the variation in population values to which I have referred.

Accessibility of Prospects

To supplement the influence of these variations in population values, we later took into account past performances, accessibility of prospects, business conditions, and business or trade population.

The accessibility of prospects was found to be an important factor because this governed, to a certain extent, the amount of time salesmen could spend in the presence of each P. B., prospective buyer. Thickly settled territories should naturally carry larger quotas than sparsely populated territories.

Business population was our next important addition to the group of quota factors. It was in 1909, I believe, that we started to analyze territories to determine their business population. The Rapid Addressing Machine Co., of Chicago, made our first tabulation of business prospects.

Analysis of Previous Sales

Our first move toward this tabulation was to analyze carefully our previous sales to determine the most productive fields. We were then making a rather respectable showing in ninety-six lines of business. We gave this list of lines of business to the Rapid Addressing Machine Co., and this firm in turn made a tabulation of their lists by states, by lines of business and according to certain financial ratings which we specified. Their list was compiled from Dun's and Bradstreet's supplemented by other sources of information with which we were not entirely familiar.

In those days we had fewer agencies, and State lines, to a certain extent, became our agency boundary lines. Our lists were, therefore, compiled according to the business population of each State.

During the next two years, we did considerable cutting of territories and then, of course, found need for a business population tabulation by counties.

We purchased this information from the Boyd's City Dispatch, New York, at a cost of $1,000 plus an additional cost for copy work. I do not recall the cost of the copy work.

The second list was much better than the first, because with business population by counties to guide us, we were in better shape to ascertain the actual territory values.

In 1909 we were compelled to prorate values according to business population where two or more agencies were within one state.

Prior to 1909, the year business population by counties was introduced, it was not always easy to convince the sales manager that quotas were fair. Since that time, we have had very little trouble of that nature; for, generally speaking, the field men know that we know, prob-

ably better than they, the actual quota value of their respective territories. We have the real figures to prove the values. There is, consequently, not much excuse for fault finding.

In the early days of our quota experience, we were making only a few models of machines. We now make nearly 200. Therefore, a further refining of our quota plan was necessary to obtain good representation for the models of the long line. Various machines in the long line now carry separate quotas as do certain very productive special fields or lines of trade.

The more recent refinements in our quota scheme are necessarily more complex and would not be readily understood by one familiar with our business.

Quota enters into many phases of our business building plan. The per cent of quota secured indicates to a certain extent the relative ability of salesmen. Without these figures we would not be able to determine as well as we can now the men who are most entitled to promotion.

Friendly rivalry within an organization, if properly inspired, helps business. We use it extensively.

It would not be possible to use this rivalry as we do if we had no agency and individual quotas.

Our sales bulletin is issued each month and contains quotas, points secured, and the per cent of quota made. We make a practice of featuring in sales bulletins creditable records of individuals and agencies.

105,488 Cars in Bay State

Registrations for 6 Months Compare with 102,533 for Entire Year of 1915

BOSTON, MASS., July 29—Massachusetts registrations for the first 6 months of 1916 show a great jump over the same period of 1914 and over the entire 12 months last year. There was listed July 1 here 105,488 motor vehicles. For the same period in 1915 there were only 83,868 booked, a gain of 26 per cent, or 21,620 machines. During the entire 1915 period there were 102,633 cars registered so that the gain to date over all of last year is 2855 cars. And it is expected that there will be at least 125,000 machines registered in Massachusetts before the year ends due to the big demand the dealers are having now. The gain in trucks shows to greater advantage comparatively. Of the registrations above 14,800 were commercial vehicles. For the same 6 months of a year ago there were 9900 registered, a gain of 4900, or about 50 per cent. For the entire 12 months of 1915 there were 11,960 registered so that to date there are 2940 more registered than all of last year. And the trucks sales are increasing. As a result of the increases the State has been enriched also in fees. During the first 6 months of 1915 there was paid in to the Highway Commission $999,254.90. Up to July 1 this year the State has received $1,232,164.63, or $252,639.63 more than for the same period of 1915, and $29,744.44 more than all the fees gathered in the 12 months of last year. Herewith are the figures.

Of the cars registered it is surprising that nearly 65,000 of the total is covered by just sixteen different makes. There are that many that have more than 1000 cars listed, the Ford standing far ahead, with 22,640. That is about 20 per cent of the entire registration. According to the figures as compiled by the Auto List Co. up to June 24 the cars are listed as in the table below.

Allen Holds Dealer Convention

FOSTORIA, OHIO, July 29—The dealers of the Allen Motor Co. held their annual convention at the factory last week. New cars were inspected and business and sales sessions were held.

Massachusetts Registrations for 6 Months in 1915 and 1916

	To July 1, 1915	Entire Year 1915	To July 1, 1916	Gain Over First 6 Months 1915	Gain Over Entire Year of 1915
Automobiles....	83,868	102,633	105,488	21,620	2,855
Trucks	9,900	14,733	14,800	4,900	2,940
Fees	$999,524.99	$1,205,420.19	$1,232,164.63	$252,639.73	$29,744.44

To Define Truck Requirements

Automobile, Military and Naval Men Study Mobilization Problems

WASHINGTON, D. C., July 31—Another meeting was held this week at the War College here to discuss plans for mobilization of troops and supplies in time of war, particularly so far as civilian organizations are concerned. Major Palmer E. Pierce of the General Staff Corps presided at the meeting, Lieut. Col. Chauncey B. Baker being present to represent the Quartermaster General's office. Representatives of the Naval Consulting Board, the National Automobile Chamber of Commerce, the Society of Automobile Engineers and the American Automobile Assn. committees were in attendance.

Information is being collected as to just how many government departments need a large motor truck equipment, in order that suitable specifications can be developed for each type of truck required. The Truck Standards Division as well as other Divisions of the Standards Committee of the Society of Automobile Engineers will, as in the past, take a leading part in this work. Serious attempts will be made to develop specifications of proper length, that is, neither too long nor too short, covering adequately the requirements of the government, which it is felt will eventually harmonize to a greater extent than has been expected heretofore with the needs of private users of commercial motor vehicles. Some well qualified experts feel that within 2 or 3 years the commercial product will approximate what according to the best opinion will be suitable for operation in all except special cases of government service. This is undoubtedly the best line of procedure, as it is not likely that a subsidy plan will be established in this country in connection with truck manufacture. Both the truck manufacturers and the government want to improve the current truck specifications.

Trucks Severely Tested

It is agreed that the tests to which trucks have been subjected on or near the Mexican border are the most severe that have been had in any part of the world. The conditions of service have been abnormal in that the lines of communication have been maintained without the use of railroads. The performance of some of the trucks has been wonderfully good, but there is room for further beneficial specification in various respects. The necessary engineering study is now being made, many of the S. A. E. members going to the Mexican border to view at first hand the unusual conditions of weather, sandy grit and alkali encountered.

The development of suitable tractor types of motor vehicle will also be given attention.

Regulations are being prepared for use in the organization of officers and enlisted men of the Reserve Corps recently authorized by Act of Congress. There will be a mobilization of the reserve organizations of a fortnight's duration each year. Reserve Corps officers will be appointed in sufficient number to make possible the assembly of troops at local points and transporting them to strategical points.

For Transportation

Past-president Wilson of the American Automobile Assn. announces that over 90 per cent of the millions of American pleasure car owners would very willingly and quickly tender the use of their vehicles under any suitable plan of mobilization. This will make possible immediate transportation preparedness which would be wanted in case of emergency. It is stated reliably that in many districts large bodies of troops can be mobilized by motor cars before the railroads operating in the respective districts can get sufficient cars ready to transport them. Demonstrations which have been made readily show that troops can be moved by automobile faster than by train.

Suitable types of armored cars for use by the ordnance department as well as types meeting the needs of the engineers, the signal and the artillery corps will be developed.

Emphasis was again placed upon the vital importance of good roads. It was pointed out that $225,000,000 was spent on good roads in this country last year and that in some of our territory we now have the best road systems in the world. Those in attendance at the meeting were:

Major Palmer E. Pierce, General Staff Corps.
Lieut. Col. Chauncey B. Baker, Quartermaster Corps.
Major L. P. Williamson, Medical Corps
Howard E. Coffin, Chairman Industrial Preparedness Committee, Naval Consulting Board.
Bion J. Arnold, Chairman Transportation Committee, Naval Consulting Board.
Alfred Reeves, Chairman Military Transport Committee, National Automobile Chamber of Commerce.
George W. Dunham, Member Military Transport Committee, Society of Automobile Engineers.
A. L. Riker, Member Transportation Committee, Naval Consulting Board.
H. D. Church, Chairman Truck Standards Division of Standards Committee of the S. A. E.
Wm. P. Kennedy, Member Military Transport Committee, S. A. E.
John A. Wilson, Chairman Military Preparedness Committee, American Automobile Association.
Amos G. Batchelder, Member Military Preparedness Committee, A. A. A.
J. S. Marvin, Manager Traffic Department, N. A. C. C.
W. H. Allen, Member Tire and Rim Division of S. A. E. Standards Committee.
Coker F. Clarkson, Chairman Military Transport Committee, S. A. E.

Gasoline Prices Down 1 Cent

New Jersey, the Carolinas and Part of Ohio Affected—Crude Lower

NEW YORK CITY, Aug. 2—The price of gasoline has been reduced 1 cent a gallon in New Jersey, North and South Carolina, Virginia and at most of the filling stations in Cleveland, and the Standard Oil Co. has dropped the price 1 cent in the Cincinnati section. Gasoline is now selling for 22 cents in New Jersey; 23 cents in Cleveland; 24½ to 26½ cents in the Carolinas; 22½ to 24½ in Virginia.

3-Cent Reduction

A close investigation of petroleum market conditions discloses the fact that within the last year there has been an enormously increased production of crude oil not only in Oklahoma and other Western fields, but in such oil districts as Pennsylvania and Ohio, and that as a result of this the price of gasoline may drop from 1 to 3 cents under the present market price.

In Pennsylvania alone 60,000 old oil wells have been uncovered and reworked with satisfactory results. Wells producing 6 to 8 barrels of crude per day were not worth working when crude was selling at 40 cents per barrel, but when it rose to $2.65 per barrel, as it did in Pennsylvania, such wells proved very profitable. In Ohio 25,000 old wells were reworked. In Oklahoma wells were sunk deeper and in other oil producing States similar conditions prevailed.

As a result, the market is not prepared to take care of this increased supply and storage facilities to care for 100,000,000 barrels of crude will soon be ready. This supply is practically equivalent to a 6 months' consumption of gasoline.

The greater use of the cracking process in gasoline refining as introduced by Doctor Burton of the Standard Oil Co. of Indiana, 5 years ago has made it possible to get practically double the quantity of gasoline from the crude.

The manufacture of gasoline from natural gas has greatly aided in relieving the situation, as the high price of gasoline made it possible to produce fuel from the gas by either the compressor or vacuum processes.

Further relief in the crude market is in sight due to the building of 50 tank steamers to be used in transporting crude from Mexico and the Gulf fields to the refineries.

Reductions in crude oil prices have been announced in the Mid-Continent, Ohio, Texas and Louisiana fields, falling from $1.55 to $1.25.

Studebaker To Add 40,000 Ft.

Extra Floor To Be Added To New Building—Plans Other Additions

DETROIT, MICH., July 27—The Studebaker Corp. has awarded contracts for construction work that will add 40,000 sq. ft. to the floorspace of the Studebaker factories. An extra floor, 50 by 300 ft., is to be added to one of the three-story buildings at present used as a warehouse for materials, so that the Studebaker plants may be better prepared to stock up on materials in advance of immediate needs.

A new one-story building to be used in connection with final assembly work is to be erected on the site purchased by the Studebaker company in May, adjoining plant No. 3 on the west side of Detroit. With the annexing of this property the total floorspace occupied by the Studebaker factories has been increased to 150 acres.

Authority to add ½ mile more of railroad siding has also been given, which will be in the nature of double railroad platforms, each one-fourth of a mile long.

The value of the construction work that has been authorized will run close to $100,000.

New Armleder Truck Prices

CINCINNATI, OHIO, July 29—Armleder trucks are now sold at a new scale of prices, as follows:

Model	Tons Capacity	Drive	Price
HC	2	Chain	$2,200
EC	2½	Chain	2,350
HW	2	Worm	2,400
KW	3½	Worm	3,250

A new series of the 2-ton worm-driven model will be announced very shortly. This new series is designated HW-2, and will be similar to the old series except for minor refinements of detail.

New Moreland Delivery Car

LOS ANGELES, CAL., July 25—The Moreland Motor Truck Co. has announced a new model, a light delivery truck, the chassis to sell at $990. This new model is a 1500 lb. capacity rapid service utility truck equipped with Wisconsin motor, Timken axles and roller bearings, three-speed transmission, and with solid or pneumatic tires optional.

Auto Body Co. Addition

LANSING, MICH., July 28—A further enlargement of the plant of the Auto Body Co. will occupy a large tract of land purchased adjacent to the factory, where a three-story factory extension will be built. It will front 75 ft. on Turner Street and run back 200 ft. west of Turner. The company has also made an arrangement with the New York Central railroad for the installation of a direct freight siding with that railroad from its plant.

Corman Is Denneem Sales Manager

CLEVELAND, OHIO, July 29—E. W. Corman has been appointed sales and advertising manager of the Denneem Motor Co., this city, maker of the Denmo truck. Mr. Corman left a similar position with the Elgin Motor Car Corp., Chicago, Ill., and was formerly with the Saxon Motor Car Co., Detroit, Mich.

Prine a Pathfinder Representative

INDIANAPOLIS, IND., July 29—H. W. Prine has been appointed district sales representative for eastern Pennsylvania for the Pathfinder Co., this city. Mr. Prine will specialize on carrying out the company's educational work among its dealers. He will make his headquarters in Philadelphia.

Devlin Joins Elgin Corp.

CHICAGO, ILL., July 29—F. X. Devlin has resigned as purchasing agent of the Federal Motor Truck Co., Detroit, Mich., to become identified with the Elgin Motor Car Corp., this city. Mr. Devlin has been connected with the Federal company since its formation 6 years ago.

Hastings Is Empire Consulting Engineer

INDIANAPOLIS, IND., July 27—Don T. Hastings has recently moved to this city from Detroit to act in the capacity of consulting engineer to the Empire Automobile Co. Mr. Hastings was previously assistant chief engineer to the Hupp Motor Car Co.

Smith to Manage Buda Motor Sales

HARVEY, ILL., July 29—L. R. Smith, Indianapolis representative of Eisemann magnetos for several years, has resigned to become general sales manager for the motor department of the Buda Co., this city.

Budd Starts Plant Addition

PHILADELPHIA, PA., July 29—The Edward G. Budd Mfg. Co., this city, is having a factory addition built at Twenty-fifth Street and Hunting Park Avenue for the making of automobile bodies.

Kentucky Revivo Battery Petitions

LOUISVILLE, KY., July 29—Pursuant to a resolution adopted by the directors of the Kentucky Revivo Battery Co. Monday a voluntary petition in bankruptcy was filed for the concern July 25.

U. S. Tests Armored Truck

New Type Mounted on King Chassis Tried Out for Power and Speed

WASHINGTON, D. C., Aug. 1—An official test was conducted here to-day with the King chassis fitted with a new type of armored body. The tests were supervised by two members of the Marine corps and some army officers. The car was first given a hill-climbing test on a short steep hill on Thirty-fifth Street; it was then given another similar test on the road leading to Fort Myer; at Fort Myer it was driven through a prepared ravine through which water was flowing; lastly it was given a speed test at 30 m.p.h. at Fort Myer. The test continued from 2 o'clock until 5.

On Wednesday the car will be driven to Annapolis to be tested through 6 miles of sand and on Thursday it will be driven to Camp Biddle, Philadelphia, where it will be loaded on a transport and taken to sea. It will be out several days, during which landings will be made with the car intact and in five units.

Scripps-Booth Corp. Organized Under N. Y. Laws

NEW YORK CITY, July 29—Announcement is made by C. H. Booth, president of the Scripps-Booth Co., of the organization under the laws of the State of New York of the Scripps-Booth Corp., with a capitalization of 70,000 shares, no par value, of which 25,000 shares are to be offered for public subscription at $50 per share.

The Scripps-Booth Corp. is a consolidation of the Scripps-Booth Co., Detroit, and the Sterling Motor Co., also of Detroit.

The corporation will have no bonds or preferred stock and no floating debt.

Plant extensions are planned which will permit an output of 12,000 cars for 1917. The Sterling company has made the engines for Scripps-Booth cars since they were first built and now becomes a unit of the organization. The Scripps-Booth capital was increased from $100,000 to $350,000 early in the year following the entrance into the concern of Clarence H. Booth, who will head the new corporation.

Truck Man Home from War

NEW YORK CITY, Aug. 2—Granville A. Pollock, who has represented the Pierce-Arrow Motor Car Co. at the war front in Flanders, France, during the past 18 months, arrived home last week. Mr. Pollock had charge of anti-aircraft trucks.

Stutz Announces New Roadster

Bulldog Continued—Wire Wheels, Improved Carbureter and Roomier Bodies

INDIANAPOLIS, IND., July 31 — The Stutz Motor Car Co., this city, announces that its new models will have wire wheels as standard equipment, improved carbureters to take care of the present low-grade fuel, longer rear springs and roomier bodies. There will be an entirely new roadster model. A standard wheelbase of 130 in. has been adopted for all models, which will consist of the Bulldog Special with four and six-passenger bodies, and the new roadster. The price of $2,550 for the Bull Dog is the same, while the new roadster price is $2,275, an increase justified by a longer wheelbase and many refinements. The new roadster has a modified turtle deck with a depression in it for carrying the spare wheels, instead of the exposed tank and trunk as formerly.

—

Buffalo Pressed Steel Co. Expands

BUFFALO, N. Y., July 29—The Buffalo Pressed Steel Co., this city, has leased the John R. Keim mill property on Kensington Avenue, owned and operated but recently vacated by the Ford Motor Co. This property is particularly suited to the company's work and permits of substantial expansion.

—

Union Truck Elects Officers

BAY CITY, MICH., July 26—At a meet- of stockholders and others interested in the new Union Truck Co., directors and officers were elected. James R. Tanner, is president of the company; H. E. Woodworth, vice-president and general manager; E. C. Tibbetts, secretary and George Beaulier, treasurer; these officers and H. E. Buck, W. H. Boutell and C. E. Chatfield, form the directorate. The plant formerly occupied by the Marine Iron Works, Water and Second Street, has been secured and the Union truck is to be made there on a large scale. It is said that the new concern has ample capital.

—

Bowser Promotes Four

FORT WAYNE, IND., July 29—Four important promotions in the sales department of the S. F. Bowser Oil & Tank Co., this city, become effective Aug. 1. L. P. Murray, sales manager, is made mid-West manager; J. G. Rodman, executive assistant, promoted to central manager; E. J. Little, New York office manager, is named eastern manager, and E. H. Briggs, factory sales manager, becomes executive assistant.

Mr. Murray who has had charge of the store and garage sales department at Fort Wayne, will now have jurisdiction over the Chicago, Denver, St. Louis and Dallas offices. Mr. Rodman will supervise the offices in Ohio, Indiana, Michigan, Louisville, Memphis and Atlanta. Mr. Little will have charge of the offices in New York, Albany, Harrisburg and Washington. Mr. Briggs will now have charge of the sales promotion work. Clarence W. Kroener, machinist for the Bowser company, has been promoted to the position of superintendent of construction at Boston, Mass.

—

Four Wheel Tractor Co. Elects

CLINTONVILLE, WIS., July 31—The Four Wheel Tractor Co., a new Wisconsin corporation organized at Antigo, Wis., recently, and later purchased by Clintonville interests, has perfected its organization by the election of the following officers and directors: President, Charles Topp; vice-president, W. H. Finney; secretary, A. B. Mayhew; treasurer, L. C. Larson; directors, F. M. Hyde, Henry Zarling and Alex. Stewart. A plant is now being provided and production will start within 30 days.

—

Taber with Asbestos Protected Metal Co.

PITTSBURGH, PA., July 29—Melbert W. Taber, formerly manager of maintenance and construction of the Packard Motor Car Co., has been appointed manager of the Detroit office of the Asbestos Protected Metal Co., located in the Penobscot Building.

—

Tay-Miller Increases Capital

PHILADELPHIA, PA., July 29—The Tay-Miller Mfg. Co., this city, has increased its capital stock to $100,000 of a par value of $10 per share. The additional capital is to provide facilities to take care of the increased business in the company's patented Hand-I-Wash combination of water, soap and towel in a compact case.

Cassidy Gets Kimball Jack Sales

Takes Long-Term Contract for World—To Expand Production at Once

NEW YORK CITY, Aug. 1—The Edward A. Cassidy Co., this city, has completed arrangements with the F. W. Mann Co., Milford, Mass., to market the Kimball ball-bearing automobile jack throughout the world on a long-term exclusive sales contract.

Plans now under way for a rapid extension of manufacturing facilities will increase production to an annual output of 150,000 Kimball jacks, and it is understood that still further extensions will be made as conditions warrant. The Kimball jack will be standard equipment on the Franklin car, the H. H. Franklin Mfg. Co. having contracted for 10,000.

New Directors for K. C. Tire

KANSAS CITY, MO., July 28—At the annual meeting of the shareholders of the Kansas City Tire & Rubber Co., the following directors were elected for the ensuing year: P. E. Werner, F. A. Werner, W. W. Wuchter, L. J. Smith, Harry Goodman, W. R. Swissler and William Gould. A meeting of the board of directors will be held in Kansas City, and the business of organization and election of officers will be taken up thereat.

both payable Sept. 1 to stock of record Aug. 15. The payment of the same was the initial dividend of 3 months ago. It is reported that net earnings for the first 6 months of 1916 amounted to approximately $300,000 or twice the amount required for dividends. The company's new factory for miscellaneous rubber business is nearly completed and operations will begin early in August.

Dividends Declared

B. F. Goodrich Co., quarterly of $1.75 per share on preferred, payable Oct. 2 to holders of record Sept. 21. Also quarterly of $1 a share on common, payable Nov. 15 to holders of record Nov. 3.

Lee Rubber & Tire Corp., quarterly of 50 cents a share and an extra of 25 cents per share, payable Sept. 1, 1916, to holders of record at the close of business Aug. 15, 1916.

Daniels Capital Now $250,000

READING, PA., July 29—The Daniels Motor Car Co., this city, manufacturers of the Daniels eight, has increased its capital stock from $100,000 to $250,000.

Salisbury Wheel Doubles Capital

JAMESTOWN, N. Y., July 29—The Salisbury Wheel & Mfg. Co., this city, has increased its capital from $500,000 to $1,000,000.

Muskegon Foundry Grows

MUSKEGON, MICH., July 26—A three-story addition, 150 by 50 ft., will be erected by the Enterprise Foundry Co.

Stock Prices Are Dull But Firm

General Motors and Packard Show Gains, But List Is Inactive

NEW YORK CITY, Aug. 1—The automobile securities, both on the exchange and the curb, reflected the general tone of the entire list practically throughout the past week, although there were some brief fluctuations, the tendency as a rule being toward lower prices, although in almost every case recoveries took place, leaving the stocks in almost the same position as at the end of last week. The only issues to show material gains were General Motors, which picked up 20 points on the common and 5% on the preferred, and Packard common which gained 7 points. Other slight gains were 1½ points for J. I. Case, 1 point for International Motor common, and 1 point for Studebaker common.

Chevrolet headed the list of losers, having dropped 8 points, while Chandler declined 3½ and Willys-Overland common lost 2⅜. Ajax Rubber, Goodyear common and Springfield Body common each lost 2. There were several other minor losses, but a good share of the issues registered no change at the end of the week.

The Stromberg Carbureter issue was over-subscribed, and while the general attitude toward automobile and allied securities was one of watchful waiting, as in the case of practically all the other stocks, there seemed to be no difficulty in disposing of these issues, although the volume of trading was small.

The characteristics of the New York market were naturally reflected in the quotations on the Detroit exchange, although no losses were shown by active stocks in Detroit, General Motors common gaining 20 and Maxwell common 4½, with Maxwell first preferred up 1½ points and the second preferred 1 point higher than last week's. Among the inactive stocks Kelsey Wheel registered a loss of 100 points.

Lower Crude Features Markets

NEW YORK CITY, Aug. 1—The automobile materials market, like the securities quotations, showed very little change this week, the most important changes being a tendency to lower gasoline prices due to the drop of 10 cents a barrel in crude and advices from London to the effect that crude rubber prices were lower, manufacturers being indifferent to offerings and the same being true of sellers. This may reflect a decreased scarcity of rubber resulting in somewhat lower prices. Cottonseed oil was weak, closing 32 cents a barrel lower than last week, while rapeseed oil was 2 cents lower. Sulphuric acid lost 50 cents and lead was 15 cents cheaper per hundred pounds. The only increase in price noted was that of 1½ cents per pound and Ceylon first latex. All the other prices remain steady.

Indianapolis Race Sept. 9

Date Advanced from Sept. 4 Because of Conflict with Cincinnati Race Date

INDIANAPOLIS, IND., July 28—The local speedway officials have advanced the next racing date from Sept. 4 to Sept. 9 on account of the opening of the Cincinnati Speedway on that date. The Harvest Auto Racing Classic, as the event will be called, will be run in three races for cars known as non-stock and having piston displacement of 300 cu. in. or less. The races will be at 20, 50 and 100 miles.

The prize money will total $12,000. In the 20-mile event first prize is $400; second, $300; third, $200; fourth, $100. Two thousand dollars will be the amount the drivers will struggle for in the 50-mile event and will be divided as follows: $700 for first, $500 for second, $400 for third, $300 for fourth, and $100 for fifth. The 100-mile race, which may be run off as a championship event, permission having been asked the A. A. A. Contest Board, will be divided as follows: first, $3,500; second, $2,000; third, $1,200; fourth, $1,000; fifth, $600; sixth $400 and seventh $300.

19 Entries for Tacoma

TACOMA, WASH., July 31—While there is still more than a week in which to make entries in the Montamarathon and Golden Potlatch trophy 300-mile race to be held on the Tacoma Speedway, Aug. 5, indications point to a field of more than 20 starters.

The following entrants had signed July 26:

DePalma	Mercedes
Henderson	Maxwell
Chandler	Crawford
Rawlings	West Duluth Special
Moore	Peusun
Barsby	Hudson Special
Milton	Duesenberg
Frauchi	Delage

DeAlene	Duesenberg
Rickenbacher	Maxwell
DeVigne	Delage
Lewis	Crawford
Sorenson	Morse
Taft	Omar
Johnson	Crawford
Un-named	Gandy Special
O'Donnell	Hoskins Special
Price	Gandy Special

Marmon Breaks Record

(*Continued from page* 168)

The object of Mr. Stevens' trip was to demonstrate the value of good roads in quick military mobilization. Mr. Stevens is chairman of the Motor Reserve Division of the American Defense Society. The car was a Marmon stock model 34 roadster and is the privately-owned vehicle of Mr. Stevens, although the co-operation of the Nordyke & Marmon organization was afforded the car and drivers across the country.

The speed at which the car traveled may be judged from the fact that although it left New York at 1.30 a. m., it had arrived in Buffalo at 2.50 p. m. on the same day, having covered the 450.4 miles at more than 33 m.p.h. average. The car was in South Bend at 4.10 a. m. the second day and arrived at Merrillville, its nearest point to Chicago, at 7 a. m. the second day, having covered the 993 miles by the northern route in 30 hr. and 30 min. The car arrived at Omaha at 1.10 a. m. on the third day., Cheyenne at 4.50 p. m. on the third day, Salt Lake City 7.40 p. m. on the fourth day, Reno 5.30 a. m. on the fifth day.

Five Drivers

Five drivers divided the time, the greater part of the distance being driven by Mr. Stevens. The other drivers were Walter Bieling, Robert Creighton, Wm. Binz and Fred Barbour. The car was driven from New York to Syracuse by Mr. Barbour, from Syracuse to Cleveland by Mr. Stevens, Cleveland to Chicago by Mr. Binz, Chicago to Omaha by Mr. Stevens, Omaha to Cheyenne by Mr. Barbour, Cheyenne to Evanston by Mr. Stevens, Evanston to Ely by Mr. Bieling, Ely to Reno by Mr. Creighton and Reno to San Francisco by Mr. Stevens. A message was carried from Major-General Wood, commanding the Department of the East, to Major-General Murray, commanding the Department of the West.

Before the trip was started a schedule was laid out like that of a railroad timetable. This was closely adhered to until some difficulties of a mechanical nature and road irregularities were encountered toward the end of the trip. The car left Rawlins, Wyo., 35 min. behind schedule on account of muddy roads. The roads between Evanston and Salt Lake City were in bad condition and a wire from Salt Lake City reported that a torque rod socket had been broken in Parley's Canon, 16 miles from Salt Lake City. Repairs were soon made, however, and Bieling left with the car at 7.40 p. m. from Salt Lake City on July 27. Rain and washouts delayed the car just before entering Ely, and due to poor roads a broken wheel resulted along the same stretch. Due to the misguiding of a pilot 3 hr. were lost on the desert.

The trustees of the American Defense Society were keenly interested in the experiment and as chairman of the Motor Reserve Division Committee Mr. Stevens made the test directly under the auspices of this society. The drivers were under instruction not to exceed 50 m.p.h. at any time and the fact that the high average was maintained under these instructions gives a remarkable demonstration of regularity.

Pathfinder High Gear Run Ends

Twelve Crosses Continent Sealed in High—Makes 60 M.P.H. on Track

NEW YORK CITY, Aug. 1—The Pathfinder twin six which left San Diego, Cal., on July 3 to cross the continent on high gear arrived here to-day. The car was met by a delegation of Pathfinder owners and officials of the American Automobile Assn., being conducted to the Sheepshead Bay Speedway, where it was run over a measured course at 60 m.p.h. as a final demonstration.

The car was officially sealed in high gear by the A.A.A. through its representative, Al. G. Waddell of Los Angeles. The seals have been inspected frequently throughout the route by A.A.A. officials and officers of the Lincoln Highway, over which the car was operated throughout the entire distance. The mileage covered was 4921 at the completion of the mile test on the Speedway. After this it was taken to the New York agency and re-measured by officials to check up as a stock car.

Speed No Object

No attempt was made to acquire a high speed average, as the average distance traveled daily was 200 miles and no night driving, to any extent, was done. Four days were spent at various points along the trip in idleness, so that altogether the trip occupied 28 days. The car is geared 5 to 1 on high, this being the standard ratio that is sent out with cars to hilly territories.

Walter Weidely, son of George Weidely, designer of the engine employed in the car, drove practically the entire distance. He was checked in and out of every town of consequence along the way by hotel keepers, chambers of commerce, etc. The worst point along the route was Lucky Boy Mountain, Nev., where it required strenuous efforts to pull the car over on high gear. Rain was encountered at Rock Springs and Laramie.

10.2 M. P. G. Fuel

A gasoline consumption of 10.2 miles to the gallon was averaged over the route. The car carried a driver, mechanic and a number of spare parts, including a clutch and extra live axles which were never used. Two of the tires, both on the left side, had California air in them when the car arrived at New York. The right tires were changed along the route. The highest price paid for gasoline along the route was at Fish Springs, Utah, where it was 65 cents.

(*Continued from page* 169)

aging sign, for it makes plain that such contracts are not being signed merely on momentary enthusiasm or because of a type of hysteria peculiar to gatherings of the kind. Generally, careful investigation precedes the making of contracts.

That the demonstration will stimulate sales there seems no doubt. Of late, owing to a long-continued drought and to partial failure of wheat and corn crops, implement dealers and automobile men handling tractors have assumed a condition of lethargy which has not augured well for sales. In fact, sales have fallen off quite noticeably since the first of the year and tractor manufacturers look to this demonstration to bolster up the courage of dealers and to inject new life into the trade.

Stimulating Sales

The absence of rain throughout Kansas is having somewhat of a double-barreled effect. In the first place it has retarded the corn crop to such an extent that dealers state that if no rain falls within a short time fully two-thirds of their accounts will have to go over until next Spring. And in the second place it has left the ground almost stony hard where uncultivated, and given tractor manufacturers the hardest kind of plowing to do. A supplementary effect, and an altogether important one, is that no one of the tractors has failed to make good in the demonstration. Thus, farmers and dealers who would be impressed by tractor plowing under ordinary conditions are doubly impressed by the good work being done under the present adverse conditions.

It is true that during the first day of plowing many more or less tortuous furrows were plowed and that in some cases it was necessary to have as many as three men on a gang of three plow bottoms in order to get the plows in and to keep them in. But notwithstanding, this is not held against the tractors but is rather taken as an indication of their ability; for it is realized that horseflesh *could not* plow under similar conditions —that is, without at least four horses to a bottom instead of the usual two.

Make Dynamometer Tests

This year, tractor manufacturers and those who view the demonstrations have a definite means of knowing exactly how much work a tractor must do to pull its plows. Each morning, before the plowing is started dynamometer tests are made to ascertain the average draft per plow bottom in various parts of the field. These figures, obtained with a hydrostatic dynamometer developed and operated by the Hyatt Roller Bearing Co., are then posted at the test furrow where they are obtained. Knowing the power of the tractor, which is displayed

Tractors Make Hit in Kansas

on a sign carried by the machine, and the number of plow bottoms pulled, spectators can then refer to the test draft figures and make allowance, if necessary, for the condition of this part of the field. The average draft per bottom on Tuesday, the first day, was 710 lb. However, the draft varied widely over various parts of the field, some spots being almost stony hard and very dry and other parts being quite sticky.

The character of the soil is quite different from that in Texas and moldboard plows are used almost exclusively. It is admitted that better results might be obtained, at least insofar as the tractors are concerned, if disk plows were used, but Kansans are wedded to moldboards and they are used in the demonstration for this reason. In Texas it is almost impossible to use a moldboard because it will not scour, due to the sticky soil.

Value of Deep Plowing

Does Kansas need the tractor? Will the tractor prove a success in Kansas? These two questions are perhaps best answered by referring to the work done a year ago in the demonstration. But first let us examine conditions in Kansas up to about a month or two ago. There had been exceedingly heavy rains, so heavy in fact that in the great wheat belt the land was left soggy and entirely full of water. This naturally retarded the wheat. Subsequently there has been a month-long drougbt which has dried out that water very quickly and left the ground very hard. The net effect has been that whereas Kansas had a banner year last year, getting an average of nearly 30 bu. of wheat to the acre, this year's average is expected to be between 6 and 9 bu. an acre.

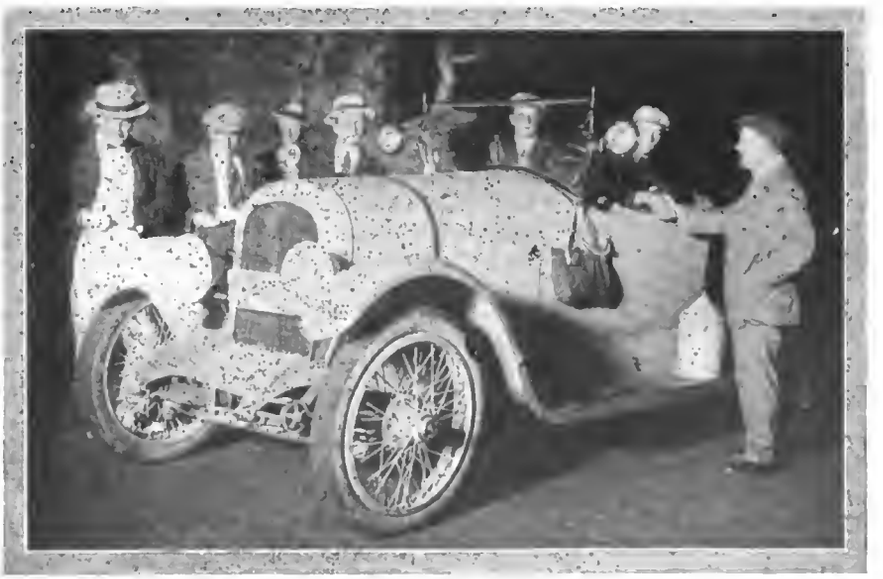
Now examine into what the tractors did last year.

The field that was plowed last year in the demonstration already has yielded an average of 24½ bu. of wheat to the acre as against the figure of 6 to 9 bu. for adjoining fields.

What better argument could be wanted for the genuine need of the tractor in Kansas? Why this great difference, you say? Briefly stated, the reason is deeper plowing made possible by the tractor.

The Kansas farms which this year are yielding only between 6 and 9 bu. of wheat per acre were plowed only between 5 and 6 in. deep last year. The demonstration field that has given a crop of 24½ bu. to the acre was plowed to a depth of 9 to 10 in.

In short this has proved a great object lesson on tbe benefits of deep plowing in Kansas. It has shown farmers and dealers that deep plowing not only provides for excessive rain by permitting the ground to soak it up, but that it provides equally as well for drought by permitting the ground to give up this stored moisture when it is needed. Not all land can be economically plowed as deep as this. Where there is a layer of clay beneath the top soil it may prove detrimental to throw this up over the good soil. For example, the United States Department of Agriculture experimental station in Texas has demonstrated that 7 in. is about the proper depth for Texas. This department has compiled figures on nearly every farmed area in the country and the figures are easily available. But they are not always as easily lived up to unless the



The record-breaking Marmon. Left to right—H. H. Wagner, Binghamton Motor Car Co.; A. G. Faulkner, Los Angeles agent; Dr. Brown, Philadelphia; Arthur Schaefer (former N. Y. Giant baseball player); J. W. Newman, mechanic; Fred Barbour, driver; and F. E. Moskovics, commercial manager Nordyke & Marmon Co.

plowing is done with a practical tractor.

This city has been admirably chosen as the scene of the Kansas demonstration. Reno county is virtually the center of the great Kansas wheat belt. Within a circle having a radius of 75 miles and having its center at Hutchinson there is grown fully 65 per cent of the Kansas wheat production and 42 per cent of its corn. Also, one-third of the population of the State is in this area.

Reno county itself last year averaged between 20 and 30 bu. of wheat to the acre but this year the average will fall below 9 bu. in the estimation of crop experts. Farther west in the State, however, conditions are more nearly normal. Corn has suffered to such an extent that the crop will be from one-third to one-half of last year's.

Kansas is one of the few States which have made a census of their farm tractor users, though the figures are not strictly accurate owing to the difficulty of getting returns and because of the constant influx of new machines. The census shows that Kansas had about 2500 tractors at the first of this year but that number may have increased to 3500 and in the estimation of quite a few probably has done so.

It is difficult to estimate, or even to guess, how many tractors Kansas will absorb this year. What with poor crops and poor tractor sales last year dealers are not inclined to be optimistic.

Gasoline is used here to a slightly greater extent than was the case in Texas. Strictly speaking, however, it is not gasoline, but is better styled naphtha. Gasoline here is defined as having a gravity higher than 58. Gasoline tractors, however, are burning fuel which measures about 57.3 Baumé. This fuel costs 18.3 cents per gallon. Kerosene measures about 44 and is selling this week for 7.3 cents.

—

(*Continued from page* 167)

being taken. Officers of the company say that the prospects for the new season are better than they ever were and they believe 1917 will show a similar big increase in business, as did the present year compared to the previous one.

Collins Elected to Board

NEW YORK CITY, July 28—At a meeting of the board of directors of the General Motors Co. yesterday R. H. Collins, Flint, Mich., was elected a director to fill the vacancy caused by the resignation of Thomas Neal of Detroit. Mr. Collins has been general sales manager of the Buick Motor Co. Mr. Neal, who was also a vice-president of the General Motors Co., withdrew because it is said he desires to give all his attention to the Signal-Commerce Motor Truck Co., of which he became the active head when the Signal and Commerce companies were merged.

There have been quite a number of changes on the board of directors of the General Motors Co. during the past few months. At the present time the members of the board are the following: F. L. Belin, J. H. McClement, W. C. Durant, J. S. Haskell, L. G. Kaufman, Charles S. Sabin and A. H. Wiggin, New York City; Pierre S. du Pont and J. J. Raskob, Wilmington, Del.; W. L. Day and F. W. Warner, Pontiac, Mich.; W. C. Leland, Detroit; A. G. Bishop, W. P. Chrysler, R. H. Collins, C. S. Mott and C. W. Nash, Flint, Mich.

—

Ford Prices Cut 18%

(*Continued from page* 167)

April, 1913. At the present time the facilities permit of a daily output of 2000.

In 1912 the prices of the Ford cars were $600 for the touring car and $525 for the roadster. These were reduced to $550 for the touring and $500 for the roadster on Aug. 1, 1913. On the first of August, 1914, the Ford company announced another cut in prices and the touring car was brought down to $490 and the roadster to $440. In addition it was promised that should the company sell 300,000 cars before Aug. 1, 1915, a profit-sharing rebate would be given to each purchaser. As this production was more than reached, the Ford company paid out over $15,000,000 in rebates to car buyers, or $50 per car. In June of 1914, a big cut on Ford parts was made, prices for these being lowered from 10 to 25 per cent.

Starting with Aug. 1, 1915, the prices of Fords were cut another $50 per car, bringing the touring model to $440 and the roadster to $390. These prices have prevailed up to the present time and will be changed when the new announcement takes effect on Aug. 1. There was a mid-year reduction on Ford closed cars in November, 1915, which materially lowered the prices on some of these models. The sedan, which was formerly $975, was cut to $740. This price has again been lowered and is now $645. To put the reductions for the last four years in a nutshell, the touring car which was priced at $600 in 1912 will sell for $360 for 1916.

Canadian Ford Prices Lower

FORD, ONT., July 31—The Ford Motor Co. of Canada, Ltd., has reduced the price on its 1917 cars from $5 to $35. The new prices which go into effect Aug. 1 are as follows: Runabout $475 instead of $480; touring car, $495 instead of $530; coupelet, $695 instead of $730. The town car and the sedan will sell respectively at $780 and $890 as during the present season. The price of the chassis alone will be $450. Officials of the company say that the fiscal year ending to-day has been much better than they had anticipated. For the season 1917 the output is expected to be about 60,000 cars, or at least 20,000 more than were built and sold during the fiscal year 1916.

—

Elgin Capital Now $3,500,000

CHICAGO, ILL., Aug. 2—The Elgin Motor Car Corp., this city, has increased its capital from $1,000,000 to $3,500,000. This is in line with the concern's policy of expansion. The Elgin corporation recently took over the New Era Motor Car Co., Joliet, Ill.

—

Victor Rubber Capital $750,000

SPRINGFIELD, OHIO, July 28—At a recent meeting of the board of directors of the Victor Rubber Co., this city, it was voted to increase the capital stock of the company from $300,000 to $750,000 in order to provide facilities to double the production of pneumatic tires.

A 100 per cent stock dividend on the common stock was declared, this having been made possible by the company's earnings last year.

—

Caples Goes to Overland

TOLEDO, OHIO, July 29—R. C. Caples has resigned as general traffic manager of the Western Maryland Railway to become associated in a confidential position with John N. Willys, president of the Willys-Overland Co., this city.

—

Pullman Dealers in Convention

YORK, PA., July 29—Wholesale and retail dealers of the Pullman Motor Car Co., from this country and abroad to the number of 125 assembled here this week to attend the annual dealers' convention July 27, 28 and 29. Prospects for 1917 were discussed and the new Pullman models were thoroughly examined. Special entertainment features were provided by the Pullman Motor Car Co. and the York Motor Car Co. H. W. Hayden, Pullman general manager, presided at the business sessions.

—

Swinehart Recalled to Republic Plant

YOUNGSTOWN, OHIO, July 29—B. C. Swinehart, for the past 3 years manager of the Philadelphia branch of the Republic Rubber Co., has been recalled to the main factory of the Republic company at Youngstown, where he will take charge of the solid tire sales.

H. D. Worthington, assistant manager of the Philadelphia branch, succeeds Mr. Swinehart as manager.

Factory Miscellany

New Building for Lee Tire—The Lee Tire & Rubber Co., Conshohocken, Pa., has placed a contract for another building at its Conshohocken plant.

On the general floor of this building will be installed the necessary large dipping tanks used in the manufacture of rubber gloves, etc., the object being to take this part of the industry out of the main plant and provide considerable additional space for the manufacture of tires. By the erection of a separate building somewhat removed from the others the serious fire menace caused by the gasoline-laden atmosphere around the dipping tanks will no longer threaten more than the contents of this one structure.

The building measures 80 by 120 ft. in plan and will for the present contain but two stories. The foundations and reinforced concrete columns on the first floor are designed, however, for several additional stories.

To Concentrate on Accessories—The Peters & Heron Dash Co., Columbus, Ohio, engaged in the manufacture of dashes and other vehicle parts, has sold its dash business to the McKinnon Dash Co. of Buffalo and Troy, Ohio, for the purpose of devoting its entire attention to the manufacture of dimmers, robes, top covers and other accessories.

Bowser Mutual Benefit Assn. Formed—The S. F. Bowser Oil Tank & Pump Works of Fort Wayne, which some time ago promised its employees $10,000 to start a mutual benefit association when the plans for the organization had been made by the employees, made good its promise in a most substantial way when 10,000 silver dollars were turned over to the treasurer of the newly-organized Bowser Mutual Benefit Assn. The plan is $40 per month will be paid a member unable to work on account of illness or accident; survivors of an employee who dies will receive $125 for burial expenses and $25 per month for 3 years; old age pension will be $30 per month.

Jackson-Church-Wilcox Adds—The Jackson-Church-Wilcox Co., Saginaw, Mich., manufacturer of the Jacox steering gear, has announced an addition to its plant on North Hamilton Street, work on which will begin at once.

The new addition, which will be of brick, one-story, and 120 by 208 ft., will practically double the output of the concern. Eight hundred men will be given employment in the enlarged plant, which in its entirety will cover nearly two city blocks. With the proposed addition the next year's production of the company is expected to reach the half-million mark.

Sparks-Withington Doubles Capacity—Additions to the plants of the Sparks-Withington Co., Jackson, Mich., maker of the Sparton horn, are well under way and when completed will practically double the size and production possibilities of the big factory. Paralleling the older plant, the new factory is 70 by 334 ft.; half being two stories and the rest one story. It is to be made of white brick and steel, and will be modern in every way. Much of the additional space will be devoted to radiator manufacture, it is stated. At present the factory is behind in its orders, though working 24 hr. a day.

Electric Storage Battery Adds—The Electric Storage Battery Co., Philadelphia, Pa., has bought forty-four dwellings near Nineteenth Street and Allegheny Avenue. The main office and plant are on the south side of Allegheny Avenue and Nineteenth Street. It is understood that several large additions to the company's plant will be built in the near future on the property acquired.

Robinson Machine Buys Ground—The Robinson Machine Co., Ecorse, Mich., has purchased a piece of ground west of Mill Street, where a factory will be erected to manufacture its new Truckford, for converting a Ford car into a 1-ton truck. Fifty men will be employed.

Ford Service in Yonkers—The Ford Motor Co., Detroit, Mich., will build a $100,000 service plant at South Broadway, Herriot and New Main Streets, Yonkers, N. Y. The structure will be used as a distribution center.

The Automobile Calendar

ASSOCIATIONS

Aug. 15—Metropolitan Section, S. A. E. Meeting at Automobile Club of America. Subject, "South America."

Aug. 28-Sept. 1—Milwaukee, Wis., Booster Tour of Milwaukee Automobile Dealers.

Sept.—Indianapolis. Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.

Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.

Dec. 2-9—Electricians' Country-wide Celebration.

CONTESTS

Aug. 5—Tacoma Speedway Race, Tacoma Speedway Association.

Aug. 11-12—Pikes Peak, Col., Hill Climb, Pikes Peak Auto Highway Co.

Aug. 12—Portland, Ore., Track Race, Hiller-Riegel Co.

Aug. 18-19—Elgin Road Race, Chicago Auto Club.

Aug. 26—Kalamazoo, Mich., 160-Mile Track Race.

Sept. 1-2—New York, N. Y., Sheepshead Bay Speedway, 24-Hour Race, Trade Racing Assn.

Sept. 4—Elmira, N. Y., Track Race, Elmira Auto and Motorcycle Racing Assn.

Sept. 4—Cincinnati, Ohio, Speedway, Cincinnati Speedway Co.

Sept. 4—Newark, N. J., Track Race, Olympic Park, Racing Assn.

Sept. 4—Des Moines Speedway Invitation Race. Limited to six entries.

Sept. 4-5 — Spokane, Wash., Track Race, Inland Auto Assn.

Sept. 9—Indianapolis Speedway Race.

Sept. 16—Providence Speedway Race.

Sept. 18—North Yakima, Wash., Track Race, Washington State Fair.

Sept. 29—Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.

Sept. 30 — New York City, Sheepshead Bay Speedway Race.

Oct. 7—Philadelphia Speedway Race.

Oct. 7—Omaha Speedway Race.

Oct. 14 — Chicago Speedway Race.

Oct. 19—Indianapolis, Ind., Race, Indianapolis Motor Speedway.

Oct. 21 — Kalamazoo, Mich., Track Races, Kalamazoo, Motor Speedway.

Oct. 22-23—Los Angeles, Cal., Commercial Car Reliability Tour.

Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

GOOD ROADS

Sept. 6-7—St. Paul, Minn., Good Roads Congress, Auditorium.

SHOWS

Aug. 2-9—Hollywood and West End, N. J., Show, Atlantic Exhibition Co.

Sept. 2-9—Cleveland, Ohio, Show, Industrial Exposition and Fair, Edgewater Park.

Sept. 2-9—Columbus, Ohio, Fall Show, Ohio State Fair, Columbus Automobile Show Co.

Sept. 4-8 — Hartford, Conn., Show, Connecticut Fair Assn.

Sept. 4-11 — Indianapolis, Ind., Show, Indiana State Fair, Indianapolis Automobile Trade Assn.

Sept. 10-16 — Milwaukee, Wis., Show, Wisconsin State Fair, Machinery Bldg.

Oct. 14-31 — Dallas, Texas, Show, State Fair.

Jan. 6-13, 1917—New York City, Show, Grand Central Palace, National Automobile Chamber of Commerce.

Jan. 13-20 — Montreal, Que., Show, Montreal Automobile Trade Assn.

Jan. 27-Feb. 3, 1917 — Chicago, Ill., Show, Coliseum, National Automobile Chamber of Commerce.

Feb.—Newark, N. J., Show, First Regiment Armory.

Feb.—St. Louis, Mo., Show, Auto Manufacturers and Dealers' Assn.

TRACTOR

July 24-28 — Hutchinson, Kan., Tractor Demonstration.

July 31-Aug. 4—St. Louis, Mo., Tractor Demonstration.

Aug. 7-11—Fremont, Neb., Tractor Demonstration.

Aug. 14-18—Cedar Rapids, Iowa, Tractor Demonstration.

Aug. 21-25—Bloomington, Ill., Tractor Demonstration.

Aug. 28-Sept. 1—Indiana Tractor Demonstration.

Sept. 4-8—Madison, Wis., Tractor Demonstration.

Sept. 11-16 — Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.

The Week in the Industry

Wisconsin News Items—E. A. Hatfield, for 5 years assistant secretary and director of sales of the Bain Wagon Co., Kenosha, has resigned to become the leading spirit in the organization of the Mississippi Valley Motor Car Co., with headquarters in St. Louis. The company will act as distributor of Oakland cars in the Mississippi Valley, the territory including the states of Louisiana, Mississippi, Arkansas, southern Illinois, eastern Missouri, western Kentucky, Tennessee and some other tributary territory. Associated with Mr. Hatfield in the project is F. W. A. Vesper, St. Louis, who has been Buick distributor in St. Louis and vicinity for some time.

The University Supply Co., 468 Jefferson Street, Milwaukee, Wis., has been appointed distributor of Hardman tires. H. B. Gehring is general manager.

It is reported on excellent authority that the Overland Wisconsin Co., Milwaukee, owned by George W. Browne, and state distributor of Overland and Willys-Knight cars, will soon establish a large branch house and service station for the benefit of the northern Wisconsin territory, at Wausau, Wis. The company has taken an option on a site, 60 by 120 ft., at First and McIndoe Streets, Wausau, and proposes to erect a 4-story building of that size. The investment will be about $50,000. It is stated that W. R. Stelling, Fort Atkinson, Wis., will have charge as branch manager.

The Auto Service & Supply Co., Milwaukee, specializing in Vesta batteries, has moved to new and larger quarters at 207 Fourth Street. Carl Aken has taken a financial interest and is vice-president and secretary of the concern.

The Marion Sales Co., Milwaukee, representing the Marion in Wisconsin, has granted the Stutz Motor Car Co. of Milwaukee the right to retail Marion cars in the city of Milwaukee and environs.

The Diener-Nelson Co., 188 Eighth Street, Milwaukee, distributor of the Haynes and Grant Six, has taken possession of its new quarters in the Hippodrome building, 612-623 Wells Street.

The Auto Service & Supply Co., 207 Fourth Street, Milwaukee, announces that Carl Aken, Jr., has been placed in charge of its storage battery service department. Mr. Aken has had several years of experience with storage batteries and formerly conducted the Aken Battery Co., Milwaukee, representing the Gould battery. The Auto Service & Supply Co. is distributor in a large territory of Vesta batteries and other products.

Trade Happenings

The J. H. Ryan Motor Truck Co., Madison, Wis., state agent of the Diamond T truck, has established a branch salesroom and service station at 495 Broadway, Milwaukee. The entire state territory will actually be handled from the new Milwaukee branch, and J. H. Ryan has moved from Madison to Milwaukee to take personal charge.

The Western Motor Supply Co., 408 Jefferson Street, Milwaukee, wholesaler, jobber and retailer of supplies and accessories and Quaker tires, has added a storage battery department, in charge of Charles Warner. The new department will make a feature of U. S. L. batteries and systems. Mr. Warner has specialized in electric storage battery work for more than 6 years.

Philadelphia Items—E. W. Burnshaw, Jr., recently in charge of the wholesale department of the Girard Automobile Co., 2314 Chestnut Street, distributor for Peerless cars and trucks, has been promoted to general manager of the company.

W. P. Herbert, Chandler dealer at Broad and Race Streets, has incorporated the business with the addition of W. G. Herbert and R. W. Cook. Mr. Herbert is president; Mr. Cook, vice-president and general manager, and W. G. Herbert, secretary and treasurer.

Mountain Trade — The Automobile Sales Corp., Denver, Studebaker and Franklin distributor for Colorado and Wyoming, has moved from 1509 Cheyenne Place to 1520 Broadway.

The C-B Auto Service Co., Denver, has opened a Moore distributing agency for Colorado at 1439 Cleveland Place.

The Maines-Hough Motor Co., Denver, Chevrolet, Monroe and Mitchell distributors for Colorado and Wyoming, with sales and service station at 439 Broadway, has given up the Mitchell and is handling the other two lines exclusively.

J. M. Scoville, Fort Morgan, Col., has secured the Chalmers agency for Morgan County.

The Denver Tire Service, Inc., Denver, United States tire distributor for Colorado and Wyoming, with salesroom and service station at 215-217 Sixteenth Street, is now managed by J. A. Payment, formerly manager of the Quick Service Tire Co., distributor of Quaker tires.

The George H. Estabrook Auto Co., Denver, Briscoe and Hollier distributor for Colorado and Wyoming, has secured the McGraw tire distributing agency for the same territory. The general salesroom is located at 1646 Broadway.

The Chamberlain-Woods Motor Sales Co., Denver, the new firm name of the Hupp Motor Sales Co., Hupmobile and Locomobile distributor for Colorado and Wyoming, has added the Dort distributing agency for the same territory.

F. P. Van Sickle, Denver, has opened a Colorado, Wyoming and Utah distributing agency for the Aurora demountable truck at 1608 Broadway.

Willys-Overland, Inc., Denver Branch, Denver, is the name of a factory sales and service branch just opened at Fifteenth Street and Cheyenne Place to handle the Rocky Mountain territory. The new concern will be managed by C. C. Eib, formerly general manager for J. W. Leavitt & Co., San Francisco, Overland and Willys-Knight distributor for the entire Pacific coast. The new branch will supply all of Colorado and part of Wyoming, Utah, Idaho and New Mexico.

H. G. Wimbush, Denver, formerly vice-president of the Motor Sales Co., a Ford time-payment concern, has secured the Mitchell distributing agency for Colorado and Wyoming and opened a salesroom in the new Fisk Building, Broadway and East Twelfth Avenue.

The Colorado Motor Car Co., Denver, Col., Saxon and Reo distributor for Colorado and Wyoming, has given up the Cole and Saxon and is arranging to move the Reo headquarters from 1520 Broadway into another location.

The J. S. Morrison Auto Co., Denver, Oakland distributor for Colorado and Wyoming, has taken on the Allen distributing agency for the same territory. The salesroom is at 1528 Broadway

The Mid-West Auto Sales Co., Denver, King and Wichita truck distributor for Colorado and Wyoming, has given up the King and secured the distributing agency for the same territory for the Paterson light six and the Ross eight, and the Colorado territory for the Twin Bed trailer.

The Quick Service Tire Co., Denver, local agency for Quaker tires, which was formerly managed by J. A. Payment, is now handled directly by the Boss Rubber Co., 1548 Broadway, which has added the Quaker to its Kelly-Springfield tire distribution for Colorado, Wyoming and New Mexico.

Other countries	40,053

WASHINGTON, D. C., Aug. 8—The United States exported 77,496 automobiles and motor trucks during the 1916 fiscal year which ended June 30. These cars represent a total value of nearly $100,000,000, or, to be precise, $97,464,381. During the 1915 fiscal year 37,876 motor vehicles worth $60,254,635 were exported.

In spite of the war Europe continues to be the heavy consumer of U. S. A. automobiles, buying, all told, 35,280 during the year, or 2.7 per cent of the total output. Canada has been the second greatest customer, purchasing 10,403 machines, which is more than twice as many as she bought from us during the preceding year.

Australia as a continent takes third position in purchasing our cars, buying during the year 7378. So steadily has the Australian business developed during the past year that for the first time the government has given a separate classification to it. Heretofore Australian figures were included with those of Asia and Oceania.

(*Continued page* 247)

Reo Six Price $100 Lower

LANSING, MICH., Aug. 5—The Reo Motor Car Co., this city, has lowered the price of its six-cylinder car $100 and has added two inclosed bodies to its line for 1917. The six now sells for $1,150, and like the four, which still sells at $875, it is unchanged except for minor refinements. The new bodies are an inclosed type for the four with which it sells for $1,025 and a sedan body for the six, this car listing at $1,750.

The Reo Motor Truck Co. has reduced the price of its 1500-lb. model to $1,000, a decrease of $75 and is continuing its 2-tonner at $1,650, the same price as for 1916.

Ford 1-Ton Worm Drive Truck

200,000 Output Planned for Vehicle to Sell at About $500

DETROIT, MICH., Aug. 5—Some time during next fall the Ford 1-ton worm-drive truck is expected to be ready for delivery. Demonstrators are expected to in the hands of Ford distributors or agents within the next few months.

What the price will be at which the Ford Motor Co. will sell this truck, officials claim not to know themselves, as it has not yet been decided; they say. It was stated from other sources that the price will be around $500, possibly a bit lower than this, and that it is expected that 200,000 of these trucks will be made during the first year.

Gasoline Price Down 1 Cent

Lower Rates Prevail in Many Sections Due to Cheaper Crude

NEW YORK CITY, Aug. 7—Gasoline is 1 cent per gallon lower all over the country. Reports from such scattered points as Dallas, Tex.; Columbus, Ohio; Boston, Mass.; Cleveland, Ohio; and New York City, all bear out the reduction. The primary cause is the fall off in crude prices which have dropped 5 to 10 cents a barrel in the past week. Chicago and St. Louis report the only exceptions to the general reduction.

For the first time in several years Dallas, Tex., is enjoying 18 cent gasoline, prices having been all the way up to 22. Throughout the middle West, including Ohio, Indiana, and Illinois and in New York and neighboring States, the price of gasoline is 23 cents per gallon in place of 24 last week. In Boston prices are 1 cent higher, being 24, a reduction of 1 cent from the 25 charged for the past few months.

The Gulf Refining Co. made the reduction general and the Standard Oil Co. reduced only in New York, Brooklyn and Connecticut, the S. O. New Jersey price remaining 22 cents. The Texas Co. has not made reductions in New York, Brooklyn or Connecticut as yet though the New Jersey price has been reduced 1 cent to 22 cents. The Crew-Levick Co. has not changed its figure of 24 cents. Retail prices vary from 24 cents to 26 cents.

In Boston, the Standard Oil Co. yesterday reduced the wholesale price 1 cent to 24 cents, the retail price being 26 cents.

Chicago reports no change in price and no immediate prospect of a change.

The reduction is ascribed to the

533,921 Fords Built in 1 Year

225,708 More Made in 1916 than in 1915—Worth $235,000,000

FORD HISTORY IN FIGURES

Total output 13 years, 1,406,997 cars

Ford Motor Co., organized June 16, 1903.
Employed 311 men first year.
Capital stock in 1903, $100,000.
Capital stock in 1916, $2,000,000.
Number of men employed in 1916, 31,035.

Year	Cars Made and Sold	Increase or Decrease	Daily Average
1903-1904.	1,708	.....	5
1905.....	1,695	— 13	5
1906.....	1,599	— 96	5
1907.....	8,423	+ 6,824	28
1908.....	6,398	— 2,025	21
1909.....	10,607	+ 3,209	35
1910.....	18,664	+ 8,057	62
1911.....	34,466	+ 15,802	115
1912.....	68,544	+ 30,078	228
1913.....164,452		+ 95,908	545
1914.....248,307		+ 83,855	827
1915.....308,213		+ 59,906	1,027
1916.....533,921		+225,708	*1,816

Largest one-day output, 2,430 cars, Feb. 29, 1916.
Sales value of 1916 output, minimum, $235,000,000.
Sales value of 1903-1904 output, less than $2,500,000.
Expected output of 1917, minimum, 750,000 cars.
The Ford Motor Co., in June, 1915, announced that it will increase its capital stock to $100,000,000, but as the laws of the State of Michigan do not allow such a large capitalization and as the Ford company did not want to incorporate in another state, the present capital stock of the company is still $2,000,000.

*The average daily output is based upon 300 working days, except for 1916, where the actual number was furnished by the company as 296.

DETROIT, MICH., Aug. 7—Ford built 533,921 cars during the 12 months beginning Aug. 1, 1915, and ending July 31, 1916, the company's fiscal year. This is 225,708 more Fords than were made during the 1915 fiscal year, when 308,213 cars were completed.

There were 296 actual working days at the Ford plant during which the 1916 output was turned out, so that the number of cars made daily was 1,816 as compared with 1,027 in 1915 and 827 the previous year. Many a day during the past season more than 2000 cars were made, the record day being Feb. 29, when 2430 cars were completed and shipped.

Figured in dollars, the 1916 Ford output represents a minimum of $235,000,000. It is probably several millions higher, but this figure is conservative.

Including all models made since starting to make Fords the total number of cars built and sold by the Ford Motor Co., to July 31, 1916, was 1,406,997.

Up to a few years ago a large percentage of the Ford production came from the Detroit plant. In recent years the Detroit plant has been used especially in making the parts for the assembling of the cars and the assembling plants throughout the country were the actual builders of the cars. In other words, most of the Ford cars are now assembled in the assembling plants from the parts made here in Detroit. Within a year or two at the most not a single complete Ford car will be made here at the Highland Park works.

The principal reason why Ford is able to sell his cars at such low prices is because every year the production is placed upon a greater efficiency basis. There are many instances, where according to a Ford shop foreman, men increased their output 100 per cent within 2 years or less, on the same machine, simply by working on a more systematic basis.

There is no doubt even now, a year ahead, that for the season 1917 Ford prices will again be reduced in a surprising way. Officials will not speak of this, but the fact that the big plant is expected to be trebled within the next few months, that probably 15,000 to 20,000 men will be added to the working force here sometime this coming winter, that most all the machinery and tools for the plant additions have been ordered long ago and part already delivered, or at any rate stored, seems to make the suggestion of a Ford dealer that the car will soon be selling at $250 quite possible.

Canadian Ford Ships 32,646

FORD, ONT., Aug. 5—Nearly double the amount of Ford cars was shipped from the Ford Motor Co. of Canada in the fiscal year ending July 31 compared with the previous year. Total number shipped in the 1915-1916 year was 32,646, March being the greatest month with 4500 cars from the Ontario plant. The largest single day's output was on March 29, when 312 cars were shipped. It is estimated that the shipments for the next year will reach 60,000.

Durant Denies $700 Eight Report

NEW YORK CITY, Aug. 8—W. C. Durant, president of the Chevrolet Motor Co., has gone on record as denying the intention of the company to put out a $700 eight. The report was published widely in the press of the country and it was also stated that a big cut in price was to follow the Ford announcement. This has also been denied categorically.

It is well-known that the Chevrolet company has been developing an eight-cylinder car for some months, and no denial of this has been made by the company. It is well understood, however, by those who have followed the plans of the company closely that this will be priced at considerably above the figure given and very likely at from $1,100 to $1,200. The present prices of the Chevrolet cars are $490 for the little four and $750 for the larger one.

W. C. Sills, treasurer, states that the company had on hand Aug. 1 cash and securities in excess of $25,000,000.

French Adopt Uniform Carbureter

Army Fits American Trucks with Claudels—Soldier Drivers Waste Fuel

PARIS, Fr., July 12.—Dissatisfied with the gasoline consumption of many American trucks, the French army automobile authorities have decided to adopt a uniform type of French carbureter. The first batch of trucks to be changed comprise 700 Reos; these will be followed by all the Jefferies, then by Pierce-Arrows. For more than 6 months there have been complaints that gas consumption was too high. This was due, in many cases, as the American factory representatives in France were able to prove, to incorrect carbureter setting and poor driving. Nevertheless, the authorities were of the opinion that considerable economy could be effected in the amount of gas consumed by army trucks.

One French carbureter manufacturer offered to replace the whole of the carbureters on American trucks with his instruments and accept as payment half the price of gasoline saved. This offer was not accepted, but the authorities ordered careful records to be made of mileage and consumption for every truck and convoy in army service. These statistics have been compiled over a period of several months, and are the most elaborate of any got together by any truck users. The comparative diagrams show the gas consumption for a given period of all Pierce-Arrow, Packard, Velie, White, Jeffery, Kelly and Reo trucks. A feature of these diagrams is the wide divergence between trucks of a different make but a common load capacity. A more curious case is that for one of these makes the gas consumption of the 5-ton model is only a fraction higher than that of the 3-ton type. This is attributed to poorly proportioned gear ratios.

Claudel Wins Competition

When this data had been secured, the authorities held a competition among French carbureter manufacturers. Three firms took part, Claudel, Zenith and Solex. The winner was Claudel, who was given the initial order to replace the carbureters on the Reos. Statistics showed that the 3½-ton Reo was consuming 52 liters per 100 kilometers (4.52 miles to the gallon). With the Claudel and other European carbureters the figures given out are 30 to 32 liters per 100 kilometers (32 liters are equivalent to 7.36 miles per gallon). Results with the 3½-ton Sterling were practically the same, the consumption being dropped from 51-52

I. A. L. Barred from U. S. Mails

I. A. L. Tire Co. Also Included In Charge of Using False Pretenses

WASHINGTON, D. C., Aug. 3—The International Automobile League, Inc., and the International Automobile League Tire Co., of Buffalo, N. Y., have been barred from the use of the mails by a fraud order issued to-day authorized by Postmaster-General Burleson. It is charged that A. C. Bidwell is engaged in obtaining money through the mails under false pretenses under these names. Bidwell was arrested in June by Federal authorities upon the complaint of Richard H. Lee, of Cleveland, chairman of the legislative committee of the American Automobile Assn., who charged that the league was obtaining money in exchange for services it was unable to render, automobile owners, garagemen, car and accessory dealers being the victims of this policy.

Agents of the league have been arrested on the charge of obtaining money under false pretenses in several sections of this country and also in Canada.

The hearings on this case before the solicitor for the Post Office Department began on March 25 and consumed in all 46 days. In his memorandum to the postmaster-general with reference to this case, the solicitor says:

"The International Automobile League is a corporation practically all of the stock of which is owned by one Alfred C. Bidwell, its president, by whom the corporation is absolutely controlled. Under his own name as president he signs letters, receives mail, and uses the post office establishment substantially to the same extent as he does under the name of the corporation. The league undertakes 'to furnish each member automobile tires and supplies, which it may be able to obtain, at dealers', jobbers', or manufacturers' prices, to maintain without expense to the member a home office, and to mail quotations from time to time.' Membership, so-called, costs $10 per year in advance where the member owns but one automobile, and $5 per year additional in advance for each automobile in excess of one owned.

Flanagan Heads Pyrene Sales Dept.

NEW YORK CITY, Aug. 7—The Pyrene Mfg. Co. has appointed a 25-year-old man as sales manager. T. F. Flanagan has succeeded to the chair just left vacant by C. L. Allen, who is now the company's president. Four years ago Mr. Flanagan was business manager of a college paper. Following his graduation from Trinity College in Hartford, Conn., he entered the service of an advertising agency and later became advertising manager of the C. J. Tagliabue Mfg. Co. He remained there as sales manager until 14 months ago, when he entered the Pyrene company as assistant advertising manager.

Chase To Add 3-Tonner

SYRACUSE, N. Y., Aug. 5—The Chase Motor Truck Co. will shortly announce Model X, a 3-ton, worm-drive job to retail at $2,800, equipped with cab. This new model will round out a line of trucks of ¾, 1, 1½, 3 and 3½ ton capacities.

Hollier To Add a Six

CHELSEA, MICH., Aug. 8—The Lewis Spring & Axle Co., which has heretofore made only the Hollier 8, will build a six for the coming season in addition to the eight. It will sell at $1,085 with either a five-passenger touring or a four-passenger roadster body. It will have left drive, cantilever rear springs, floating axle, valve-in-head block motor, 3 by 1¼ in., 116-in. wheelbase, wood wheels and 33 by 4 in. non-skid tires.

Adrian Castings Plant Burned

ADRIAN, MICH., Aug. 3—The Adrian Steel Castings Co. was practically all destroyed by fire to-night, caused by spontaneous combustion. A new plant is to be erected at once.

Chalmers Assets Gain 50 Per Cent

DETROIT, MICH., Aug. 3—Chalmers assets have increased by 50 per cent in the last year. Preliminary statements made regarding business during the 1916 fiscal year which ended June 30 show a gain in total assets of $4,857,274, the total now being $13,051,538.

The surplus totaled $2,066,673.88 instead of $1,010,422 in 1915. Cash on hand and in banks showed a decrease totaling $564,746.64 instead of $1,173,135.

Among the assets, plant and equipment and buildings, machinery, etc., are given as $3,184,278.01, as compared with $2,215,813 last year. Investment in stocks shows a total of $409,740.53; investment in sales branches, $120,961.80.

Among the current liabilities, notes payable, merchandise accounts, deposits on dealers' contracts and accrued accounts, total $4,268,006.53. Liabilities to stockholders total $2,000,000 of issued preferred stock, less $542,200 held for cancellation. The common stock totals $5,000,000.

Close Dealers in Mo. Tractor Show

Small Farms Present Difficulties and Scatter Demonstrations—Farmers Pay Cash

By S. P. McMinn
Staff Correspondent

ST. LOUIS, Aug. 4—With fifty-four tractors plowing Missouri soil, the third of the series of eight National Tractor Demonstrations was formally opened here on Tuesday morning in much the same manner as those at Dallas and Hutchinson. Tractor manufacturers and dealers, however, are not as optimistic regarding results to be obtained as they were at the two previous demonstrations. In this respect, however, it is pertinent to point out that these great tractor shows are far different from automobile shows. Contracts seldom are signed on the spot and for this reason it must necessarily be some time before the real good that has been done can be checked up.

For example, the Moline Plow Co. has but recently closed up some fifteen dealers as a result of the Hutchinson demonstration last week. And every one of these was for from three to twenty-five machines. Again, the C. O. D. Tractor Co. has just closed with the Western Farm Tractor & Supply Co. for the entire state of Kansas. The Wallis Tractor Co. has signed up with Piffer Bros., Denver, to handle the state of Colorado as a distributor. This company took an initial order of 100 machines and will pay cash for them.

Cash Deals a Feature

This cash proposition, by the way, is rapidly becoming the feature of the demonstrations. The newer companies in the tractor field, those that center all their activities upon the productions of tractors and make no other farm implements, are invariably making contracts which call for cash on delivery. And even the old-line implement manufacturers are now coming around to this way of doing business. Some have been conducting business in this way during only the past year and others are taking the step now for the first time. They reason rightly that if the farmer is willing and anxious to pay cash for his automobile, and if the newer members of the tractor family can extract cash from the distributor and the ultimate owner, there is no reason why they, too, should not do so.

Missouri is not what may be termed a great agricultural state—that is, judging by Minnesota and Iowa and the Dakotas

Victoria Street, Buenos Aires, on which are located the Overland agency and also the Bosch depot. This would make an ideal motor row for the Argentine capital. In the background can be seen part of the large Government building corresponding to the capitol in Washington, D. C.

This shows how many of the narrow streets in the older sections of Buenos Aires are being widened. The widening process is carried on generally on one side of the street. The large new building at the right is set back to the new street line with which all the houses on the block will eventually correspond

South America—III

Careful Planning and Good Business Methods Are Necessary in Entering the South American Market

By David Beecroft

IF you contemplate entering the South American automobile market you must go into it in a business way, with the determination to build up a business there whether it requires 5 years or 10 months. There is one big consideration you must carefully consider, namely, Are you prepared to stick? If you are not prepared to stick, then keep out of it, leave South America to others who are. Ability to stick is a prime essential of the automobile and accessory business in any of the South American countries.

Ability to stick presupposes that you are ready to spend a large amount of money in establishing your products in perhaps eight or ten of the best buying and distributing centers. Every U. S. A. merchant who has made a success of his South American business has done this. We have not been able to find a single exception. With every large U. S. A. firm now enjoying good business in Argentina, Brazil or the other countries, the business was primarily secured by a heavy original investment coupled with a determination to stick.

A dozen firms that have succeeded by such measures might be mentioned and they would include such household names as Remington, General Electric, Westinghouse, Ford, U. S. Steel, National Cash Register, Singer Sewing Machine, Standard Oil, Edison, International Harvester, Case, Fairbanks Morse, etc., etc. These all made heavy financial investments, these all sent their best men there to establish and look after the business, and to-day they are reaping the fruits of this wise discretion.

Every U. S. A. business man in Buenos Aires, in Rio de Janeiro, in Montevideo and other places is more or less disgusted with the tactics pursued by many of our firms when entering the South American market. Our firms have not gone with the apparent determination of establishing a permanent business, but rather with the hope of getting several original orders, making a good long profit out of them, and then casually picking up as much business as possible without building up a permanent organization to take control of the South American business.

Our U. S. A. citizens resident in these cities and managing large interests are all bitter in their denunciations of our business methods in relation to foreign trade. They are unanimous in declaring that it is much better for our firms not to try for the South American market at all, than to try in such a faint-hearted way. They all asked me to strongly urge any of our companies contemplating the South American field to keep away from it unless they are ready to enter on a permanent basis.

Every U. S. A. citizen resident in any of the above mentioned cities and in a score or more of other cities, and conducting the business of some U. S. A. house, unequivocably stated that his business is personally injured and the general reputation of U. S. A. goods injured by every one of our companies spasmodically dipping into the business, plucking off a few first-time orders and then leaving service and the supply of parts, etc. to care for themselves.

So much of this has been done that to-day our country has a reputation for such foreign trade tactics, and naturally many foreign business houses have not that confidence in our national trade character which they should have. It is true that U. S. A. firms with home reputations of high character, have not a foreign trade character in South America worth considering. It is all because they have not gone into the market with the thought of staying there, but rather entering it as a kind of experimental trade excursion. This our own people down there dislike heartily and this the South American equally dislikes.

Entering the South American field to stick should be carefully considered: There is no question of the possibilities of the field but there are a few potential factors that must be judiciously weighed and conditions must be shrewdly investi-

This illustration shows a new boulevard recently built in Santos, Brazil, and leads from the center of the city to the beach at a distance of 2 miles or more. On the beach is a 40-mile drive over hard sand where the going is practically as good as on the beach at Florida. Avenues of this nature are being built in many South American cities and suggest the hold that the automobile already has on the people. The next 10 years will see scores of boulevards of this nature built in practically every South American country

1—*This is a wide Belgian block business street in the suburbs of Buenos Aires. There are scores of streets of this width and well paved. They are ideal for motor car and motor truck use*
2—*Another wide Buenos Aires street paved with stone blocks and having double trolley lines in the middle*
3—*This street leads to a suburb of Buenos Aires in which one of the largest breweries is located. The street suggests possibilities of using motor trucks*
4—*Typical street of La Plata, Argentine, a seaport 65 miles from Buenos Aires and near which are located Armour & Swift packing plants. There are many cars and trucks in the city*
5—*A wide street in the outskirts of Buenos Aires and which is a part of the new highway from Buenos Aires to La Plata. The street is wide enough for eight automobiles abreast*
6—*Typical narrow street in the business section of Rosario, which is the second largest city in Argentine*

Typical modern, wide street in Buenos Aires which makes for ideal motor car and motor truck use. This picture must be compared with the one on the opposite page which shows the older form of narrow street in the city. Buenos Aires is making every fourth street wide like the one shown in this page in many sections of the city so that traffic conditions are being handled on a broader scale than in the majority of our North American cities. Buenos Aires has been building wider streets for 10 to 15 years and already much has been accomplished. This widening of streets is being pushed constantly and to-day you will see in a dozen different parts of the city examples of this work. The widened streets are generally well paved from curb to curb with Belgian blocks and the single row of ornamental iron poles in the center supporting the electric lights as well as the two trolley wires is good economy of street space and forms a natural division of the street, establishing passage for pedestrians

gated. If you go into this field you should go into it right and until you are ready to go into it right, we recommend that you remain out of it.

Going Into the Market Right

What does going into the market right mean?

FIRST:—You will have to establish a South American department in your own factory. Nearly every country in South America uses the Spanish language, excepting Brazil which is Portuguese and British Guiana which is English. You must then secure reliable Spanish typewriters, persons familiar with commercial Spanish. They must be more than mere typists, they must possess many essentials of business, they must have good common sense, as you must rely on them in many matters calling for good business judgment due to your not understanding Spanish. You cannot possibly conduct business in Argentina, Chile, Uruguay, Peru, Bolivia and other South American countries without such a home equipment. You must have a typewriter machine with a keyboard intended for the Spanish language.

If you do business in Brazil and you cannot afford to go into South America without going into the Brazilian market, then you must equip yourself similarly with regard to the Portuguese language. There is great commercial rivalry between Brazil and Argentina. They watch each other like Ancient Rome watched Ancient Carthage. When Brazil gives an order for a new warship, Argentina immediately places an order for as large a one. When Argentina adds to its army Brazil follows suit. With this relationship existing you can readily see that it will be exceedingly unwise business policy to write a letter in Spanish to a business house in Brazil or to send one in Portuguese to a business house in Argentina. You must fit up with both Spanish and Portuguese.

SECOND:—You must be prepared to go into the field with catalogs in Spanish for certain countries and Portuguese in Brazil. The same catalog will not do for both countries, but the same Spanish catalog that you use in Argentina will do for every other Spanish country in South America as well as islands in the West Indies and countries in Central America where Spanish is the prevailing language.

It is essential to have Spanish and Portuguese catalogs. You would not try to sell cars in the U. S. A., Canada or England without catalogs in English. Your dealers demand catalogs. The people in Argentina are just as human as we are, and catalogs are just as essential there as in the U. S. A. Many of our makers have not thought so and I have seen in Argentina and Brazil huge boxes filled with catalogs in English that were never used. The automobile salesman in Sao Paulo, Brazil or in Montevideo in Uruguay or at Buenos Aires had too good business sense to even think of distributing a catalog in English to prospects who do not know any more about English than we know about Chinese.

Get the business attitude of the Buenos Aires automobile dealer by a homely parallel: Conceive if possible that you are going to sell in the U. S. A. a new type of Chinese piano that some Chinese salesman has shown to you and explained to you by the few words of English he knows. Then this Chinese salesman leaves you a box of Chinese catalogs on this piano. You cannot read a word of the catalog yourself, but yet you are going to take them and mail them out to your prospects in New York or Chicago. Not one of these prospects ever spoke a word of Chinese but still you are going to mail them around. What asinine stupidity that would be.

But go a step further: That Chinese piano manufacturer has not an English stenographer in his office in Pekin and all the business letters you get are in Chinese. You do not understand them and you have to rely on the veracity of some translator. Then go a little further and keep in mind that you must pay for those Chinese pianos the day they leave the factory in Pekin or perhaps the day they are loaded on a boat to leave China. You may have your doubts as to whether they will ever reach you or not but that makes no difference. This parallel may savor of being extreme but it is hardly so when the business fundamentals underlying it are considered.

THIRD:—You must be prepared to go into the South American field with instruction books for your cars in Spanish and others in Portuguese. One automobile dealer in Sao Paulo, Brazil, told of having sold over 200 of a certain make of popular U. S. A. cars in the last 2 years and yet he had never received an instruction book in Portuguese. Think of

This illustration showing one of the narrow streets in the business section of Buenos Aires mut be compared with the illustration on the opposite page, showing the wide streets. These old-fashioned, narrow streets hamper traffic very seriously and with one row of vehicles along the curb there scarcely remains enough width for two motor cars to pass. There is not sufficient room for a wide motor truck to pass an automobile. On many of these narrow streets is a single street car line placed close to the curb on one side. There is only room for one vehicle at the side of a street car. It is nearly 15 years ago since the widening of these narrow streets was undertaken and already great progress has been made. By requiring all traffic on these narrow streets to travel in one direction it is possible to avoid traffic congestion and also have good speed; in fact you can make as good speed in a motor car on many of these one-way traffic streets as you can on the broader streets with traffic in both directions

it! There he was having sold over 200 cars to people who cannot speak a word of English and only understand Portuguese and yet they were expected to read in English all about this new automobile. It would be difficult enough for them to read the book in Portuguese for many of them are not very mechanical and require to be fed mechanics in homeopathic doses, but to add to the impossibility the heavy doses are given in English. Such a U. S. A. firm is succeeding in South America in spite of its own inexcusable bad business. Such a concern deserves no credit for what success it has already achieved and if such a concern expects to build up a substantial South American business it will only do so because of the great demand for our cars.

European Methods Approved

Everywhere in South America you hear of the good business policies of the European houses, particularly the Germans, who have the best reputation in South America for knowing how to develop trade. One dealer in Montevideo told me of how a large German house got into the Uruguay market. It built a medium-powered car and before the first cars arrived there reached Montevideo a case full of catalogs in Spanish and also a case filled with instruction books, posters, and general literature, all in Spanish. This literature was all corrected according to local customs in Uruguay so that every word used was the correct word.

But the German house had gone further and made the catalogs and instruction books much more elementary than those used in Germany or other countries. It had recognized the fact that the South American countries are not manufacturing countries, that their peoples are not so technical as are we in the United States, Canada and Europe, and that naturally a catalog or instruction book for South America must be much better illustrated than one used at home. Best of all this literature arrived before a single car was received, not months or years after 100 cars had been sold. Any U. S. A. maker going into the South American field can afford to take several pages out of the note books of German houses in building up South American business.

FOURTH:—You must be ready to give these South American countries the cars they want when they want them:

Selling.—In Argentina the selling season begins about November 15 and continues through December, January, February and to March 15. These are the big selling months. These are their summer months. Argentina being south of the Equator has seasons directly opposite to ours. When we are in summer they are in winter. They sit around and roast on Christmas day while we complain that the weather is too cold to go motoring.

Keep this selling season in mind and aim at having your your cars reach their destination in South America by November 1 or 15. The dealer must have them then.

In June I spent an entire forenoon with one of the largest dealers in Buenos Aires listening to him tell me about the impossibilities of doing business with one of our largest automobile makers. He had received only a few weeks before a big shipment of automobiles that were due to reach him last December. They arrived months after the selling season was over and now he has to keep those cars on hand until the next selling season opens in December. But then he will have 1916 models instead of 1917 ones. Fortunately the dealer in question is a very wealthy house and can afford to carry nearly 400 cars for several months, but the house will not be caught that way again and the U. S. A. factory has lost much prestige, because there are several dealers in many towns and cities of Argentina who have lost confidence in the company. Confidence is not an easy quality to restore.

There were twenty or more similar examples of this. The Buenos Aires representative of one of our oldest houses showed me the first 1916 model of his line which he got out of customs on June 15. He was promised it last October. Delay followed delay until the freight situation got tangled up and then the factory found it had to wait nearly 3 months to get steamer space. I visited several automobile dealers who did not get cars until the selling season was over and were carrying the 1916 cars over to the 1917 season.

You must work months ahead when developing South American business. It is not like at home where your dealer keeps after you and then you finally ship by express. It is practically 2 months from your factory to your dealer in Buenos Aires. Your first 1917 shipments should be leaving

This is a gasoline storage depot at Rosario, Argentine. The gasoline is carried in 5-gal. cans, two of these cans being crated. The gasoline is brought this way from U. S. A. and stored in long rows of these warehouses instead of huge storage tanks as in U. S. A. Argentine aims at having a supply of 5,000,000 gal. of gasoline and 5,000,000 gal. of kerosene in storage all the time.

This shows the first curbside gasoline depot in Buenos Aires. The equipment is a Bowser which was installed in May, 1916. The car being filled is a Jeffery four and standing to the right of the Bowser pump is George W. Gaidzik, South American representative of the Jeffery company. This curbside pump is proving a success, and it is probable that soon there will be hundreds of them in use.

your factory Sept. 1 providing you have shipping space arranged for and if shipping space is not provided you should be already on the job.

FIFTH:—Be prepared to give them the kind of cars they want at the time they want them.

Tread.—For Argentina they want cars with 60 or 62-in. treads for the camp or country. That is the tread of the huge farm carts that dominate the roads and it is just as essential to have the wide treads for the Argentine camp to-day as it was to have them in many of our Southern States 5 years ago. True we agreed to stop making wide tread cars because our U. S. A. roads are getting improved to that stage where we can get on with standard treads, but Argentina is not in that condition to-day, and if you are going into permanent business there you will have to build the wide tread.

Narrow Tread

It is true you can sell in Buenos Aires narrow tread cars but you cannot sell them in the camp. Better to keep out of Argentina business than to try to break in with the narrow tread. Ford and several others have found it good business to build the wide tread for Argentina and many other sections of South America and you will find it the same. In June some of our largest concerns agreed to build the wide tread for Argentina.

Steering.—Argentina rules of the road are opposite to those in the U. S. A. In Argentina you keep to the left, whereas we keep to the right. Argentines want the steering post on the right. They insist on that. Our best makers are giving them cars this way. Some of our makers are charging $8 extra for this and the Argentine dealers object to this. It is good business for him to pay the extra amount and get a car that will sell easily. A few of our companies shipped cars with steering wheels on the left and are in bad. In open country it does not make much difference whether the steering wheel is on the left or on the right but for city use it does, and where you have narrow city streets like many in Buenos Aires and in nearly all South American cities it is necessary to have the steering wheel on the right.

Left Steering for Brazil and Chile

In Brazil the opposite rules of the road apply, that is the same rules as are in vogue in the U. S. A. and so the steering wheel on the left is correct. The same is true in Chile.

Clearance.—Next comes clearance: Cars for the camp or country must have good clearance. They want 10 in. or preferably, more. They cannot get along well with much less. The camp roads have deep ruts, deeper than we are accustomed to here, and with low clearance you cannot get along at all. We saw one salesroom in Rosario stocked with a leading make of U. S. A. car of low clearance, and the owner was practically desperate. He had ordered higher clearance but the U. S. A. factory had not heeded the requirements. He had on his hands cars that he could not sell. He had lost several precious business months, and was not able to get larger wheels and tires. He was not going to place any further orders and was ready to give up the agency if he could only get out from under his present load. The dealer produced his order duplicates to prove that he had specified clearance and it was apparent that the factory had not given heed to this requirement. As a result the dealer had lost confidence in the U. S. A. factory and you could not blame him. That is one way in which you cannot build up a South American trade. If you cannot give the right clearance, then do not ship cars until you can.

Colors.—Give the dealer in Argentina or Brazil or Chile the color he wants and the color of car you agreed to supply him with. This is very rarely done. One of our largest automobile factories lost its agent in one of the biggest South American cities on July 1 simply because it shipped cars with colors different from those ordered. This dealer placed orders, let us say for one touring car in green, one in blue and three in red with black striping. The dealer had sold the cars with these colors and was duty bound to his prospects to give them such. When the cars arrived they were all painted black and not a single prospect would take them. The dealer had difficulty getting them painted the correct color. It cost him over $100 each and the company would not make any allowance to him. Naturally he was through with that factory and naturally that factory is receiving a black eye in that market. The dealer has already given up the agency. His opinion of the U. S. A. factories has not improved because of his experince.

You must be prepared to give the South American dealer the car he wants, the color he orders and at the time he wants it, as well as the type of body he orders.

Sent Closed Cars Instead

Bodies.—In Sao Paulo another glaring example of poor U. S. A. business methods came to my notice: One of the large implement dealers in this city of 500,000, located in the finest section of Brazil and in a section that compares with any area in all South America wanted the agency of a certain Detroit car. Through his New York exporting house

he asked for three or four touring cars to be shipped in order that he might test them to decide if he would take an agency for the State of Sao Paulo. When the cars arrived there was only one touring car, one other was a coupé, and two were sedans. This implement agent had been selling U. S. A. cars for nearly 4 years and had been selling only in the camp. There was no demand in the city. Picture his chagrin on receiving out of the four cars, three that were entirely unfitted for the country, and three cars that had been on his selling floor for months and which he had no chance of selling. In the country they want five- or seven-passenger touring cars. They are not interested in closed types.

You say why not sell the closed types in the city. There were many reasons making that practically impossible: First, in all South American cities they use chauffeurs and they will not have a chauffeur sitting in the same compartment with them. Caste is different in South America than in the U. S. A. and while in New York or Chicago a family will have the driver in a sedan or coupé they will rebel at such in South America. A woman in Buenos Aires or Rio could not be induced to drive in a sedan with the chauffeur.

Shipped Wrong Body

In Buenos Aires another similar example of the U. S. A. foolishness was seen. In the top floor of a large salesroom was shown a beautiful three-passenger coupé that had been shipped in place of a town car. The dealer could not get any one interested in it, and after having it in storage for nearly 3 years was having the body removed so as to fit a delivery wagon body to it. The body had been a total loss and the company he was dealing with was willing to wipe off the body cost as a penalty for its error.

Again: We could site examples by the score of similar inexcusable acts on the part of our automobile makers and exporters, but only one more will be cited, in the hope that it will analyze the situation sufficiently fully: A Sao Paulo dealer ordered a touring car of a particular shade of blue. It arrived in due time but the body finish was ruined because the packing paper was sticking into the varnish. Apparently the body had not been sufficiently dried. It was crated too green. The dealer had paid $60 extra for the special color and had waited several weeks for it, only to have it arrive in a spoiled condition. He had it repainted in Sao Paulo at a cost of $110 and as the Detroit company had not agreed to rebate the $60 for its error when I was in Sao Paulo, the dealer was not in a loving attitude at having to pay $170 for a special color. Keep in mind that Brazil, Argentine and all southern South American dealers are nearly 2 months from your factory, by the freight route, and their orders should receive the very carefulest consideration. It is different if you make an error on a Chicago or New York order, where the dealer can care for the job with little loss of time, but not so in South America.

Give 3 Months' Credit

SIXTH:—Be prepared to give 3 months' credit on goods sold to South American dealers. This applies to practically all dealers. There is scarcely any reason now why you should not do this. With the National City Bank of New York with branches in Rio de Janeiro, Santos and Sao Paulo, Brazil; with its branch in Montevideo, Uruguay; and with its branch in Buenos Aires, and agents in other parts of Argentina; and with prospects of it opening branches in other countries, there is no just reason why you cannot get all of the credit information on any prospective dealer you may want to sign a contract with. This bank has had in operation for a long time a very competent credit department in all of its branches and is ready to give any and all information that our makers require. So far as credits go you are now on a par with European houses.

Feature of Novel Steel Wheel Is Simplicity

ALMOST the simplest of all steel wheels is a recently patented device of British origin, of which a sample has just been imported. It has the advantages of lightness and extreme cheapness, while it can accommodate any form of demountable rim. It may be described briefly as a disk wheel in which the disks are largely cut away, and the illustrations make clear the construction.

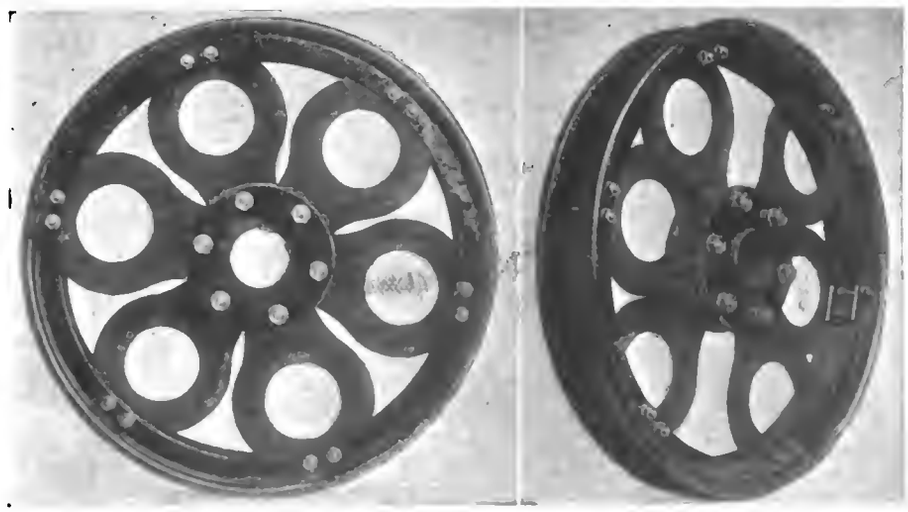
Stamped Side Plates

The side plates are stamped from sheet steel and bolted to the hub and to little brackets riveted within the felloe, and the removal of a dozen nuts reduces the wheel to its elements. Except upon the hub, there is practically no machining, as the bolt holes in the felloe and in the side plates are punched in the press. Neither hub nor felloe band is any more complicated than for a wood wheel, and it is stated that the side plates can be stamped, and the wheel assembled, for less money than a wood wheel can be built.

In appearance the wheel is distinctive, and it has a look of lightness in contrast to the massiveness which is characteristic of the full disk wheel. Its lateral strength is not comparable with that of a wire wheel, of course, but it should be at least as great as that of a good wood wheel. The inventor also points out that if the wheel should be buckled by some exceptional skid, it is only necessary to take it apart in order to hammer the side plates flat again.

To Market the Wheel

The wheel is called the Blakoe Double Trefoil, and the American rights are at present in the hands of G. W. Morrison, 1170 Broadway, New York City, who hopes to be able to conclude arrangements with interests in this country which will enable him to put the wheel into regular manufacture on a commercial scale at an early date.



Blakoe double trefoil wheel, which is built up of two steel stampings, and is very light and simple

Willys-Knight Now Carries Seven

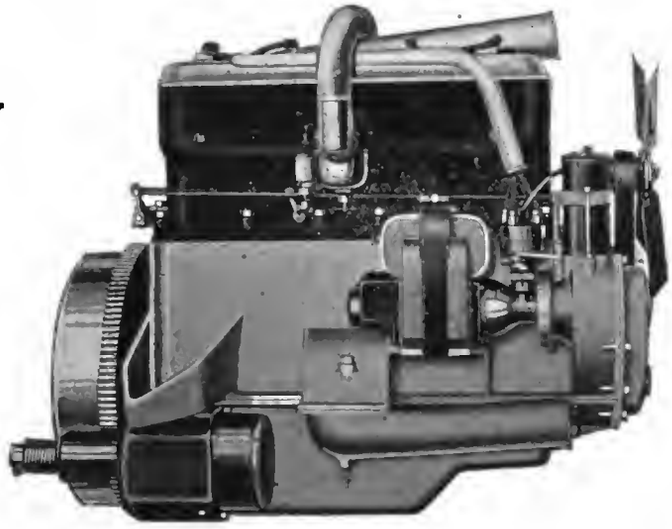
Body Lines Better — Improved Cantilever Springs — New Axle and Gearset Unit—Prices Higher

THAT the new Willys-Knight four is the handsomest and most comfortable car ever turned out of the Willys-Overland factory in Toledo, Ohio, is beyond all question. It is a seven-passenger car with all the most modern lines and fittings; it has an improved system of cantilever spring suspension; it has a completely new rear axle and a new gearset in combination with the axle. Naturally, with all these improvements the price has been increased to $1,285 for the touring car, in addition to which there are two closed types at $1,950. Of these, one is a seven-passenger touring sedan of the Springfield pattern, with a permanent top and glass windows which remove completely, and the other is a seven-passenger limousine.

On all three models great care is taken with the finish, which is to be maintained at a quality in keeping with the fine lines of the bodies. It is becoming almost platitudinous to describe a 1917 car as having a custom-built aspect, but this is really the best way to sum up the external points of the new Willys-Knight.

Battery Ignition Used

As to the chassis, the wheelbase is now 121 in., but the changes in detail, considerable though they are, do not appear at a glance. The engine, 4⅛ by 4½ in., is the same as the 1916 series, except for the ignition which is the Connecticut battery system instead of the magneto. The electrical equipment is all Auto-Lite except the actual distributer; the generator, which is very little larger than the magneto, is mounted on the engine right and chain-driven direct from the crankshaft. With it the ignition unit is combined and the coil is mounted in a clip on top of the chain case, this making the wiring of minimum length. To drive the generator the chain pinion has an internally toothed ring outside the case, and the generator shaft a pinion with a corresponding number of teeth which fits inside the ring. This gives the small amount of universal action required to allow for minute differences in alignment and also allows the generator and igniter to be removed by merely detaching the wires and undoing a single screw holding the clip which retains the generator on its platform.

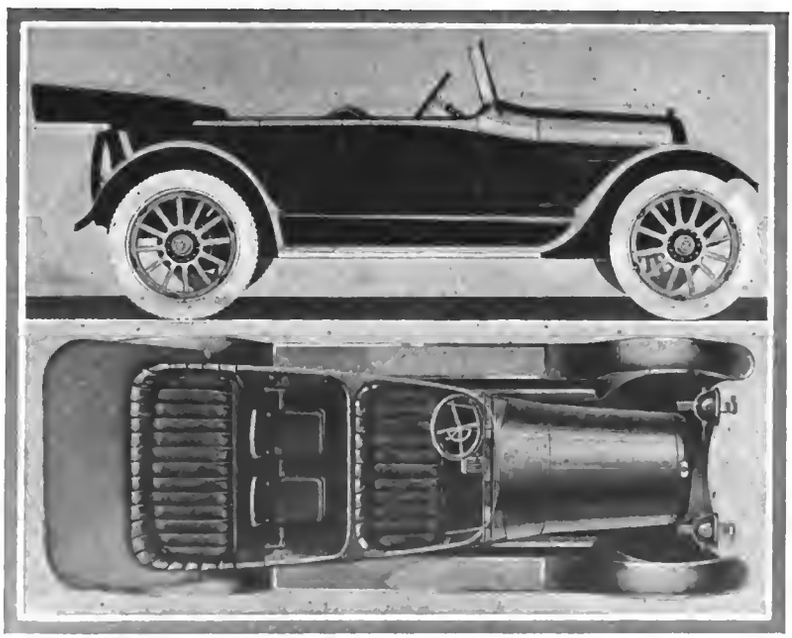


Intake side of four-cylinder 4⅛ by 4½ in. engine used in the Willys-Knight, showing high mounting of carbureter and also the position of the electrical units

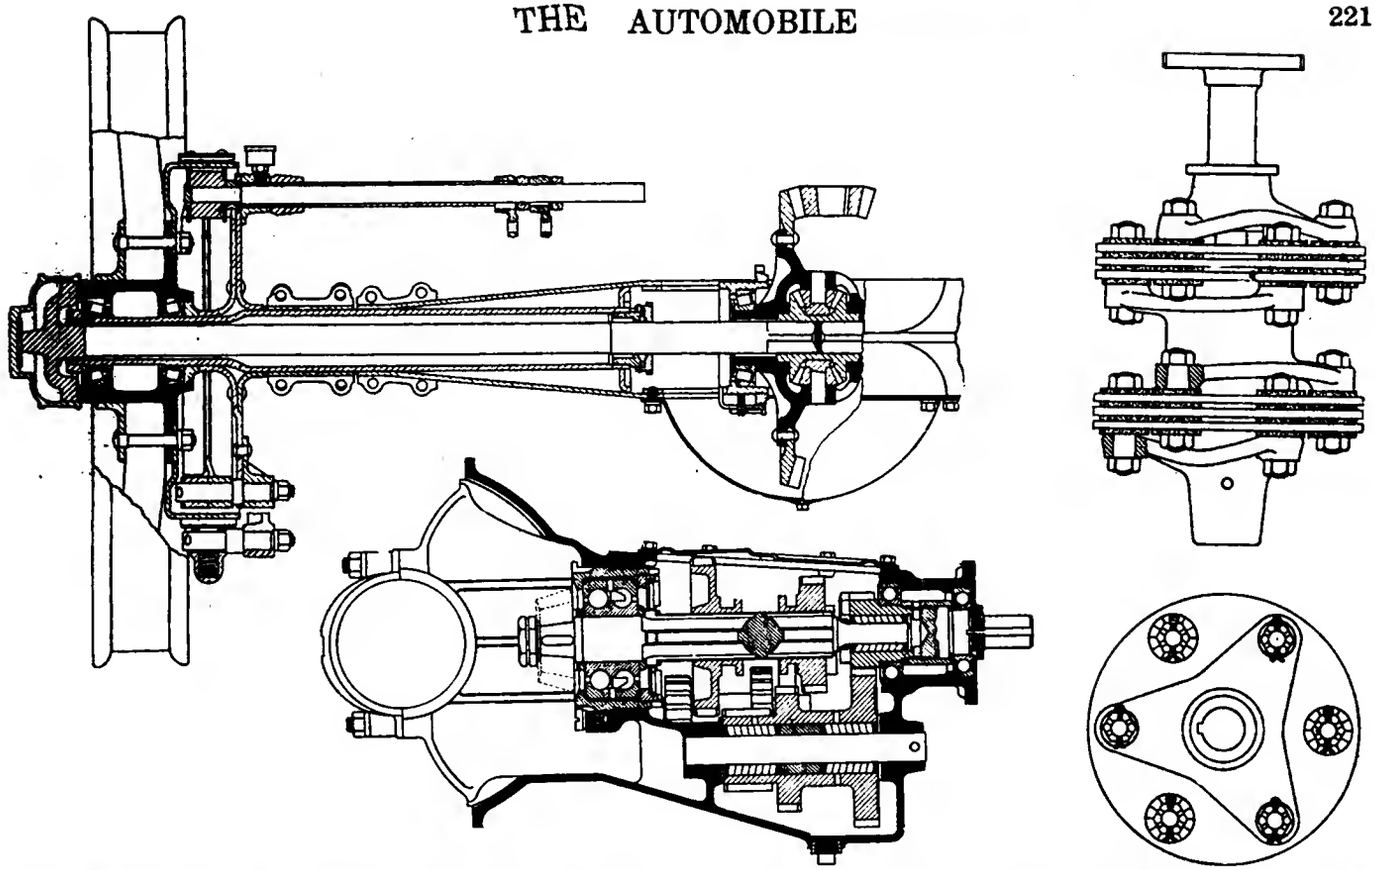
The starting motor has a Bendix pinion which draws forward, toward the body of the motor, to engage, so that there is a minimum of overhang when the starter is operating. The motor lies just beneath the right rear supporting arm of the engine where it does not interfere with the accessibility of any other part. Completing the electrical system, the battery is housed beneath the floor in the driver's compartment, on the right, and is accessible through a detachable panel in the guard strip which joins the running board to the frame.

One of the features of the engine is the system of lubrication. The earlier Knight engines were all splash lubricated, but the Willys-Knight has a pressure feed to each main bearing on the crankshaft, whence drilled holes carry the oil to the connecting-rod ends. Thence the overflow is whirled out by the cranks, so reaching the sleeves which are grooved to conduct an adequate supply to every part of the working surfaces. The oil pump, a plunger pattern, is located in the base of the crankcase, and the supply delivered to the bearings is controlled by a throttle working in conjunction with the carbureter throttle, so that the engine receives oil in proportion to the work demanded at the moment. One noticeable result of this control is that the engine is not prone to smoke.

Experience with the 12,000 cars made in the past year shows that this engine has the quality common to all Knight motors of insusceptibility to carbon. First, carbon does not form so fast as in an L-head engine and, second, when it does form it has much less effect on the running. Up to a point carbon is actually beneficial to a Knight engine, putting a sheen on the sleeves and port edges. The exact reason why this should be so has not yet been stated, but probably the absence of trouble due to presence of



Willys-Knight seven-passenger touring car which sells for $1,285. Note the attractive body lines and comfortable seats



Above are illustrated the new axle and gearset unit of the Willys-Knight showing the banjo-shaped steel stamping now used, the differential being carried on brackets projecting from the back of the gear-box. At the right is illustrated the new universal joint which consists of two sets of leather disks, each set comprising three disks

carbon is because of the almost spherical shape of the combustion space, and the absence of any roughness. In a Knight engine every part of the combustion chamber is machined, and there are no angles or pockets to house the deposits which could get red hot and cause pre-ignition.

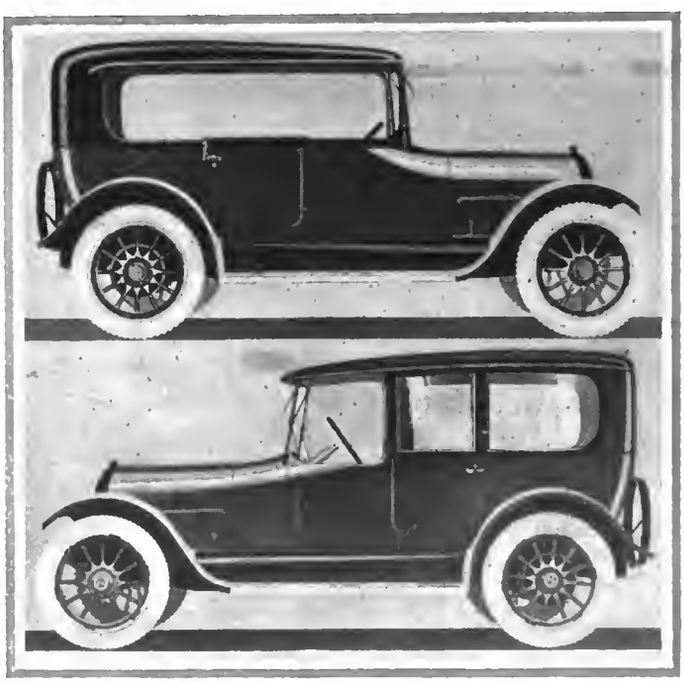
Thermo-Syphon Cooling Continued

Thermo-syphon cooling, used for the 1916 series, is retained. There is a passage through the crankcase which makes the inlet to the cylinders from the radiator, as seen in the illustration of the right side of the engine. From the top of the cylinders a large aluminum header returns the hot water to the radiator, the water path being almost ideal for straightness and freedom from twists.

Carburetion is by a horizontal Tillotson instrument bolting to the cylinders and drawing hot air from a muff on the exhaust pipe. The gasoline tank is at the rear with fuel supply by Stewart vacuum feed.

The transmission system follows the same general lines, that is, the gearset is in a unit with the rear axle and a stout torque tube incloses the propeller shaft. This torque tube is hung on pivots at the front, thus taking both the driving torque reactive stresses. Though, at first glance, the gearset appears much the same as previously, it is actually a complete new design, having the countershaft beneath the mainshaft instead of beside it. This change makes the box narrower and so stiffer. Three speeds are used and the arrangement of the bearings is rather out of the ordinary. The tail end bearing on the mainshaft takes the bevel pinion thrust, so a large double-row, New Departure ball bearing is used. At the front end of the mainshaft is a substantial single-row ball race. The spigot bearing is a Hyatt roller. The countershaft is fixed in the case, the whole set of countershaft gears being assembled into a unit which is bored out larger than the fixed shaft, the space between being filled completely with Hyatt rollers from end to end.

Another notable change is in the rear axle construction. Formerly the axle had a cast center case with tubes bolted to it, but now there is a steel stamping of the so-called "banjo" form, the differential being carried on brackets projecting from the back of the gearbox. At the back of the axle a simple cover plate completes the inclosure of the differential so that inspection is possible with the removal of only a few nuts. The road wheels are mounted outside tubular sleeves which are fixed in the ends of the banjo stamping, so the



Above is the Willys-Knight touring sedan, with permanent top and removable glass windows, and below is the limousine. Both models sell for $1,950

new axle is full-floating. Throughout it Timken bearings are used.

For the brakes there is the conventional layout of external and internal on the same drums, but attention should be given to the very substantial shoes used for the internal portion, giving a rigidity to the working surfaces which results in a very smooth, though powerful, action.

Leather Universal Joint

Still another transmission change is in the universal joint which is now made up of six leather disks in two sets of three disks. This gives perfect universality without any metallic moving parts, there are no surfaces to wear and nothing that can ever make a noise. The life of the leather is said to be entirely satisfactory and it is worth noting that real leather is used, not a composition. Actually it is much the same sort of leather as is commonly employed for facing cone clutches. The flexibility of this universal is quite remarkable; it feels, when moved by hand, as free as any metal joint and more free than some of them.

The cantilever rear springs are 48 in. long and 2½ in. wide, and applying the test of driving across a railroad at 20 m.p.h. proved their ability to absorb shock. At this speed the rear seat passengers can just feel the crossing, but are not shaken off the seat, and the front seat occupants feel nothing. In handling the most noticeable feature is the ease of gear shifting, due to the soft acting cone clutch and the strong clutch brake which quickly brings the cone to rest. Still, with a high gear ratio of 4.6 to 1 which is the standard, there is little need for the shift lever, as the engine operates smoothly down to 5 m.p.h. and even below this speed. Another point which is noticed when driving the car for the first time is that there is no apparent increase in vibration at high speed. At 20 m.p.h. there is a slight tremor which can be felt in the front seat but not in the rear one. At 40 m.p.h. this tremor is, if anything, less noticeable, while the engine is, of course, just as quiet at 50 as at 20. The pulling at slow speed is markedly good, and the acceleration smooth and easy.

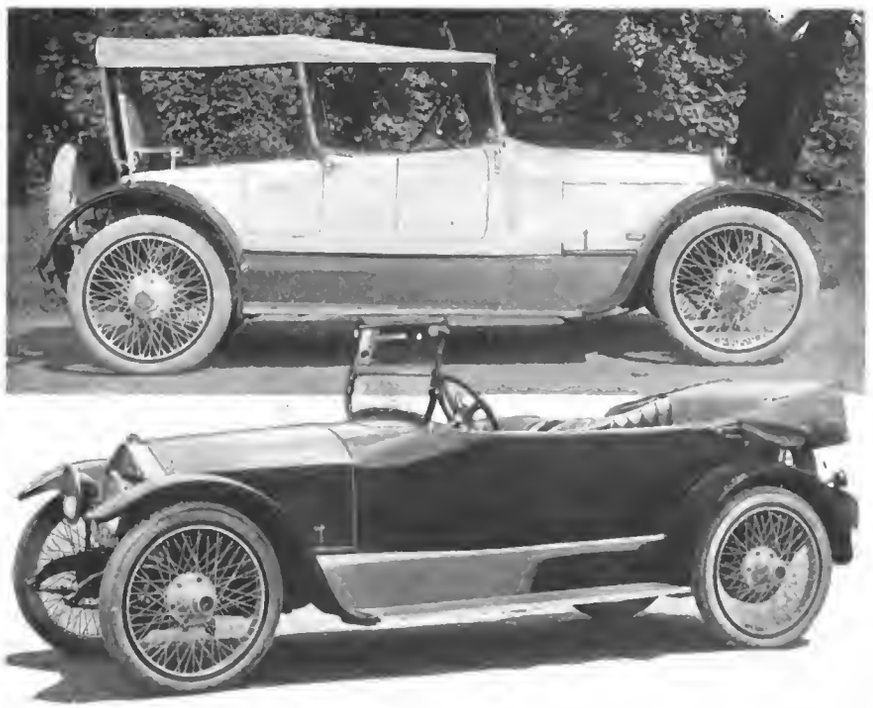
Bodies Strong and Well Furnished

Coming back again to the bodywork, this is much more rugged in construction and great pains have been taken to strengthen all points where weakness might lead to squeak or rattle production. The engine being so quiet the need for soundless bodywork is greater than ever, and this can only be obtained by solidity of frame and careful fitting of doors, etc. The upholstery is deep and very soft, both the cushions and the back padding being the kind that the body sinks into. Whichever way one leans there is a springy "give" conforming to the attitude taken. For the cowlboard and for the back of the front seat into which the folding seats disappear a grained finish is employed, so cunningly devised that the closest examination does not disclose the fact that the material is really steel. The carpet used in the tonneau is of heavy material in keeping with the leather of the upholstery.

Radiator Shell Changed Slightly

A small change which has not been mentioned is in the radiator shell. While still distinctively Willys, this now has a bulge at the front of the top tank, slightly overhanging the core and rounding out the lines of the front end. All the usual accessories are neatly arranged in the cowlboard, the magnetic speedometer, electrical gages and oil pressure gage, while a little glove cupboard occupies a part of the board not needed for anything else. Included in the equipment are a Boyce Moto-Meter and a gasoline gage. All the finish is dark rich blue, upholstery, body and hood all matching. The road wheels are gray and black is used for the fenders; fittings are of nickel or polished aluminum. For tires, the size is 34 by 4½ in., the touring car having plain treads on the front wheels with non-skid on the rear, while the closed cars have non-skid all around. There is a spare demountable rim included in the equipment.

Custom-Built Bodies on Roamer Chassis



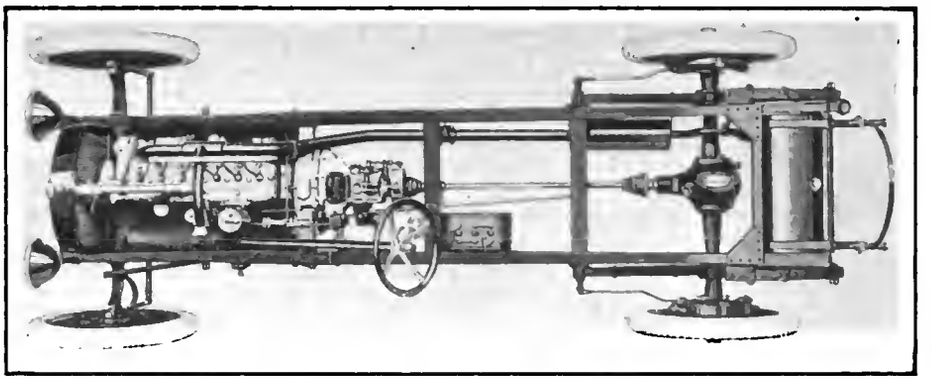
These illustrations serve to give an idea of the custom-built bodies which are applied to the Roamer chassis. A feature of these cars is their low-hung appearance

ROAMER cars are being produced in a number of designs of pleasing variety in carrying out the company's policy of using custom-made bodies. The illustration herewith shows two types of body, the upper being a special four-passenger roadster job, selling at $1,900 and the lower the regular club touring model listed at $1,800. Mechanically, these cars are all mounted on a stock chassis of 124-in. wheelbase. They have the 3⅛ by 5 Rutenber engine fitted with Bosch magneto ignition and Bijur lighting and starting. Other special parts and fittings are the Hess axle, Grant-Lees gearset and Houk wire wheels. The cars are offered in a great variety of finish, and as a matter of fact, each purchaser has his choice of color.

Harry J. Everall, Inc., who is now handling the car in New York City, has placed an order for 150 of the Roamer chassis and for twenty-five special closed bodies for the New York trade. In Boston, arrangements have been made with Alfred Morse, agent for the Rolls Royce and Lancia companies, to handle the Roamer and in Philadelphia, the Oliver agency, handling the Mercer cars, will take on the Roamer.

New Jeffery Six Is 3 In. Lower

Rear Axle Re-Designed and Springs Underslung—Crankshaft Balance Better—Unit Power Plant 3½ By 4⅝—Body Comfort a Feature



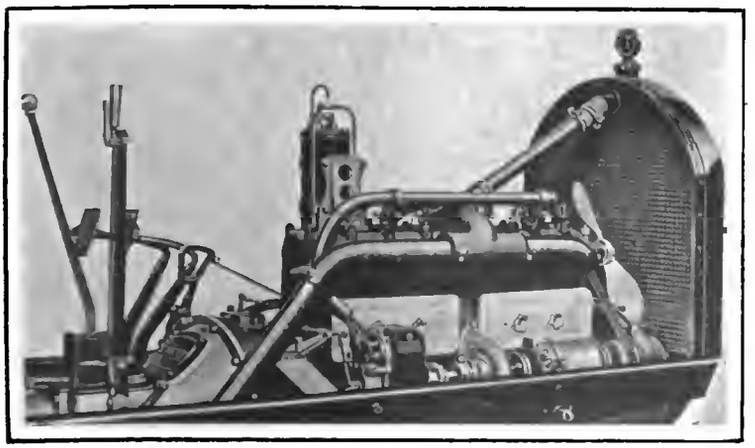
Jeffery six chassis, showing mounting of unit power plant, battery and fuel tank. Note clean design

IN addition to the Roll Edge four which was announced 2 months ago, the Thomas B. Jeffery Co. of Kenosha, Wis., has brought out a six-cylinder model for 1917 under the series number of 761.

Probably the outstanding feature of the new Jeffery six which will retail at $1,365, or $85 lower than the previous six, is its low body and general comfort in seating arrangement. This low effect has been accomplished by redesigning the rear axle so that the springs are now underslung. In this car the line of vision is 7½ in. lower than it was in the previous six. In addition to this improvement a more perfectly balanced crankshaft is used, resulting in a smoother acting engine so that the two details of body comfort and more quiet engine action have combined to give a much better performing car.

Floor Is 3 In. Lower

Summing up the body improvements, the floor of the new six is 3 in. lower than that of the 1916 model. The running board is now 15 in. from the ground and to add to the low, long appearance, the windshield has been given a pitch of 16 deg. and is now 20 in. high. Nowhere on the body is there a flat surface, every piece of metal being of double curvature. The upholstery is better and the dimensions of the seats are more liberal. For instance, the rear tonneau seat is 48 in. wide and 18 in. deep and the distance from the front of the back to the back of the front seat is 32 in. The auxiliary seats have also been made more comfortable and passengers occupying these are allowed 9 in. of knee-room. The seats themselves are 14 in. deep and there is 8½ in. knee-room between the passengers in the rear seat and the auxiliary seats.



Exhaust side of the new Jeffery six engine, showing its low mounting. Note hot air connection for carbureter, drive of electric units and two-bladed aeroplane type fan

3½ by 4⅝ Unit Power Plant

The unit power plant has its six 3½ by 4⅝-in. L-head cylinders cast in a single block with the upper half of the crankcase integral. This is an iron casting and to it is connected the pressed steel pan which forms the lower half of the crankcase. The valves are carried on the right side.

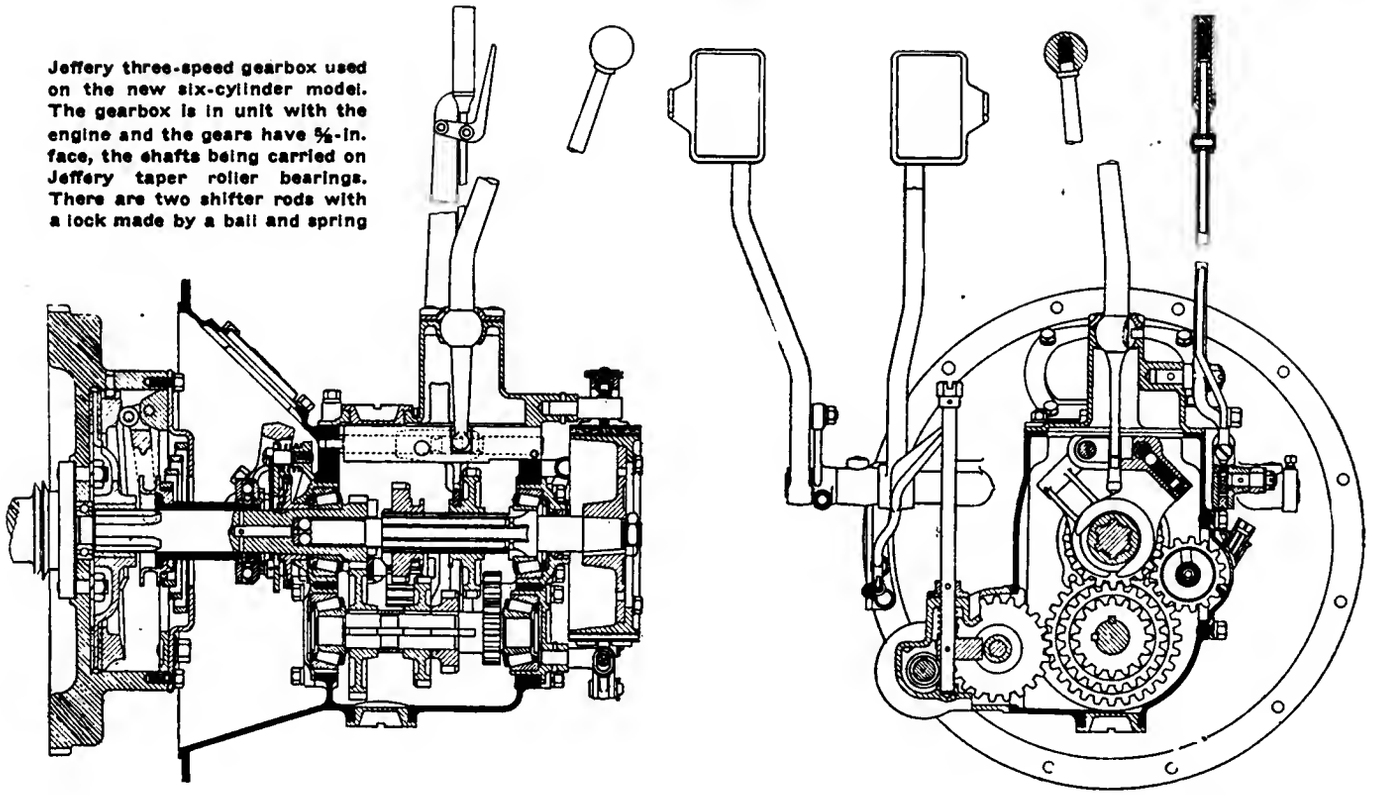
In line with present practice the reciprocating weights of the Jeffery engine have been kept very low. The entire weight of the piston with rings and pins is 1 lb., 7¼ oz. The pistons are of aluminum alloy and weigh but 1 lb. The length of the piston is 3⅞ in. and these are fitted with piston pins having a diameter of 1 5/16 in. The rings are three in number and are of the eccentric type and made from gray iron.

Drop forge alloy steel connecting-rods are used, having a length of 9½ in. The weights of these rods are 3 lb. 2¾ oz. and at the lower ends the caps are fastened by two chrome nickel steel bolts, at the upper end the piston pin bearing is carried in a phosphor bronze bushing, located in the connecting-rod. The lower end bearings are of die cast babbitt and have a length of 2 in. The diameter of the crankshaft, which is a forging of 0.35 to 0.45 carbon is 2¼ in. and this is laid out to be inherently balanced. It is carried on three main bearings, the dimensions being as follows: Front, 2¼ by 2 3/16 in.; center, 2¼ by 2½ and rear 2¼ by 3¼.

A one-piece drop forging makes up the camshaft from which the entire valve drive is taken. Mushroom type followers are used and the camshaft is carried on four bearings. All of these are of liberal size, the shaft diameter being 1 5/16 in. The length of the front three camshaft bearings is 2 1/16 in. and the rear 1 in. The diameters are 1⅛ in. for the center pair, 2 11/16 for the front and 2¼ for the rear.

Conventional valve timing is used with the inlet opening at 8 deg. after top center and closing 40 deg. after bottom center. The exhaust opens 40 deg. before bottom center and closes 8 deg. after top center. In other words, there is a zero lap, since the intake opening and exhaust closure are coincident. Morse silent chain is used to drive the camshaft, the chain being 1¼ in. in width and operating on drop forged sprockets with adjustable centers.

Lubrication is by combined pressure and splash with oil forced to all the main and camshaft bearings and



Jeffery three-speed gearbox used on the new six-cylinder model. The gearbox is in unit with the engine and the gears have 5/8-in. face, the shafts being carried on Jeffery taper roller bearings. There are two shifter rods with a lock made by a ball and spring

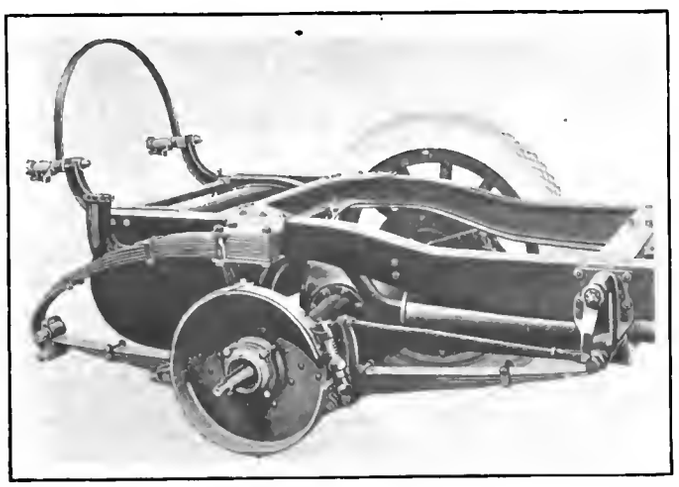
also to the driving chain. In addition, oil is fed to splash troughs into which the connecting-rods dip, taking care of the connecting-rod bearings, piston and piston pins.

Gasoline feed is from the Stewart vacuum system to a Rayfield Model M-3 carbureter. This is a 1¼ in. instrument fitted with a hot air tube. In the intake manifold special care has been taken to give a free passage to the gases and in fact this has been carried right through to the valves which have an overall diameter of 1¾ in. with an inside seat diameter of 1 9/16 in. and a lift of 5/16 in. These are the ordinary 45 deg. poppet valves and the material from which they are made is tungsten steel on the exhaust side and nickel steel on the inlet.

Two-Unit Starting and Lighting

Electrically, the car is Bijur for lighting and starting and Splitdorf for ignition. The Dixie magneto is used in combination with A. C. spark plugs located in the cylinder head midway between the valves and the cylinder bore. The starting and lighting system is in two units with a 20-lb. Bijur motor capable of turning over the engine at 160 r.p.m. and a generator mounted on the pump shaft. The battery is a U. S. L. 6-volt type of 80 amp.-hr. capacity weighing 48 lb. This is a lead plate battery. The lamp equipment is by Edmonds & Jones, operating at 6 volts with 18-candlepower headlamps. Throughout the entire lamp equipment the Ediswan base is used with single contact.

From the engine, the drive is taken through a Borg & Beck three-plate clutch to a Jeffery three-speed gearbox. There are one steel disk and two asbestos friction plates in the clutch, which is located in the flywheel. The gearbox is in a unit with the engine and is arranged to provide ratios in the box of 14.61; 8.2 and 4.5 to 1 of the rear wheels. The width of the gear face is ⅝ in. and the shafts are carried on Jeffery taper roller bearings. There are two shifter rods with a lock made by ball and spring. The drive shaft has six splines and the shaft center distance is 3½ in.



Rear construction of the new Jeffery six, showing mounting of underslung three-quarter elliptic springs for Hotchkiss drive, and also brake, fuel tank and spare tire carrier

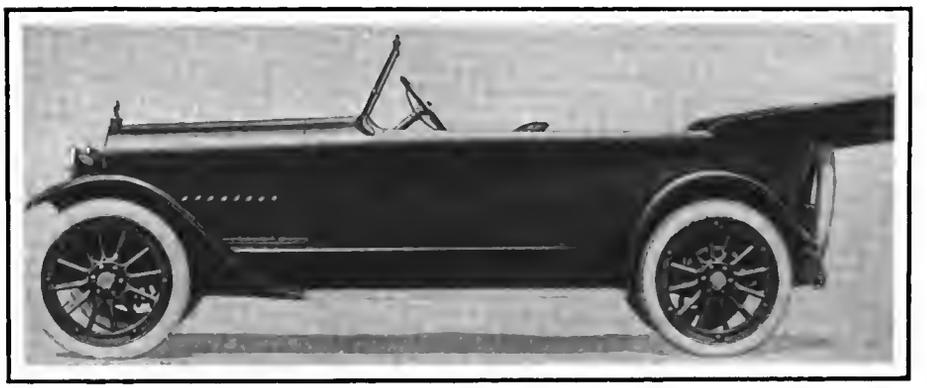
Jeffery Semi-Floating Axle

A Jeffery semi-floating rear axle is used in which the ratio is 4½ to 1 as regular equipment, although 4 2/14 to 1 and 4 10/11 to 1 can be furnished. This arrangement is secured by a fifty-four-tooth bevel gear with eleven, twelve, and thirteen-tooth pinions respectively. The gear teeth are spirally cut and have a 5 pitch. The differential is a bevel gear design and throughout taper roller bearings are used. In making up the axle housing a malleable iron center is used with alloy steel tubular ends. Both the drive and torque are taken through the springs by the Hotchkiss drive.

The spring equipment is manufactured by the Detroit Steel Products Co. The rear spring is three-quarter elliptic, underslung and is 53 in. long with eight leaves in the lower part and seven in the upper. The width of the spring is 2 in. the front springs are 38 in. long with eight leaves and 2 in. wide. The front axle is a Jeffery drop forged I-section with 9½ in. clearance, it is fitted with a Gemmer steering gear of worm and wheel type.

In the frame construction the side members are of the usual channel shape made with a single drop and the depth of the channel is 5 in. with 2 21/32 in. flanges. The frame

is provided with four cross bars with the side rails extended at the rear to provide a support for the gasoline tank and spare tire. The width of the front end of the frame over the front axle is 30 in. and over the rear axle it is 31¼ in.



New Jeffery six touring car which sells for $1,365, including full equipment. This car has a 125-in. wheelbase and uses 34 by 4-in. tires

Wire Wheels Extra

Artillery type wheels are used with twelve spokes front and rear. The spoke width is 1⅛ in. The wheels are made from hickory on the standard equipment, although Houk wire wheels will be fitted at additional cost. The rims are Stanweld of the straight side detachable type and designed to fit any straight side tire. The tire equipment on the standard cars is Goodyear with plain tread and front and the All-Weather non-skids in the rear. The tire size is 34 by 4 in.

On the six-cylinder car there are three bodies, the seven-passenger touring selling for $1,365, seven-passenger sedan at $1,530 and roadster at $1,335. Full equipment is included at these prices and all are mounted on the same wheelbase of 125 in. The equipment includes one-person top, Jiffy curtains, rain vision sloping windshield, rope straps, foot rest, extra rim, complete set of tools, Boyce Moto-Meter, Stewart power-driven tire pump and electrically lighted instrument board with speedometer, ammeter, oil gage, ignition switches and carbureter adjusting device.

—

An Electric Truck with Trolley Battery

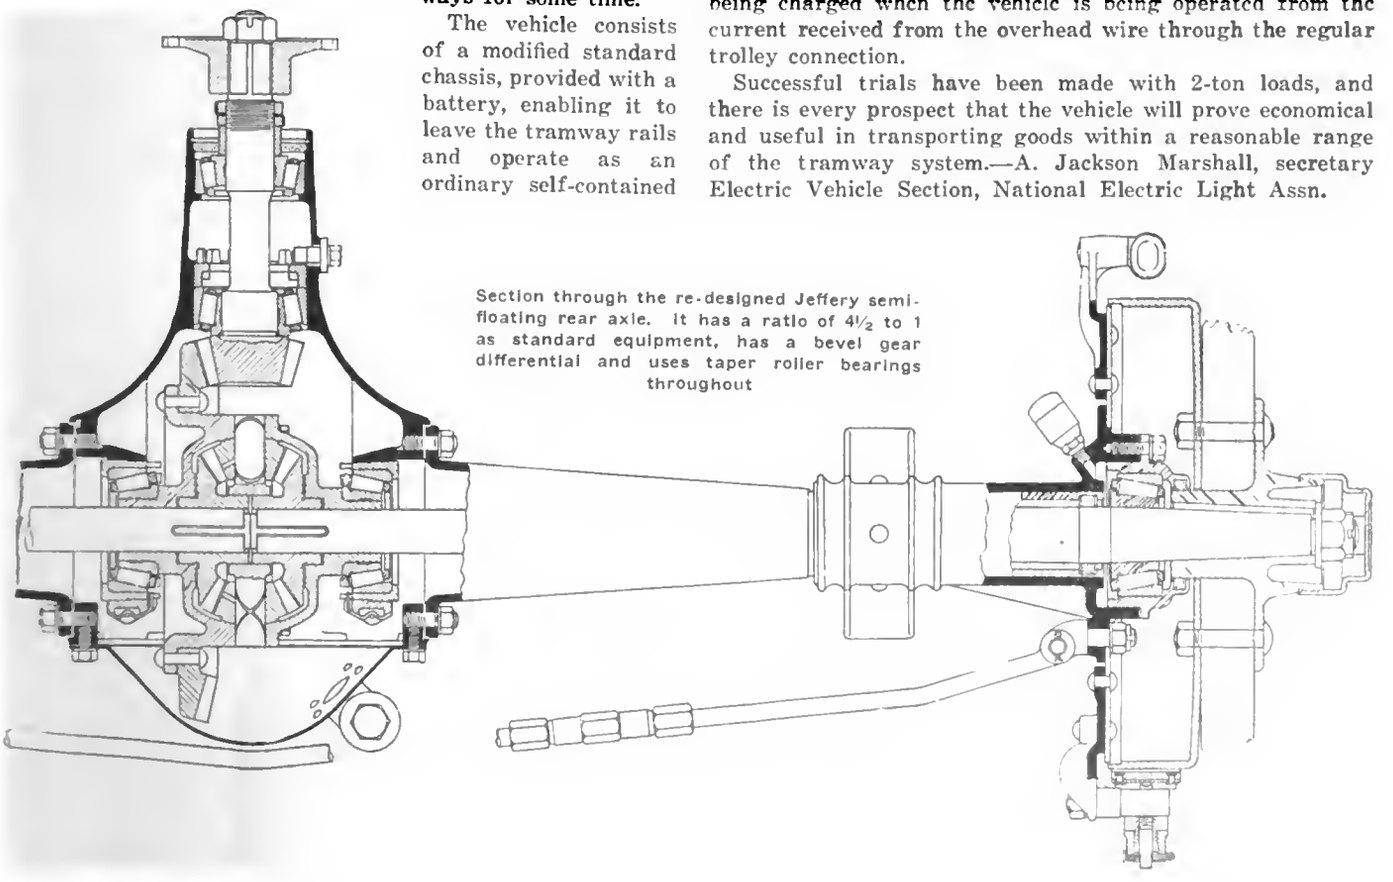
AN electric commercial vehicle which operates from an overhead trolley when traveling on tracks and on a trolley battery when on the road has been successfully used in Bradford, England, by the Bradford City Tramways for some time.

The vehicle consists of a modified standard chassis, provided with a battery, enabling it to leave the tramway rails and operate as an ordinary self-contained vehicle when the occasion demands, which is often the case in conveying material to a point beyond which the current is not available from the overhead trolley wire. The vehicle in question, in addition to being self-contained for special work, is also equipped with standard electric street-car equipment, including a trolley through which the current may be obtained, contact with the rails being made by means of a cast-iron block to the steering gear, and automatically steering the vehicle. The motors are of 20 hp., operating normally at 500 volts on the usual series-parallel system of control.

When the vehicle leaves the tramway route, the rail contractor is lifted, the trolley pole pulled down and a switch moved to bring the batteries into action. Owing to their lower voltage the speed of the free running provided by the batteries is slightly lower than the normal trolley speed, but the vehicle remains able to surmount any gradients.

The connections are arranged so that the batteries can be charged while running on the tramway routes. The normal range of the vehicle on one charge of the battery is about 10 miles, which, of course, may be extended by the batteries being charged when the vehicle is being operated from the current received from the overhead wire through the regular trolley connection.

Successful trials have been made with 2-ton loads, and there is every prospect that the vehicle will prove economical and useful in transporting goods within a reasonable range of the tramway system.—A. Jackson Marshall, secretary Electric Vehicle Section, National Electric Light Assn.



Section through the re-designed Jeffery semi-floating rear axle. It has a ratio of 4½ to 1 as standard equipment, has a bevel gear differential and uses taper roller bearings throughout

French Army School Trains Drivers

Some of the school cars returning from a practical road test for the drivers

Course Combines Theoretical and Practical Repair Shop and Road Work

By W. F. Bradley

Special Representative of THE AUTOMOBILE in France

PARIS, July 12—An army truck driver for convoy formations can be trained in 15 days. A capable touring car driver cannot be produced in less than 6 to 8 weeks. This is the experience of the French army authorities in the training of thousands of men who have not had previous automobile experience.

From their various regimental depots the men are sent in batches to a big automobile school which did not exist a few months ago. Everything has had to be created since the outbreak of war: officers and instructors, sheds for the men to live in, kitchens to cook their food, shops to repair the trucks, and a uniform program of instruction calculated to produce the best drivers in the shortest possible time.

The methods adopted for the training of a touring car driver are entirely different from those applied to the production of a truck driver. The latter is rarely, if ever, called upon to work entirely unaided. The touring car driver, on the other hand, must always be independent of outside help, and be sufficiently expert to get his car home no matter what conditions may be met with en route. Speed is a difficulty. While any ordinary man, without previous experience of motoring, can be trained to drive a truck, a certain proportion of recruits above 30 years of age are naturally incapable of becoming the drivers of mile-a-minute cars.

Theory and Practice Combined

The method adopted at the leading French army touring car school is a judicious combination of theory and practice. The pupils are divided into classes, of which there are about a dozen, each one in charge of an instructor. At the entrance to the avenue about thirty men are gathered round a sectioned automobile chassis. It is a Darracq of simple construction from which the radiator has been removed and the front of the timing gear housing taken away. A part of the waterjacket and cylinder walls has been cut out of No. 1 and No. 2 cylinders, to expose the two pistons. A color scheme has been adopted as an aid to comprehension. Thus the water pump, the inlet and outlet water pipes, and the exposed portion of the waterjacket space are painted a uniform color. The accelerator, the gasoline feed pipe and the carbureter are another color. The brake pedal, rods, shoes and drums have all been daubed from the common pot, and so on throughout the entire chassis, thus making it easy for the novice to trace the connections from one part of the machine to another. In this class elementary instruction is given to men who have for the most part entered the school without any notions of automobile construction and operation.

Learning to Shift Gears

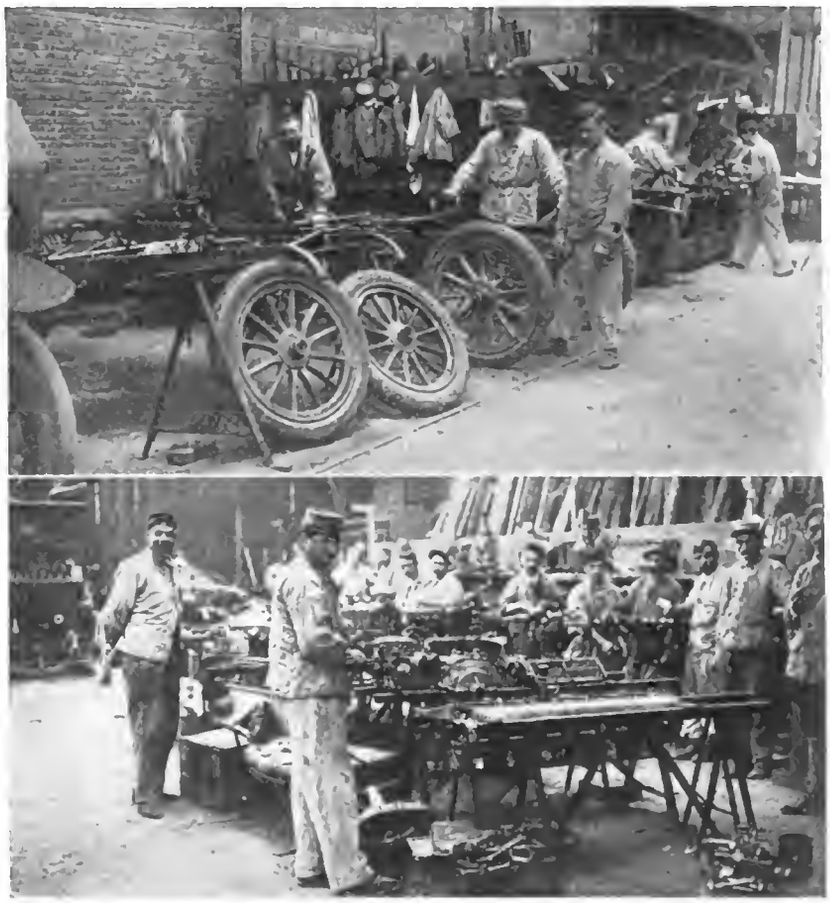
In the center of the next group is a touring car with its rear axle jacked up and its front wheels locked. Here the men are learning both to crank the engine and to change gears, the latter operation being one of the most difficult the instructors have to inculcate. The gearbox cover is removed

A few of the many touring cars awaiting repairs at the shops

and for the first attempt the pupil is allowed to watch the revolving gears. As soon as he has realized that the object of the change speed lever is to put into engagement sets of gears of different diameters, it is insisted that he make all changes with his eyes on the road ahead.

Following the gear-changing classes there are two others dealing with pneumatic tires. It is a fact that a large proportion of the pupils are not aware that a pneumatic tire comprises an outer casing and an inner air tube. This is explained to them, and also the manner of mounting and demounting tires and inflating them to the correct pressure.

These three classes, dealing with elementary automobile construction, gear changing and tire manipulation, are obligatory on all pupils whether they are going to be drilled into expert motorists or by reason of their mediocrity are destined to be transferred to the separate truck school. Other and more advanced classes deal with the theory and construction of carbureters; still another handles the problems of ignition by high-tension magneto, battery ignition evidently being ignored in this school. In another class gearbox design and gear ratios are dealt with, and still further along the interest is centered around rear axles.



Above—A crew of three mechanics engaged on touring car repairs. Below—A scene in the touring car repair shops

Indoors and Outdoors Each Day

The working day is divided into two groups: the men who have been in the open-air classes in the morning spend the afternoon on the road, while those who began the day with driving are given theoretical instruction in the afternoon. This method of alternating theory and practice is found to be most conducive to rapid progress. Four men and an instructor are put aboard each car, the school machines comprising practically every known French make, together with a sprinkling of foreigners. The men do not adhere to any one car during their period of instruction, but change practically every day, so that from the outset they become habituated to different types of control.

During the elementary stages of their instruction the cars are confined to a 5 or 6 mile circuit comprising dead level roads with plenty of by-lanes. Straight ahead driving is not encouraged, the man being constantly called upon to turn, reverse, stop, start, and go through the train of gears. Each man takes his turn at the wheel while the three others listen to the criticisms and advice of the instructor.

After some skill has been acquired in the handling of the steering wheel and the levers the men go out in convoys over give-and-take roads mostly of a hilly nature, the entire convoy being in charge of an officer. As they near the end of their course the men are put on faster cars and every day each man gets about 30 miles actual driving on a machine capable of 60 m.p.h.

No driver is considered competent until he has spent two weeks in the repair shops, forming a team with a couple of skilled mechanics. Night driving tests have also to be successfully passed, these, of course, being undertaken without any lights on the cars and over unknown and unlit roads.

A Practical Test

The army touring car driver must be capable of all kinds of running repairs, and of getting his car going again after a breakdown, in the shortest possible time. As a test in this connection, the driver goes on the road in company with an underofficer, and during the trip his car is disabled. On the skill shown by the man in getting his car back to running condition will depend the number of points given him in the examination. Most of these men, when sent to the front, will have to carry officers, or may be intrusted with important messages to be delivered to units in the field.

Every week a certain number of men leave the school for a central automobile depot from which they are allotted to the armies in the field requiring their presence. Generally on entering the school their military equipment is incomplete, but on leaving that institution they are uniformly dressed in the light blue uniform of the active army; with a steel helmet, a red badge with the letter A on the right arm—signifying "automobile"—a kit bag over one shoulder and a rifle over the other, they go forth to active service. For a large proportion of them there is no novelty in going to the front, for these newly formed drivers are old soldiers who have been wounded and rendered incapable of further service with the fighting forces. It is a general rule that men shall not be admitted into the army automobile service if they are physically fitted for the firing line.

Repairing Pneumatic-Tired Cars

In connection with this school there is a huge repair department for all kinds of pneumatic-tired automobiles used in the various services behind the lines. No trucks, or any kind of vehicle running on solid rubber tires, are handled in this section, and although generally known as a touring car repair depot, a more correct designation would be pneumatic tired automobile repair department, for ambulances and light vans form a sprinkling among the touring machines.

There is more variety in this repair shop than in any automobile establishment in any part of the world. In addition to a score of modern types of well known French makes, the

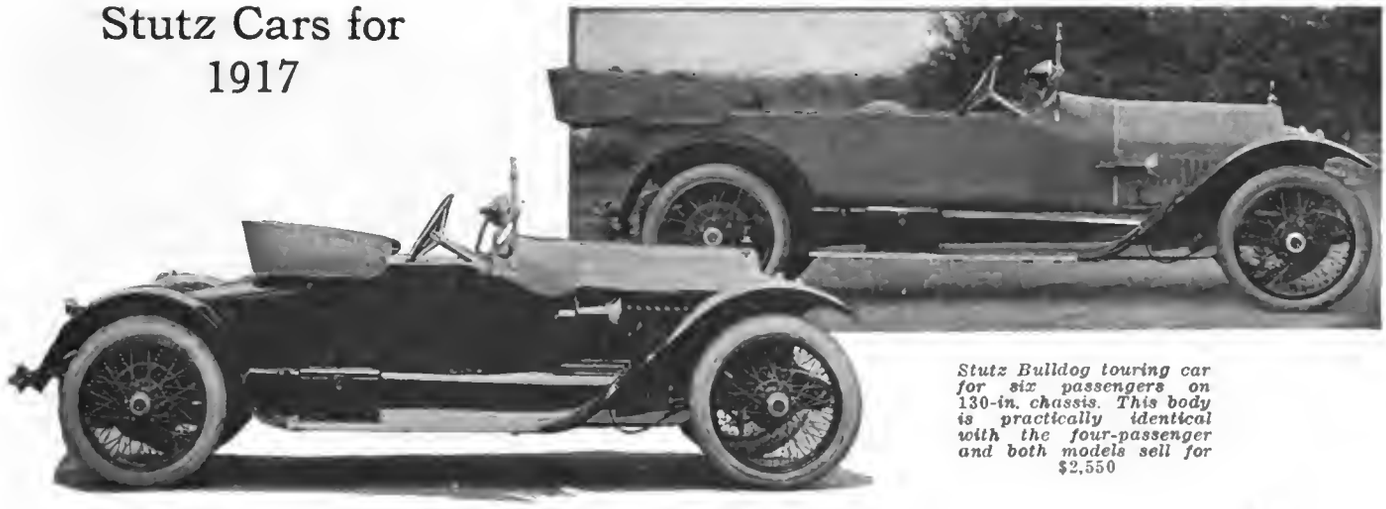
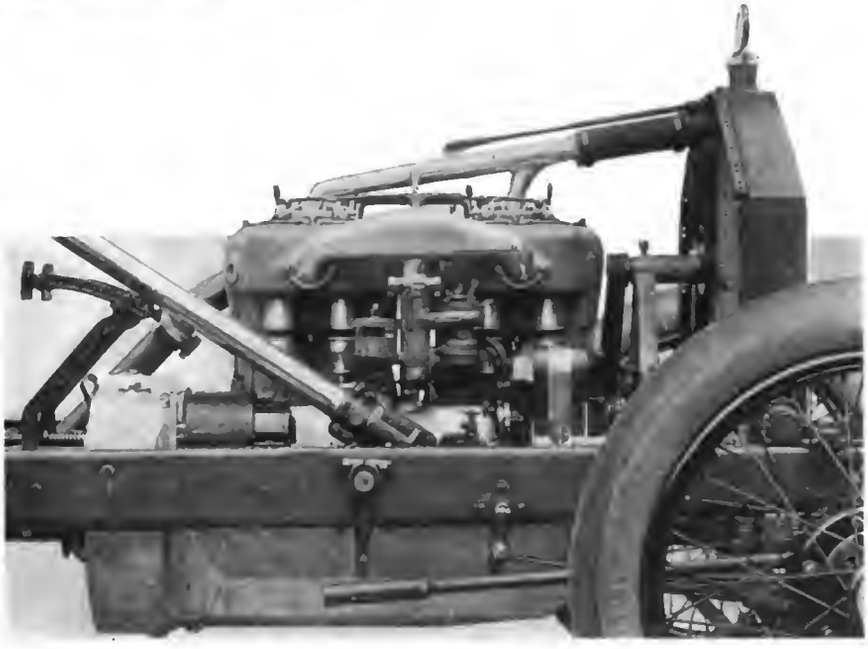
Stutz Cars for 1917



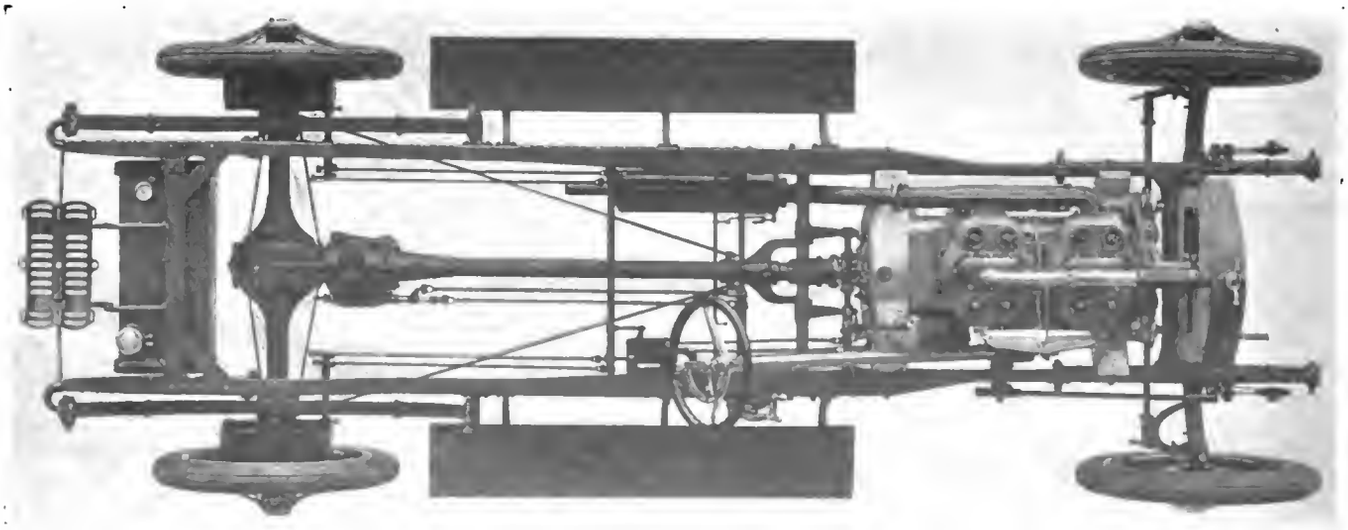
Stutz Bulldog touring car for six passengers on 130-in. chassis. This body is practically identical with the four-passenger and both models sell for $2,550

New Stutz roadster with rear deck and tank carried on the rear of the frame. Carrying space is provided beneath the seat and under the deck

Rear of roadster, showing spare wheel on deck. This view also gives an idea of the smooth, rounded fenders and the gasoline tank mounting



Intake side of Stutz engine for 1917. The carbureter is the only important change, being designed to take care of the low-grade fuels now so largely in use. Note new arrangement for preheating gas. Hot water jacketing is also used to take care of heavy fuel



Stutz touring chassis, showing that, in spite of the high-powered engine, simplicity has not been forgotten. Note, for example, the manner in which the frame ends are curved over to form the rear spring supports. The engine has four 4¾ x 5½-in. T-head cylinders with a formula horsepower of 36.10. Note the three-speed gearbox mounted on the rear axle and the spare tire carrier. The rear springs are 6 in. longer than in the previous model

Easier Riding New Stutz Feature

Longer Wheelbase and Springs—New Roadster Body—Improved Carbureter Layout To Suit Heavy Gasoline

THERE are few changes evident in the new Stutz chassis. A water-heated intake manifold and a hot air supply to enable the heavier grades of gasoline to be used are new features. Next is a change in the wheelbase, which is now 130 in. on all models, and an increase in rear spring length.

Three Models in 1917 Line

The range of models now includes the four and six-passenger Bulldog specials and the new roadster. The Bulldog models have a little more room in the bodies, and the roadster is entirely new in body equipment.

The price of $2,550 for the Bulldog is the same as on the previous model, while the new roadster price, which is $2,275, is an increase over the previous model justified by a longer wheelbase and a great number of refinements.

The only change in the power plant is in the location of the carbureter and manifold and the new facilities for heating the gases. The new manifold has a waterjacket of unusual capacity, which is connected over the top of the engine by a short pipe directly to the water-exit pipe which leads to the radiator. Not satisfied with this method of heating alone, the Stutz designers have installed a flexible hot-air tube from a stove on the exhaust manifold which leads between the two cylinder blocks to the air intake in the carbureter. This construction not only permits the entrance of heated air into the mixing chambers of the Stromberg, but also eliminates the chance of condensation of the gases by their passing through a hot manifold before entering the motor.

The new carbureter location is several inches higher than that of the previous models, making the instrument very accessible. The frame has been increased in size. The side bar is now 5 in. deep, with a 3½-in. width in the center gusset plates which are integral with the side bar. The rear of the frame is now extended to form a spring hanger by the use of U-shaped forgings instead of the goosenecks previously used.

Straight Line Drive

An alteration in the chassis design which not only makes a much easier riding car but permits a straight-line drive through the double universal joints is the increase in length of the rear springs from 50 to 56 in. and so changing the design that when the car is loaded these springs lie perfectly flat. This, together with the Hartford racing type shock absorbers, which are used as regular equipment on all models, and the characteristic Stutz feature of unusually low center of gravity in the body and seating of passengers, makes the new car by far the most comfortable riding proposition which the factory has yet produced.

In speaking of the new Stutz bodies, of course the brand-new roadster is the most interesting because of its newness. The body is placed on the standard 130-in. wheelbase, whereas all previous Stutz roadsters were on a 120-in. wheelbase. In the place of the combination oil and gas tank and traveling trunk evident on the old roadster, the new car has a modified turtle-back rear with a depression, circular in form, for carrying an extra wire wheel and tire. The wire-wheel carrier provides a very substantial support; in fact, the wheel is fitted onto lugs much as it is when it is in place on the axle. With the addition of a special padlocking device for safety, the spare wheel is placed so firmly that there is no chance of its vibrating.

There is a carrying space in the rear of this body, directly in front of the spare wheel space and behind the seat, which is large enough to hold two or three suitcases. Entrance to the compartment is gained through a large door on the top, which is locked by a key on both sides.

Body Is 4 In. Longer

The body length of the touring car has been increased 4 in. and the width 1 in. The increase is all taken up in the rear compartment, so that ample leg room is provided both for the passengers in the auxiliary seats and in the rear seats. The bodies of the four-passenger and the six-passenger are identical, except that in the latter folding auxiliary seats are substituted for the cowl cabinet and Thermos bottles, which in the four-passenger are carried as regular equipment.

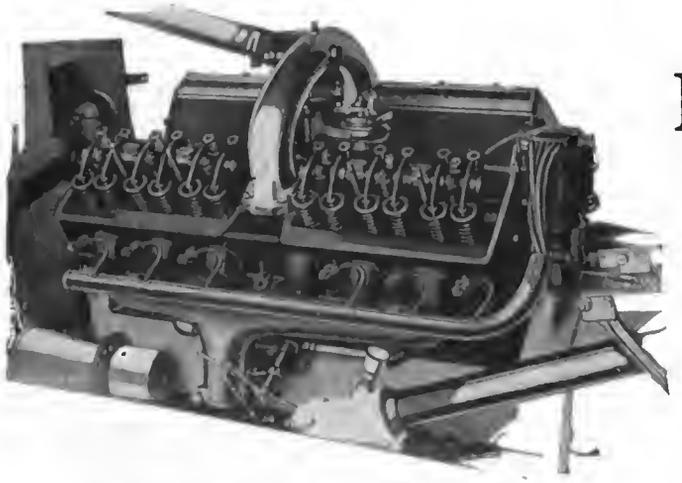
The engine is a four-cylinder, pair-cast, T-head design, 4¾ by 5½ in., with three bearing crankshaft and camshafts. The leather-faced cone clutch and the characteristic Stutz rear axle gearset which have been used by this company since its inception are unchanged. As in previous models, the camshafts operate roller-type pushrods and the valves, which are tungsten steel, 2¼ in. in the clear, have the mechanism inclosed by individual housings. The camshaft is by helical gearing. Lubrication is by force feed through a hollow crankshaft, carburetion by a Stromberg, and ignition by Bosch double-distributer magneto, with a Remy system taking care of starting and lighting.

In the gearshift, however, there is an alteration in that the shifting lever positions are reversed to what they were on previous models. With the former construction the high-gear position was on the inside and toward the driver. This position was slightly inconvenient, inasmuch as the lever was in the way of the driver's leg. The change has been made, as stated above, by reversing the shifting positions so that now the lever when in high is against the body and out of the way. A padlock for locking the shifting lever in neutral has been added.

Pedals Are Adjustable

The pedals may be adjusted to suit the driver's requirements, there being a variation length of 2½ in. There is an inclosed propeller shaft, the torque tube surrounding it being attached to a face plate back of the clutch.

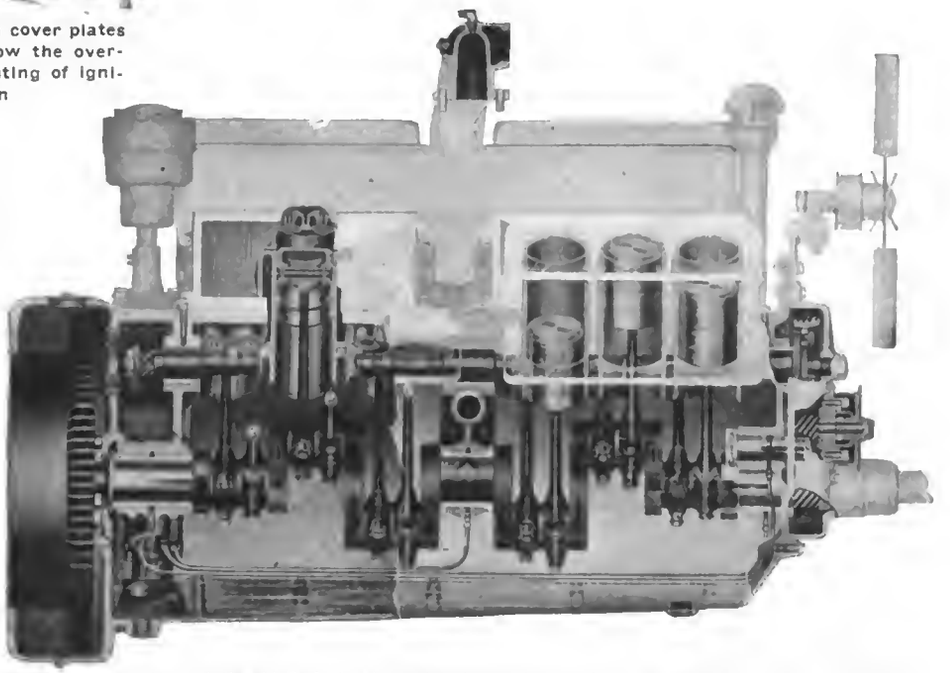
Upholstering on all new models is either brilliant-finished, long-grain, hand-buffed black leather or dark brown Spanish hand-buffed leather. The fenders are now slightly crowned, which adds to the appearance of the assembly. Battleship-gray and Mercedes-red are the new standard colors. Stutz has departed from the use of wood wheels altogether and will furnish Houk wire wheels in one size, 34 by 4½, one extra wheel going as regular equipment without additional cost. In tires, an option of either Goodrich Silvertown cord or Goodyear cord is offered. Accessories include a Boyce Moto-Meter, windshield spotlight and double-bulb lamps, with the small bulb out of focus to comply with dimmer ordinances.



H-A-L twelve-cylinder engine, with cover plates removed from the left block to show the overhead-valve mechanism. Note mounting of ignition distributer and horn

H-A-L Twelve Now In Production

Overhead-Valve Engine 2⅞ by 5 In.—135-In. Wheelbase, Straight Taper Frame and Body Lines with Rounded Top Edge



Phantom view of the H-A-L twelve, showing side by side connecting-rod mounting for which the cylinder blocks are offset 1½ in. The oil lead connections, camshaft and distributer drive are also illustrated

EMBODYING a 2⅞ by 5-in. twelve-cylinder unit power plant, a three-speed gearbox and floating rear axle, the H-A-L car sells for $2,100 as either touring car or roadster. Although the car was announced some time ago, the H. A. Lozier Co., Cleveland, Ohio, has only recently begun production and the complete details of the cars are now available.

Body fashion designers have approved the straight taper from radiator to rear of car, with no break at the hood; they have said that the cowl effect at the back of the front seat is good form and also made it clear that the top edge of the body must be rounded over. The H-A-L exhibits all of these fashionable curves, and as its wheelbase is 135 in., there is ample room for carrying out the smooth, sloping lines. At the present time two body types are offered, these being the seven-passenger touring car and the roadster.

The H-A-L has an overhead-valve twelve-cylinder engine with a bore of 2⅞ in. by a stroke of 5 in., the drive being taken through a disk clutch, three-speed gearset and open driveshaft fitted with two universals. The final drive is a Timken floating axle, and the rear suspension is by semi-elliptic springs. The frame is a straight tapered affair reinforced by four large cross members, and the tires are 34 by 4½.

The Engine in Detail

The engine develops, according to formula rating, 39.6 hp., but this is merely a nominal figure, for it is claimed that the engine will deliver 70 hp. at 2000 r.p.m., and that the maximum is well over 90 hp. The dimensions give a displacement of 389.6 cu. in.

In its general arrangement, the power plant is of the type in which the cylinders are cast in two blocks of six. Practically the only thing between the blocks is the carbureter, which is a commendable construction. The overhead valves are inclosed by cover plates, four in number, each housing the valve mechanism for three cylinders.

On the right side are the starting motor, the generator and the water pump. Thus only one extra driving gear is required besides the timing gears. The fan is driven by a pulley on the front of the generator and water pump shaft, and at the rear of the crankcase just back of the cylinder blocks is the vertically-mounted ignition distributer. This is driven from the rear end of the camshaft by a helical gear. The position of these units leaves ample room for the exhaust manifold for the right block.

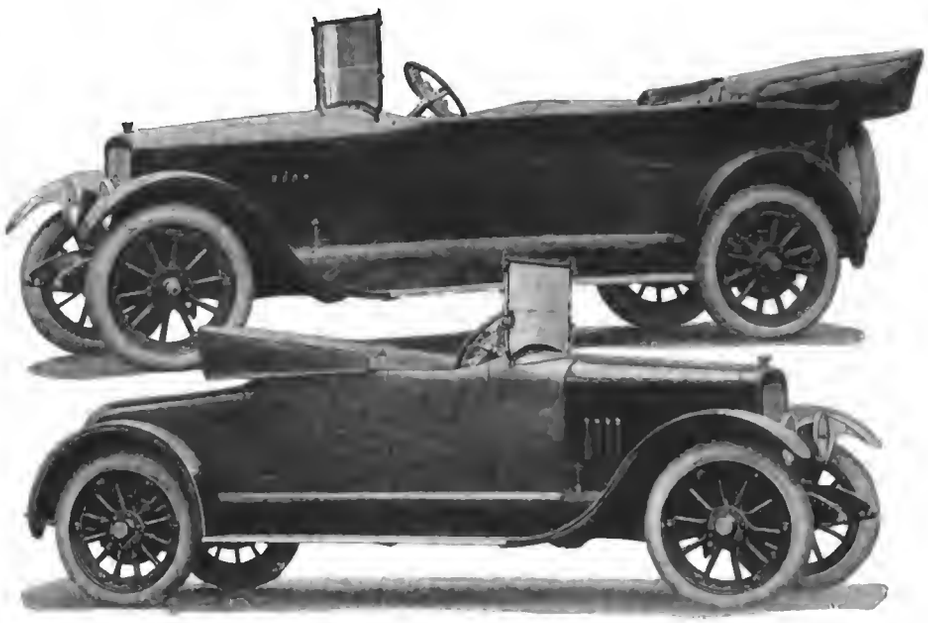
Cylinder Blocks Offset

The cylinder blocks are arranged with a 1½ in. offset from one another with side-by-side rods. The three-bearing shaft has a diameter of 2⅛ in., which when it is considered that the bore is only 2⅞ in., appears to be an exceptionally large shaft for a motor of this size. The camshaft is mounted also on three bearings, and is positioned directly above the crankshaft, so that it actuates all of the valves directly. Due to the fact that the cylinders are offset, it is possible for each tappet to have its own individual cam, which construction simplifies the lower valve construction and allows for synchronized valve timing, since it is not necessary to consider more than one valve in the shaping of each cam. Pistons are quite long and have chamfered heads which should assist in keeping the oil down out of the combustion chambers, since there is a tendency of the lubricant to ride by the piston head instead of being scraped into the combustion chamber as might be the case if the upper edge of the head were not of this beveled form. In addition to

the top rings there is one ring near the bottom which acts as a wiper. The pistons are cast iron.

Pressure Oiling System

An elaborate oiling system has been provided for the engine with the oil pump in the crankcase forcing a constant supply through individual pipes to each of the three main bearings and also to the camshaft bearing. The connecting-rods are oiled from the main bearings through holes drilled in the webs of the crankshaft. There is sufficient oil thrown off from the sides of the connecting-rod lower ends to lubricate the cylinder walls, this oil being virtually a vapor, due to the rapid revolving of the crankshaft. A special lead runs to the timing gears and the oil breather and filler pipe is mounted at the front of the motor, directly ahead of the left cylinder block, being brought up high enough so that filling is very convenient and spilling oil minimized.



H-A-L touring car and roadster which are mounted on the same chassis with 135-in. wheelbase with twelve-cylinder power plant. Both models sell for $2,100

This engine is arranged so that the water outlet connection is combined with the intake manifold, which bridges the gap between the cylinders and from which the carbureter is suspended. Thus the heated water from the cylinders passes around the inner pipe which carries the fuel to the cylinders and good vaporization of the gas results. As before stated, the water pump is mounted on the right side back of the generator. Besides introducing the water into the immediate block of cylinders, the pump also sends a supply across through the crankcase to the more remote block and the design is such that each set of cylinders gets equal cooling water. The belt-driven fan is mounted on a bracket attached to the crankcase and there is a simple adjustment for the belt tension.

Electrical System Arrangement

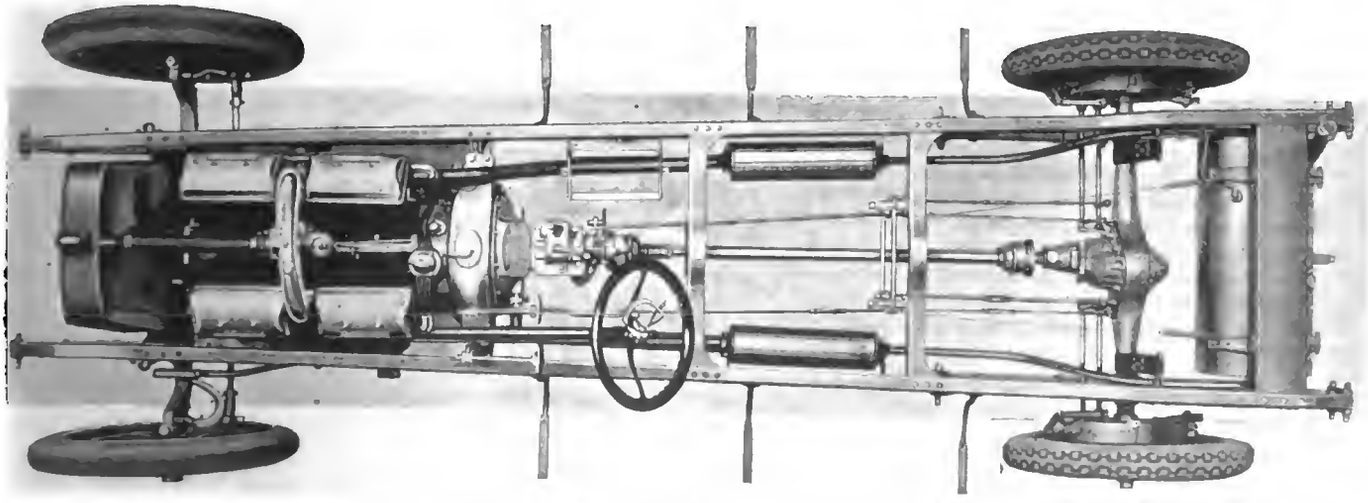
Electrical units for starting and lighting are Westinghouse and these, together with the Remy distributer, utilize a 100-amp.-hr. Gould storage battery, carried on the right side of the chassis and reached through the floorboard of the front compartment. The location of the distributer is such that the ignition wires running from the spark plugs are quite short ,and as the plugs are mounted on the outside of the cylinder block, wiring manifolds are fitted which prevent the wires falling down on the exhaust pipes below them. The starting motor drives through gear connection with teeth cut in the flywheel rim in the usual way.

Compactly attached to the rear of the crankcase are the multiple disk clutch and three-speed gearsets, the bell housing of which completely incloses the flywheel and clutch mechanism, as well as carrying the brake and clutch pedal shafts.

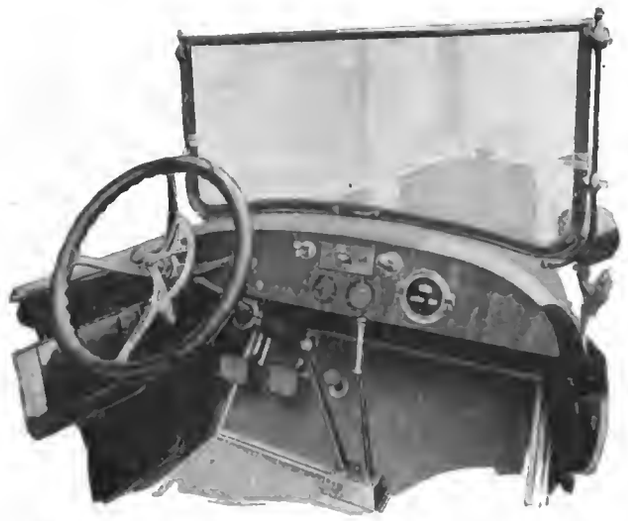
The clutch is a dry disk type made up of one steel disk and two of Raybestos, all three being 12 in. in diameter and having a face width of 1¾ in. Gears and shafts in the gearset are made of nickel steel and mounted on S. K. F. annular ball bearings. On the left side of the gearcase is mounted a single cylinder tire pump which is driven by one of the countershaft gears meshing with the pump gear. To throw the pump into driving engagement, there is a key located in the floor in front of the driver's seat. Then just back of the gearbox on the driveshaft is mounted the speedometer driving gear, meshing with the flexible speedometer shaft gear which is bracketed to the back side of the gearcase.

Floating Rear Axle

The drive is through a propeller shaft of nickel steel tubing, having a 2 in. outside diameter and a wall thickness of ¼ in. The rear axle unit is a Timken floating construction,



H-A-L twelve chassis, showing neat layout of power plant, double exhaust lines, straight taper frame and mounting of fuel tank at rear. Note combined water outlet and intake manifold bridging the V between the cylinder blocks



Driver's compartment of the H-A-L, showing control members and symmetrical arrangement of instruments on the cowl board

fitted with spiral bevel driving gears and all carried on Timken roller bearings. The axle housing is a steel pressing with axle tubes in unit with the differential case. A large plate at the rear gives complete access to the differential gears and driving gears for adjustment or repair. The axle affords a ratio of 4 5/11 to 1.

Long, flat rear springs of semi-elliptic form are fitted, these being underslung from the axle and taking a flat position under load. They consist of ten plates, 2½ in. wide and are 57 in. long. The tapered frame narrows at the front in order to give a small turning radius, and a firm body support throughout the entire body length as well.

At the rear is mounted a 23-gal. gasoline tank, suspended by steel straps from the rear cross member. Fuel is fed to the carbureter by the Stewart vacuum tank arrangement.

In connection with the outward appearance of the car, mention should be made of the distinctive type of radiator used, which is moderately high and narrow and which blends well with the general sloping lines of the car. There are auxiliary tonneau seats which fold into the back of the front seat, and another attractive feature is the symmetrical grouping of the instruments on the board.

Gray & Davis Electric System for Fords

GRAY & DAVIS, Boston, Mass., have just brought out a double unit starting and lighting system for Ford cars to sell for $75. Electrically the characteristics do not vary from previous Gray & Davis practice. The system consists of a motor and a generator which are electrically separate, but which are inclosed in the same housing, lighting and starting switches and a complete outfit of wiring and sprockets, etc., to make a complete installation.

Simplicity is the keynote of the new apparatus and it is designed particularly to appeal to the average Ford owner who desires to fit his car with full electrical equipment. It is intended for use on even the latest Fords, for, although these have electric light, there is no battery and the headlights are not available unless the engine is running. With this system the layout includes a full battery and charging apparatus.

A shunt-wound dynamo is used and this is connected to the crankshaft by means of a sprocket and silent chain. The chain width has been made particularly large for long life and also for silence. The regulator is a magnetic type and includes the automatic cut-out.

Located above the dynamo is the starting motor. This is a straight series-wound machine which is featured by a Bendix gear meshing with the dynamo sprocket wheel to crank the engine. The series-wound motor, in conjunction with the Bendix arrangement, gives a very simple mounting, especially in that the driving units do the work for both the starting motor and the generator as shown very clearly in the illustration herewith.

The fittings and materials have also been given close attention. The framework, for example, is forged from alloy steel and the end or bearing brackets are electrically welded to the frame. An enameled steel box is used to carry the 6-volt battery and there should be no clumsy wiring on the car, as the wires and cables are all cut to proper length and furnished with the outfit. The supporting clips and terminals are also provided.

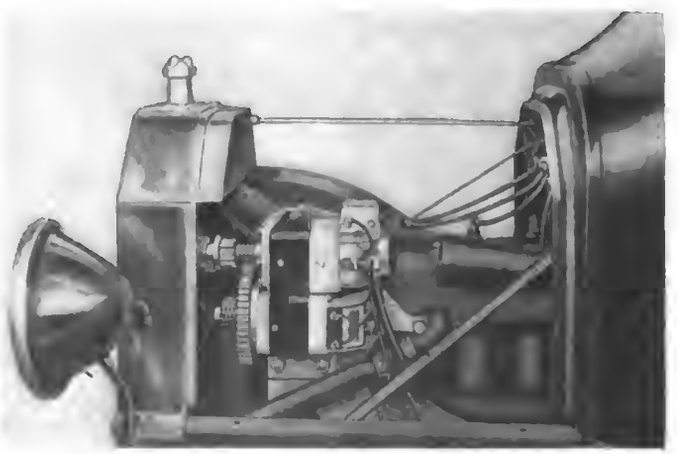
In making the installation the only part removed from the engine is the pulley on the crankshaft which is replaced by the sprocket. Even the starting crank can remain in position if desired. The framework bolts in place and is simple to mount, although when in place, the entire assembly is very rigid and well able to sustain the torque reactions in turning over the Ford motor.

The wiring layout is conventional, the battery floating on the line and thus acting as a pressure regulator, keeping the flow steady in spite of the rate of speed. The generator is capable of carrying the full lamp load at comparatively low motor speeds and is arranged to cut in at a car speed of close to 10 m.p.h. This is the speed at which the units on larger cars operate and it is found that for the average driver, the battery will be kept fully charged if more than a normal amount of night driving is not indulged in.

Carrying Spare Bulbs

THAT so few automobile manufacturers provide proper means for stowing away the necessary spare bulbs for the headlamps and tail lamp is rather remarkable. There are now a good many cars in which there is a fuse assembly back of a panel in the cowl board, giving access to all the fuses when unlocked and opened. Surely the spare bulbs could more often be carried behind a similar panel, each fitting in a dummy lamp holder, as in the Franklin car.

Inside the panel it would be a good idea to have a printed notice, stating the type and make of bulb for which the lamps are adjusted and the sort of filament which suits the reflectors. Such a precaution would prevent the use of unsuitable bulbs which is a common cause of glare and of poor driving light.



Latest Gray & Davis Ford starter, showing super-imposed starting motor

Advantages of Caterpillar Tractors

Special Work Can Be Done by This Type Which Wheeled Machines Cannot Accomplish—Type Worthy of Development—Automobile Engineering Experience Would Effect Vast Improvements

Part II

PREVIOUS reference has been made to the width of round wheels in some of the earlier steam engines built for work on peaty ground, and in the early days the driving wheels were made as wide as 12 ft. on either side of the engine. The standard width of caterpillar track is 24 in. and the wide track is 30 in. for the 75-hp. machine, but as the length of the track is 67 in. on each side of the machine, it will be seen that the specific load is 7 lb. per square inch of projected area with a 24 in. wide track. The weight of the machine being 23,500 lb.

Useful in Great Cold

That the caterpillar is not confined in its operation to temperate countries but is able to work under conditions of extreme cold is shown by the work accomplished in Alaska at a temperature of 40 deg. below zero Fahrenheit where timber has to be hauled for a distance of 9 miles and is used for fuel. The wood is hauled by team from where it is cut to the river and then loaded on sleds, from 5 to 8 in number, and hauled down the frozen Tanana, which is a branch of the River Yukon. Thirty cords of wood are hauled at one time in this way at a profit of about $5 per cord, the operating cost being $60 per day. Some of the peculiarities of the local conditions may be summarized as follows:

The extreme cold makes the snow dry and yielding so that the steel runners do not readily slide over it. It is therefore impossible to start the train with the full load after it has once stopped, and in order to get over this difficulty, the following method is adopted:

The caterpillar is first backed into the train of sleds and each one jolted back far enough to leave slack in the chains between all of them. The caterpillar is then started forward with a jolt and each sled in turn started with another jolt. In spite of this severe usage, the caterpillar has been at work satisfactorily for four years and is likely to continue some time longer. The only breakages up to the time of writing have been a few valve brackets and one large cast iron bevel gear. The intense cold renders the cast iron brittle.

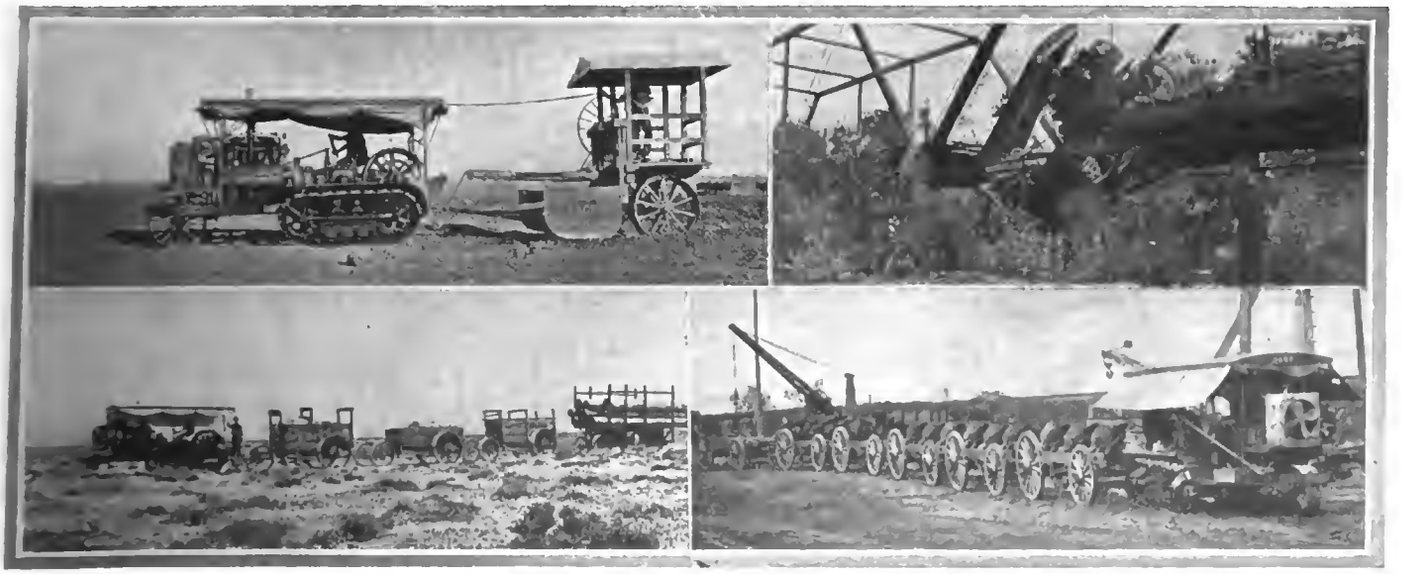
In order to adapt the machine to the climatic conditions a crude form of radiator made of half inch pipe was substituted for the standard radiator and the fan was eliminated. Extra adhesion is obtained by welding a large chain around each shoe.

The fuel used in the engine is distillate at temperatures down to 25 deg. below zero, but when the temperature drops below this, gasoline is used, as well as for priming the engine before starting. It is stated that no trouble is experienced in starting the machine from cold in any weather.

Can Haul Lumber

An example of the caterpillar working under difficult conditions of another type may be mentioned from the logging industry. From a report on the performance of a 60-hp. caterpillar covering 3 years' work hauling shingle bolts, making four and sometimes five round trips a day on a 2-mile haul, we obtain some idea as to the arduous character of the work involved.

These shingle bolts are hauled by the caterpillar over a skid road made up of cross ties and planking, with a row of logs down the center. The sleds on which the bolts are loaded, straddle across the center row of logs, which prevent the sleds slipping sideways on the greased ties. The par-



Upper left—Caterpillar tractor hauling a land leveler. Right—Precipitated 13 ft. into a river by the breaking of a weak bridge, this caterpillar went home under its own power. Lower left—Caterpillar in desert freight work. Right—Outfit owned by a gold-mining concern, another example of the caterpillar's hauling abilities

ticular machine engaged in this operation differs slightly from the one used in Alaska, by reason of its being provided with two front wheels, to enable it to straddle the center logs. Three sleds are pulled at once, each one hauling 4 cords of shingle bolts weighing 3500 lb. to the cord. The 2 mile road is on an uphill gradient, part of which is 12 per cent, and the load is never less than 20 tons. Work of this nature can be performed by the caterpillar more effectually than by any other type of hauling machine, as the irregularity of a wooden or corduroy road in no way affects the operation of the machine.

References have already been made to the work of the caterpillar in leveling land, and a land leveler being operated for this purpose is shown on page 229. In much of the Western country it is necessary to pull the stumps of trees before the leveler can be got to work, and as an example of what the caterpillar can do, the following may be cited:

Pulling Old Stumps

In a certain district the trees had been cut, many of them being as much as 8 ft. diameter, but the stumps were left in the ground and sugar cane was planted with the aid of pick-axes in the field thus partially cleared. The ground was quite soft and the surface uneven, so that it was just a question as to whether a tractor could be used for pulling and hauling these stumps. A period of eight years had elapsed between the time of the trees being cut and the time of the attempt to pull the stumps by caterpillar power, but this was eventually tried and a ¾-in. diameter steel wire rope was attached to the trees in turn, as it was found that chains which had been previously tried snapped in two. The uprooting was done by a steady pull, and owing to the roots being even at that time firmly fixed in the ground, 1½ to 2 cu. yd. of earth came away with each stump. A good day's work for two men with the caterpillar was twenty-five stumps.

In addition to leveling open country, the grading of roads forms an important occupation for the caterpillar, and in competition with traction engines we will take an example where a mile stretch of land between two irrigating ditches about 45 ft. apart was chosen. Seven tractors, in addition to one caterpillar, took part, and the first machine was occupied for more than half a day grading 150 yd. Another machine graded 150 yd. in 3½ hr., and again the fifth machine required 4 hr. and 20 min. Some of these tractors wasted a considerable amount of time in turning, which operation required from 7 to 12 min. in some instances.

When the caterpillar came along, it completed its work in 2 hr. and 5 min., and then went straight ahead and graded another 350 yd. in 1 hr. and 42 min. Not satisfied with this performance, the caterpillar representative picked out a stretch of gumbo land that was admitted to be the worst in the country, and it finished half a mile in 2 hr. and 12 min. During this exhibition the consumption of fuel was 11 gal., of track oil 1 gal., of lubricating oil 1 pint, and no perceptible water.

The caterpillar will stand some rough usage, as illustrated on page 229, depicting what occurred when a very weak bridge collapsed, precipitating the machine a distance of 14 ft. into a river. The bridge in question had been condemned for some time, but the driver of the caterpillar was of the opinion that the large distribution of weight which is afforded by the caterpillar tracks would be a sufficient safeguard against an accident of this kind happening. He was, however, mistaken, but the caterpillar did not suffer any damage as a result of this fall. The front end of the caterpillar was gently lowered to the ground and the engine re-started and run home under its own power, no parts being broken except a casting on the steering gear.

Future Is Promising

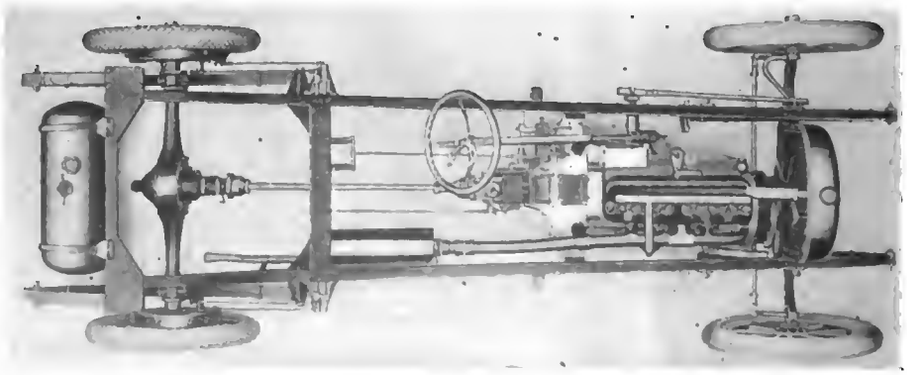
Some time ago an American farm power journal published an article and graph showing the percentage of slipping of round wheels on a tractor engaged in plowing, and the data was based on the performance of a 20,000-lb. tractor operating in an average field with standard cleats on its wheels. This curve showed that the slip when hauling four plows was 2 per cent, which increased to 5 per cent when seven plows were hauled. With an increase of loading up to ten plows, the slip was 20 per cent, and with twelve plows 38 per cent. There are, of course, certain conditions of ground surface when the tracks of a caterpillar will also slip, but these are not frequently met with. When the surface is hard and unyielding, such as closely fitting boards, stone setts or cobbles, the caterpillar tracks will sometimes slip rather than allow the load to pull up the engine, and in freighting on this type of road some care has to be exercised by the driver in the event of one track operating on a different type of surface from the other track, as there is a tendency under these conditions for the caterpillar to slew round.

Working on a hard surface is one of the most severe tests of the caterpillar, by reason of the vibration which is set up in the machine and particularly in the track. Under no circumstances, therefore, when reliability and endurance is aimed at, should a caterpillar be run at more than 2 m.p.h. At such a speed its economy is at maximum and the rate of fuel consumption of a 75 hp. machine will be about 2¼ gal. per mile.

Some Troubles With Track

Actual practice has shown that on hard roads there is a very considerable difficulty in keeping the bolts in the track tight, and these not only stretch and shake their nuts loose but they appear to jar themselves down onto the metal surface of the track plates and a general looseness results. Another difficulty which develops in the track is the breaking of track bolts under heavy vibration, but this is not insurmountable, and resolves itself into a matter of material and design. The above difficulties do not manifest themselves under the conditions of working for which the caterpillar was originally intended, namely working on soft ground.

In conclusion, although the caterpillar is in its infancy as a mechanical appliance, regarded in the light of other methods of haulage and locomotion, its performance over a large variety of heavy duties has proved so remarkable that great hope can be held out for its future development. It has amply proved that it can carry out successfully difficult duties which cannot be attempted by any other type of machine, but it suffers from lack of that detailed development and advanced design of which it is worthy.



Chassis of the Velie small six, showing clean layout and the taper frame construction

Velie Improves Appearance

New Body Styles of Handsome Proportions—Chassis Practically Unchanged—Range Includes Small and Large Sizes

THE Velie has always been a car of distinctive character, and a car built with somewhat more than usual regard for the little things which make for satisfaction. The new models just announced by the Velie Motor Vehicle Co., Moline, Ill., are no exception in this respect, rather they are even better in detail quite apart from the new bodies which are really distinctive. The touring cars now have the top edges of the doors and side panels well rolled inward, instead of finishing with a square edge, the lines are straighter and the whole exterior smoother. Also it should be remarked that these bodies are of rugged construction. The doors shut with the feeling of solidity always noticeable on a custom built job, the seats are deep with good depth of padding at the backs and the proportions are such that an easy sitting position is obtainable either in the front or rear compartment. For the driver there is distinctly more room than usual and the pedals have a wide range of adjustment to suit any stature.

One of the most striking of the new models is a four-passenger roadster which has a long deck back of the rear seat. The deck is carried along the sides of the rear seat, which is a little narrower than the full width of the body, so that the seat sides stand up something like the combing around the seating of a motor boat. As the deck slopes from front to rear the effect is quite distinctive, catching the eye immediately.

Another body style which the Velie company expect will be in strong demand is a French model of town car, and there are several other styles as well.

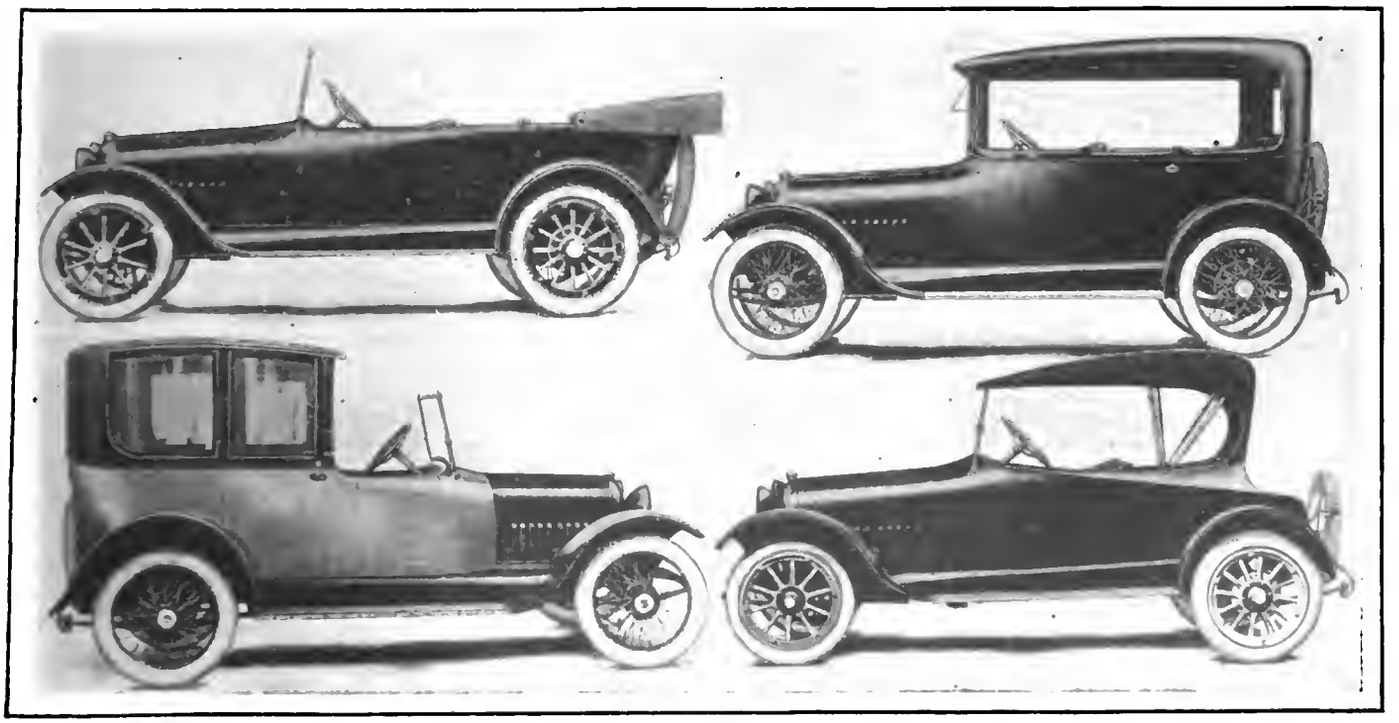
As for last year, there will be two chassis, both sixes; the smaller being made in the largest numbers. Both have Continental six-cylinder engines, the smaller 3¼ by 4¼ in. and the larger 3½ by 5¼ in. An innovation for Velie is the use of Timken axles front and rear. Both power plants are the unit type, the smaller car having a three speed transmission and the larger four speeds with the high gear indirect. Dry disk clutches are used for both cars.

Velie was one of the first to adopt the taper frame with the side rails perfectly straight from end to end, and this is being used for both 1917 cars, three-quarter rear springs and Hotchkiss drive being two other features which are likewise unchanged. Lighting and starting is cared for by a Remy outfit, the generator having the ignition distributor combined with it. A feature of this system is its small size and weight, and the Velie engineers have arranged the generator so that it is very accessible.

Wide Choice of Bodies

Tabulating the different body types offered is the easiest way of emphasizing their variety. On the large six there is only one style, this being a seven-passenger touring body. The wheelbase of this model is 124 in. and tires 35 by 4½ in. On the smaller chassis which is 115 in. wheelbase and has 32 by 4 in. tires, non-skid on rear, the bodies available are as follows:

Touring, five passenger	$1,085
Roadster, two passenger	1,065
Roadster, four passenger	1,085
Coupe, four passenger	1,750
Town car	2,200
Touring sedan	1,685
Cabriolet, two passenger	1,485



Upper left—Large "Biltwell" Velie six with seven-passenger body. Below—The French type town car on the smaller chassis. Upper right—Convertible touring sedan with detachable windows on the small chassis. Below—The new four-passenger roadster

Getting Correct Front Spring Action

Possible Methods of Mounting Automobile Front Springs Which Will Eliminate Front Wheel Wabble and Interference with Steering Caused by Road Shock

By H. H. Dyke

IN a letter in Forum some months ago certain disadvantages of the standard type of front spring construction were pointed out and it was shown how these disadvantageous features arise from causing the front semi-elliptic spring to turn on a fixed pivot at its forward end, *ahead* of the front axle, and connecting the steering link to its steering gear arm some distance *behind* the front axle, bringing these two pivoting points on opposite sides of the axle so that they tend to move in divergent and conflicting arcuate paths.

What is needed to cure these defects is to get the centers on which the steering link and the front axle (with the steering knuckle arm secured to it) turn, close together, instead of as far away from one another as possible, and then there will no longer be the divergence between the paths in which these parts tend to turn and which give rise to "drunken" movements of the front wheels, wear on the front tires, steering gear wear, turning of the steering wheel in the driver's hands, and numerous other things which are wrong and could be avoided.

Reversing the Connections

A simple change leading in the right direction is illustrated in Figs. 1 and 2, in which the connections at the ends of the front spring are simply reversed from the ordinary practice, Fig. 1 showing a push shackle, and Fig. 2 the more desirable pull shackle. The only change required here is to move the fixed pivot away from the front end of the frame and spring, to the rear point of attachment between the front spring and the frame, and to move the shackled pivot to the forward end of the front spring and frame, merely reversing the ordinary practice. Here the centers C' of arc C and D' of arc D are close together and the circular paths C and D traversed respectively by the axle with its steering knuckle arm, and by the front end of the steering link, are practically coincident and the parts move practically together instead of pulling against one another. By making the shackle of a strong U-form any tendency to side sway can be easily prevented. There is no trouble in this day of Hotchkiss drives in making the spring strong enough, and the fact that with this construction the spring pushes the front axle instead of pulling it, makes the mounting of the axle of increased resiliency and, with a well built spring, is a positive advantage because of the added resiliency. There can be no doubt that such suspension can be used successfully, for the form of Fig. 1 is in use every day on Fifth Avenue, New York, in the Daimler buses.

Not the Ideal Arrangement

The arrangement of Figs. 1 and 2, while much better than the present practice, is not all that can be desired, because both the steering arm pivot D' and the spring pivot C' cannot always be brought into direct line with one another transversely of the car so as to get the same radius for each, and because an element so disregarded, namely the bending of the spring itself and the change in length due to the bending, varies to some extent the radial or circular movement in the case of the axle and its knuckle arm, whereas the steering link is, of course, inflexible and of unvarying length and turns on a true arc.

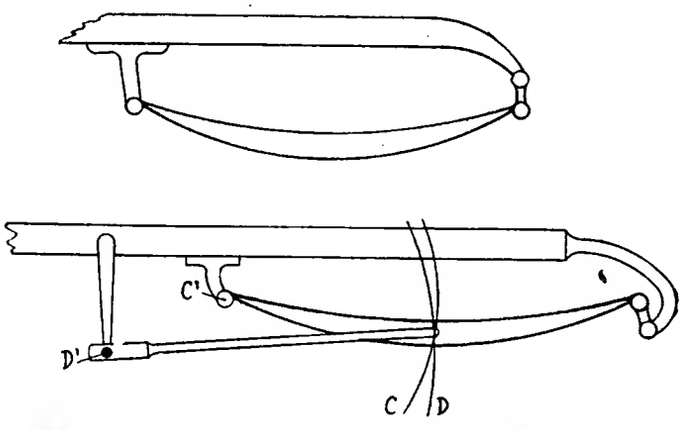
These various details, however, are of minor importance as compared with the one really important consideration, namely that the centers of rotation are both on the same—the rear—side of the front axle, and the natural paths are substantially the same and the conflicts between them and the various defects resulting therefrom are greatly reduced, so much so in fact, that it is apparent beyond question that the substitution of the Daimler front spring suspension for the present standard type would be a big step in advance in motor car design and one very much worth while.

Minor Variations Easily Overcome

Such minor variations as do occur between the paths of the steering link front end and the steering knuckle arm with the Daimler type may be completely done away with.

Whenever the springs are used as the sole means of securing the front axle to the frame, however, the actual movement of the axle and the path it traverses relative to the frame is quite complicated, involving rotation on a spring pivot or pivots and also changes in length of the spring due to its bending and unbending. It is only by floating the front axle on its springs and making use of radius rods, or of a radius yoke, for controlling its movement that it can be made to move in practically a true arc. When such radius apparatus—a radius yoke is preferable to rods—is pivoted to the frame or to some part rigidly connected to the frame, such as the engine base, with its pivotal support at the same distance back in the frame as the steering arm of the steering gear, the front axle and the forward end of the steering link move in practically identical arcs and there is substantially no discrepancy or conflict between them.

Such a radius yoke construction with the axle floated on semi-elliptic springs is illustrated with push shackles in Fig. 3, and with the preferable pull shackles in Fig. 4. Fig. 5 is



Above—Fig. 1—Push type front spring shackle connection
Below—Fig. 2—The more desirable pull shackle which is easily obtained

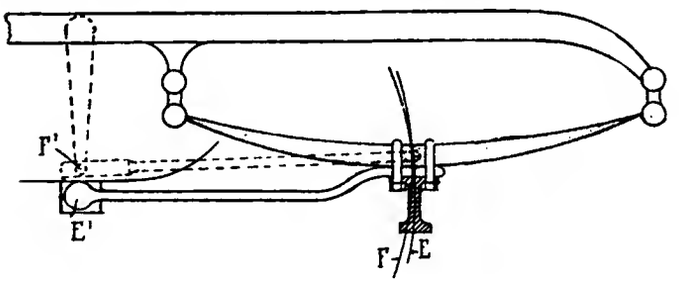
a bottom plan view showing how the radius yoke is secured to the axle. In this form the ordinary semi-elliptic springs are used, the only differences from present standard construction being that the springs and axle are made to float freely by the addition of an extra shackle at the forward end, and then the floating action is controlled by a radius yoke fixed to the axle in any convenient way, having a universal mounting at the rear end in a socket.

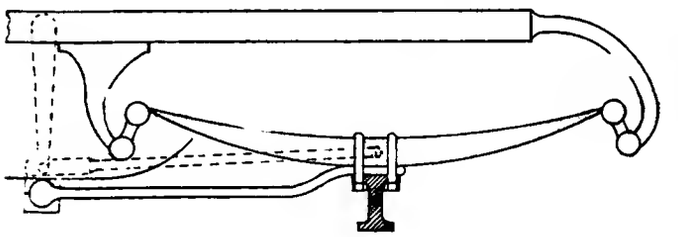
It will be quite apparent how the axle movement and the movement of the steering link front end are substantially identical with this type of construction, the center *E'* from which the axle turns on path *E* being at the same distance back in the frame as the center *F'* from which the steering link front end turns on the practically identical path *F*.

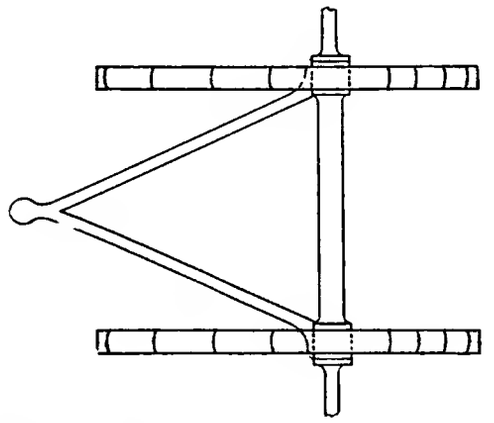
By placing the centers *E'* and *F'* together in this way, every one of the objectionable features of the present standard type of front spring construction is done away with, there is no wabble of the front wheels accompanying the spring action, and the steering wheel is not moved no matter how violently the front wheels and axle may play up and down. Their movement never gets to the steering wheel and is not felt there in the slightest degree.

Appearance Little Changed

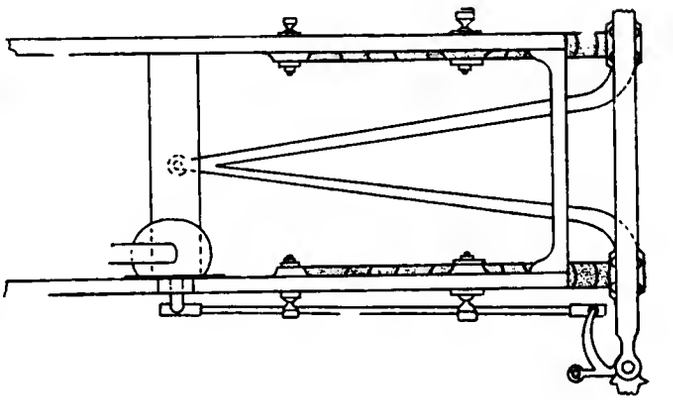
The departure in appearance from present standard construction is inconsiderable. The present projecting horns are retained and the ordinary observer would never note the addition of the extra front shackle and the torsion yoke beneath the machine.

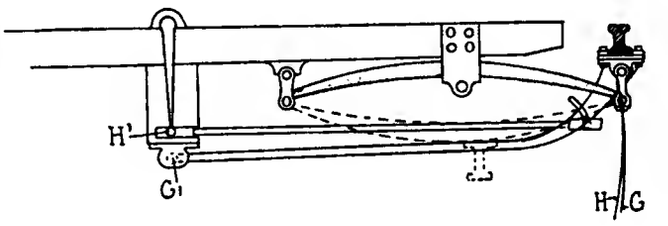


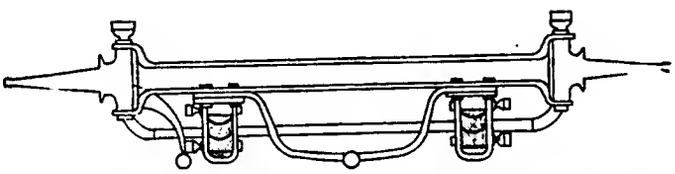




Upper—Fig. 3—Radius yoke construction with the axis floated on semi-elliptic springs, using push shackles. Middle—Fig. 4—With the more satisfactory pull shackles. Lower—Fig. 5—Bottom plan view, showing how the radius yoke is fastened to the axle







Upper—Fig. 6. Middle—Fig. 7. Lower—Fig. 8—These illustrations show a form of front spring suspension using full length semi-elliptic cantilever springs, the front axle being floated from their forward ends and its movement being controlled by a radius yoke

This construction may be properly criticized, however, in at least one particular. It does not afford an opportunity for reducing the height of the car body and frame. In this respect it is like the ordinary standard construction now in use which, as is well known, determines the frame and body height and prevents its considerable reduction.

Figs. 6, 7 and 8 show a form of front end suspension in which full length semi-elliptic cantilever springs are used, the front axle being floated from their forward ends by pull shackles and a radius yoke used to control the movement of the axle.

The front axle, with this type of mounting, pivots on the center *G'* where the radius yoke is mounted with a universal joint. This may be on the engine base or on a cross member of the frame, as is most convenient. It may readily be placed the same distance back on the chassis as the steering connection *H'*, and when this is done the circles *G* and *H* are practically identical and there is no interference whatever between steering action and spring play. The bending of the spring and its change in length, due to bending, does not affect the axle movement in any way, for the axle is floated from the spring on the pull shackles. It will be readily apparent how, with this construction, the wheelbase may be increased without lengthening the frame by merely moving the spring attaching connections forward, and how the body may be lowered as much as is desired by proportioning the spring connection and links to get almost any desired height. Straight line drive is readily possible, if wanted. The dotted lines in Fig. 7 show, for comparison, the added height which results from the use of the present conventional type of construction.

On the debit side of this structure must be placed the fact

that it adds a few pounds in weight and may cost a trifle more than the present type of construction. Where these things are determining, as in the cheaper cars, the Daimler construction may be made use of as it involves no necessary increase of weight or cost, the position of fixed pivot and shackled pivot merely being reversed from those now in use. In appearance its aspect may be considered unpleasing because it is different from that to which the public is accustomed, but the public readily gets used to things which are different if they are really better.

On the credit side of the construction shown in Figs. 6, 7 and 8, however, there are so many items of real importance that any small disadvantages are dwarfed into insignificance. Among such advantageous features of this construction are the following:

The construction is mechanically right; it gives the spring cushioning effect which a spring suspension must give, it prevents side sway and the axle movement is in perfect accord with the movement of the steering connections with no interference whatever between them. The wear on front tires caused by pivotal movement is done away with, the wear on the steering gear is minimized and, even with a reversible steering gear, the front axle may move freely up and down without turning the steering wheel at all. The wheelbase may be lengthened at will without extending the frame. The advantages of an underslung frame are obtained without the disadvantages which go with such construction. The body height may be decreased without cutting down the road clearance. Straight line drive is made possible, and a simple, straight, strong form of front axle may be used. Cars equipped with this type of front spring suspension cannot fail to make a strong appeal to the discriminating car owner-driver, because the floating axle and torsion rod give great driving ease and comfort, the most violent front wheel and axle movement taking place freely without being transmitted to the steering wheel at all.

It is safe to say that the ultimate car of the future, to which we all are looking forward, while it may not have any of the types of front spring suspension which have been referred to in this series, it will, at least, *not* have the obvious defect of a front axle pivoted to turn from a pivot in front of it and a steering link pivoted away behind it.

French Army School Trains Drivers

(*Continued from page* 227)

mechanics must be capable of handling such widely contrasting designs as a Ford and a Lanchester; a 1902 superimposed valve Metallurgique and a 1915 Packard; a Bugatti with cylinders like a liqueur glass, and a Mercedes with a capacity of a couple of liters in each cylinder.

Little Specialization Possible

All this repair organization has had to be got together hurriedly since the war, a task the difficulty of which will be understood by any person who has had to deal with automobile repairs on a big scale. Although the number of vehicles permanently in hand runs into hundreds, it is not possible to specialize to any great extent. Every car received for repair is examined, tested if necessary, and then reported on. It is then turned over to a group of three mechanics, who carry out all the repairs indicated on the docket, but are instructed to report if, in their opinion, any defective part has been overlooked. Attempts to specialize by forming engine, gearbox and rear axle teams have been found to be impracticable owing to the varying nature of the work and the variety of cars handled. Fluctuations are so great that some of the teams would be overworked while others had nothing to do. Making a single team responsible for the entire car limits and defines responsibility, rendering it possible for the officers to come back on the culprit if complaints are received after a car has returned to service. Naturally there are special sections for the repair of radiators, for acetylene welding, and for the various kinds of machine work. Generally, owing to the necessity of waiting for spares or parts being machined, each group of mechanics will have three or four machines in hand at once.

Defects Revealed in Repair Shop

It is interesting to note that very few of the officers are men who have graduated in the automobile factories. For various reasons which it is not desirable to amplify here, the professional automobile engineers have been returned to their respective factories and are doing good work there. The repair depot engineer officers are skilled men drawn from various branches of mechanical engineering and come to the automobile without any prejudices or pre-conceived ideas in favor of this or that make.

It is not an easy matter to tabularize the defects revealed in this repair work. Every vehicle is found to have some weak point when put on war service or placed in the hands of an unsympathetic driver; but what may be the weak point of one is probably the strong point of another car. Speaking generally, universal joints give a considerable amount of trouble; there is also a lot of repair work on gearsets; owing to unskilled handling motors still call for much attention, because of defective lubrication systems or inability of the drivers to give the necessary attention. Rear axles are not a very prolific source of trouble. Even here, however, there are considerable variations. As an instance, Renault and one other high-class make were performing similar service of an arduous nature. The Renault, which is a one-piece forging axle housing developed no trouble in this organ, while the other make, with a built-up axle housing had against it several fractured housings.

The officers in charge of the repair work are not on the whole partisans of forced feed lubrication for war conditions. Their experience is that foreign matter is not kept out of the oil, and under a pressure system this matter is forced into the bearings with destructive effects. The system which, in their opinion, kept the motor in the best condition is the circulating constant-level splash adopted by Panhard-Levassor. Under this system the oil is fed to the front trough and overflows to those behind it, the supply of oil being proportionate to the throttle opening.

Old Touring Cars Useless

During the visit to this formation it was realized that there is not much practical patriotism in the donation of old touring cars to the army for Red Cross Service. On several occasions well-intentioned English people have gathered together all kinds of touring cars which, after being stripped of their original bodies, have received an ambulance body and been sent for service with the French troops. Many of these gifts were old chassis, only fit, with considerable coddling, for service at home. Among them were noted chain-driven Napiers, which must have been built not later than 1902. The inevitable result was that such vehicles were wrecks by the time they had completed the journey from the coast to the front, and had to be returned to a repair depot, where the officers hesitated to waste good labor on them. A few of the numerous cars of this sort are shown on page 226.

The FORVM

USE OF AUTOMOBILE POWER PLANTS FOR RAILWAY COACHES IS PRACTICABLE WHEN LOADS ARE LIGHT—INACCURACY PERMISSIBLE IN CRANKSHAFTS

Railway Trucks Coming

By H. C. Tully

WHILE the railroads have been spending their time and their money on motive power that will drag all the tons the couplers can hold, the automobile world has developed machines that the railroads can now use. Hundreds of runs are made with so small a load that they should be handled by smaller motive power such as would be contained in a railway motor truck.

Any automobile engineer can turn out a power truck for a passenger coach that will be the same success as an automobile design they may work out for a season's hundred thousand cars production. There is no doubt but what such a truck will do the work; as it need not have a single experimental part.

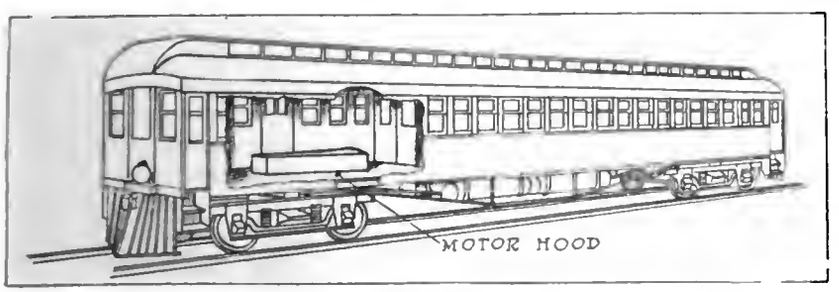
The car body can be made structurally strong enough to satisfy any master car builder by leaving in the body bolster and replacing the cut center sills by a steel diaphragm that will let the car floor clear the engine on any curve as shown by the line drawing herewith.

The control of the mechanism on the truck from either end of the car body can be electrical (absolute and not experimental) by the use of Westinghouse electro-pneumatic brake valves and the Cutler-Hammer magnetic gear shift—the magnets wound for the 32-volt "axle-light" car circuit. There is 90 lb. of air pressure on a rail car, which could be used to release the clutch. The designer is allowed free rein to obtain strength, as a few pounds more does not matter with a railway car.

Chance for Parts Makers

The possible railroad market for an automobile parts maker's product is much larger than a sales manager may think; there are only 277 railway motor cars now in service on 121 different steam roads in America, and there are 997 roads altogether. As additional customers for such cars there are also 1335 street railroads.

While the railway motor truck is a way for steam roads to handle a lot of business with two or three trainmen instead of five, as is now the case, the electric lines need in their rolling stock such trucks, too, for emergency use. The gas engine can drive a car through the gearbox anywhere any other motive power can, and when central station or transmission lines are out the motor truck will be on the job.



Illustrating application of automobile power plant to railway car for runs with light load

Permissible Crankshaft Inaccuracy

By A. Ludlow Clayden

THE crankshaft of a four-cylinder engine, theoretically has all four crankpins in the same plane, and a six-cylinder crankshaft has the pins so set that each lies in a plane making 120 deg. with the plane in which the next pin lies. Actually, of course, there is always some inaccuracy in manufacture, both as to angular relationship between the crankpins and as to the throw of the cranks. An engine with a nominal 5-in. stroke, for example, may have a minutely different stroke in each cylinder, varying from 5 in. plus some fraction to 5 in. minus a corresponding amount. There is not, however much difficulty in getting the crank throws accurate within very small limits, nor is it hard to machine a four-cylinder crank so that the four crankpins are all in the same plane within a very small amount indeed. The six-cylinder crank is not so easy though, because the cranks are twisted to the required 120 deg. while hot. Naturally this is not a very accurate process, so there are two alternatives in machining. One is to machine for accuracy without regard for the fact that some pins will be thus displaced a little in their relationship to the webs, and the other is to machine each pin so that it is, individually, true to its adjacent webs even if this makes the angular relationship between one pin and another somewhat inaccurate.

The point has been raised by a correspondent of THE AUTOMOBILE who is building six-cylinder engines and desires to know just how much inaccuracy in angular relationship ought to be permitted. To make a perfectly accurate crank calls for the removal and waste of a good deal of stock. Naturally if this can be reduced by allowing an angular variation it makes a better production scheme. So the question resolves itself into a decision as to how much variation can be permitted without affecting the operation of the engine.

Of course, *any* variation has a detrimental effect upon the balance of the reciprocating parts, but another point which needs consideration is the effect upon the timing. Near the dead point 3 or 4 deg. of crankshaft movement makes very little difference to the position of the piston, but at a point nearer midway of the stroke, such as the ignition point at maximum advance, 4 deg. may make quite a substantial difference. The opinions of manufacturers of six-cylinder engines would be very interesting.

The History of the Pneumatic Tire—14

Cemented Tire Cheap and Widely Used—The Tillinghast Basic Patent on Process for Making Single-Tube Type—Palmer's Thread Construction—Measuring Rebound of Tires

The History of the American Automobile Industry—41

By David Beecroft

AS mentioned last week, the cemented tire was cheapest and most widely used in 1892 and 1893. This type of tire had its casing split for a short distance on the base to permit inserting a tube having closed ends.

Clincher Type Popular

The G. & J. clincher type came next in favor and was recognized as a superior article but limited to the better class of goods. The Dunlop wired edge never attained a very high degree of favor in spite of its admittedly best qualities because of the methods used or not used in its introduction. This experience should be a hint to American makers who have goods to introduce in foreign countries.

The Tillinghast Patent

While the double-tube tire was striking the many attempts to secure a place in favor, the hose pipe, or single-tube tire, continued on its almost unnoticed way. A patent issued to Pardon W. Tillinghast, covering a process of making the single-tube tire, was found to be basic and eventually practically dominated the tire industry. The later years of the century, when the bicycle business slumped and makers turned their attention to the motor vehicle, found the single-tube tire on a large majority of the bicycles, with a sprinkling of cemented double tubes and G. & J.'s, with an occasional Dunlop.

Palmer's Thread Construction

While the vigorous development of tire designs was going on in the early '90's, students of the subject were busy investigating constructions. The Palmer thread tire has already been mentioned, in which the threads were placed parallel to each other and with one layer over the other, so that the respective threads of one layer crossed those of the other. The Lozier company brought out a tire in which the threads of the fabric ran directly across the circumferential length of the tire. To hold these threads together, lengthwise threads were used along each side of the casing, which was objectionable because it stiffened the casing where it should be free to bend and thus caused the tire to break more quickly, besides interfering with its smooth action. This construction was later modified by leaving out most of the side threads and using only enough longitudinal threads along the quarters to prevent the threads from being separated so far as to tear the rubber. The action of this tire when it encountered a pebble was to swallow it perfectly and without increasing the longitudinal strain on any other portion of the tread than that which was directly in contact with the ground or obstacle. This theory seemed to be correct, but unless the separation of the threads was limited by some means, the rubber would be stretched, easily punctured, and finally, badly torn.

Other Thread Types

Recognizing this fact, Charles E. Duryea and some others introduced fabrics which were meshed like fine fish net and which were stretched around the short diameter of the tire so that their threads were placed almost directly across the circumferential length and quite close together. They were therefore free to stretch in a circumferential direction up to the limit imposed by the mesh, which limit was presumed to be within the ability of the rubber, and because of the mesh a puncture could not extend by tearing, because the fabric strength prevented this. Several patents were issued to Duryea, showing this construction, but, because of the added expense and the cost of getting them on the market, the rubber company to which they were assigned failed to push them.

It has already been mentioned that bicycle racing men quickly found a difference between tires and tire fabrics in the matter of ease and speed, but were not clear as to what was the cause of this difference. To remedy this lack, Duryea, in 1892, constructed a very simple device for making a card of the number of bounces a tire would make when its wheel was dropped from a given height. A similar machine was made by the Victor Co. in 1893, and two cards from it were published in 1894, while in June of the same year a lengthy article by Duryea, with sixteen cards, appeared in *Bearings*. The Duryea machine was quite simple, embodying the use of a long axle hinged to the wall, so that the wheel could be lifted easily while a pencil and card served to register each bound. This device will be described in greater detail in the next installment of this series.

The Rostrum

Jack Bracket As Standard Axle Fitting

EDITOR THE AUTOMOBILE:—It would give me great pleasure if you would grant me a space in THE AUTOMOBILE in which to express my views on the Shortcomings of the Conventional Lifting Jack. As a practical man I have had the experience with most every make of car, and I find that the majority of American-made cars, or rather the designers of the rear axles in American-made cars, have overlooked this minor but very important detail of providing a place on the rear axle for a jack.

Some Axles Present No Problem

Where some of our manufacturers have been successful in overcoming this much needed feature, not due to providing a place for the jack but due to the clean-cut or simple construction of the rear axle, one would be able to place a jack anywhere between the differential housing and the brake drum, whereas, on the other hand, a rear axle constructed with truss rods underneath and no provisions for a jack makes it next to impossible to place same under this type of rear axle.

A Practical Suggestion

In THE AUTOMOBILE for July 27 the sketch, Fig. 1, I must say, is a very neat and practical idea and could be carried out very nicely by many rear axle manufacturers if they so desired, and in that case it would be possible to place a jack under such an extension of that type with ease for a tire change, providing the tire cross section does not exceed 3½ to 4 in., as one must bear in mind that when a tire is flat it is considerably wider. But on the other hand, if a car is equipped with a tire having a cross section of from 5 to 6 in. and a jack base of approximately 5 in., the placing of the jack under the place provided in Fig. 1 would be impossible, and in this case last mentioned it would be necessary to have the special bracket as in Fig. 1 extended toward the differential housing at least 3 in. to allow a change of this kind to be made. Therefore, in adding a bracket to the rear axle it would be necessary to give it due consideration to allow for those cars where the rear wheels are equipped with oversized tires.

As I have experienced just such difficulties on both foreign and American-made cars and would greatly appreciate for all concerned if an addition of such an absolute necessity could be made a standard equipment on at least all American cars.

As for the sketch, Fig. 2, I fear one would meet with many complications, as it would necessitate every automobile owner to carry a different type of jack head to suit the different kinds of rear axle construction in his car, and many other difficulties would be experienced which, I am sure, need no explanation. Also it would not be a standard equipment. This probably is the main reason for this particular type having not been adopted either in this country or Europe.

Orchard Lake, Mich. C. H. BUCKMAN.

Circuits of Remy System on Madison

Editor THE AUTOMOBILE:—Kindly publish a circuit diagram of the Remy electric system used on the Madison.

Brooklyn, N. Y. J. N.

—Circuit diagram of the Remy electric system used on the Madison cars appears in Fig. 1.

Adjusting Model H Schebler Carbureter

Editor THE AUTOMOBILE:—Kindly publish an explanation of the method of putting model H, latest type, Schebler cyclecar carbureter in full adjustment for maximum fuel economy under normal running conditions and for speed work. How should this be altered for a change in atmospheric or weather conditions? What is the small butterfly valve in the lower end of the air intake used for?

2—On page 466 of THE AUTOMOBILE for Feb. 19, 1914, a special cyclecar drive belt is described and the maker, Duckwell Co., given. Kindly give me the address of this firm or any other making a similar belt.

Glen Ridge, N. J. P. S. W.

—The only difference between the cyclecar Schebler carbureter H and the regular type is in the air valve, as the cyclecar type has the device for locking the air valve when cranking the car. The method of adjusting is as follows: Referring to Fig. 2 for low speed adjustment see that the letter air valve *A* seats lightly but firmly, then turn the knurled button *I* to the right until the needle point *E* sets in the spraying nozzle, or in other words, as far as it will

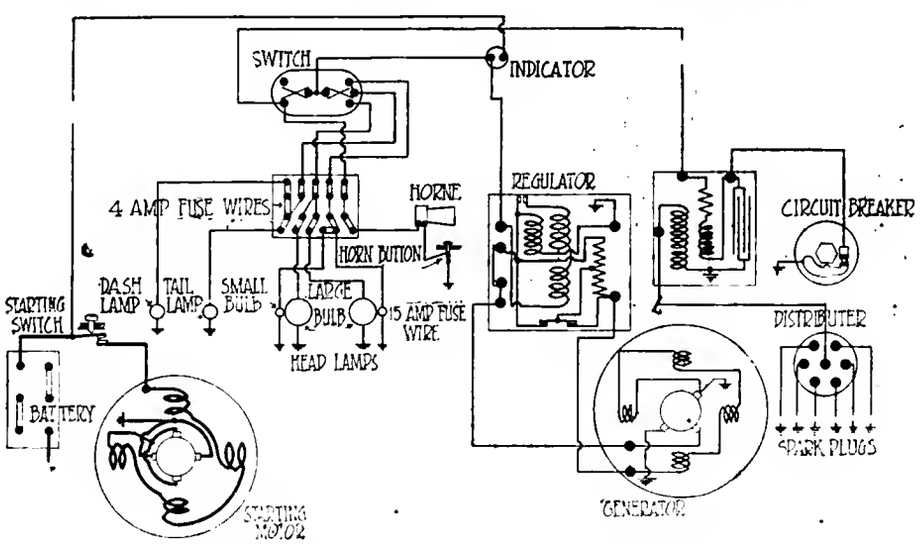


Fig. 1—Circuit diagram of Remy electric system on the Madison car

go without jamming. Then turn the button *I* to the left about two turns and open low speed adjusting screw *L* about three turns. Then open the throttle about half way and start the motor. After the motor starts close the throttle and turn the needle valve adjusting screw *I* to the right or left until the motor runs smoothly without missing. If with this low speed adjustment the motor runs too fast turn the low speed adjusting screw *L* to the right.

The carbureter is now ready for the high speed adjustment and the throttle and spark should be opened wide. The adjustment is now made by the pointer *Z* which as it moves from 1 toward 3 on the dial lowers the cam, thereby raising the needle and increasing the gasoline supply. Moving the indicator from 3 toward 1 raises the cam and cuts down the gasoline. When the indicator is at the right point the engine will run without missing or backfiring. If when the lever *Z* is turned to 3 the mixture is still too lean, causing the motor to backfire, the tension on the air valve should be increased by turning the adjusting screw 12 to the left.

For starting a wire should be attached to the shaft 12 which pulls out and locks the air valve *A* by compressing the spring behind the air valve. The shutter *C* in the air bend should also be connected with a wire thus allowing both primary and high speed air to be choked at the same time. This insures a rich mixture for starting.

2—The company that you refer to is the Duckwell Belting & Hose Co., 201 North West Street, Indianapolis, Ind.

Levett Pistons Made in New York

Editor THE AUTOMOBILE:—Who builds the Miller car and who makes the Levett pistons?

2—Will a six-cylinder motor firing 1, 2, 3, 6, 5, 4 develop as much power at 1500 r.p.m. as one firing in the conventional order?

West Milford, W. Va. B. BROS.

—THE AUTOMOBILE has no record of the Miller car. The Levett pistons are made by the Walker M. Levett Co., 417 East Twenty-third Street, New York City.

2—No. The unbalanced forces in a motor firing in this way would greatly reduce the power output.

Wants Higher Power and Speed

Editor THE AUTOMOBILE:—Can you advise me where I can secure a second-hand 300 cu. in., sixteen valve, high-speed engine?

2—Would it be advisable to install longer connecting-rods to raise the compression on a 4½ in. by 5 in. engine, after installing alloy pistons and rods, also larger camshaft, and manifold and carbureter, would increasing the compression increase the power and speed, if so to what extent, and how many pounds compression would you advise?

3—Would there be any disadvantage in raising compression; would the pick up be any better?

4—What type rear axles are used in racing cars, floating, semi-floating or three-quarter floating, and why is the type used in preference to others?

5—What kind of steel is used to make the live axles in racing cars, and where can it be secured?

6—How do you line up a semi-floating rear axle so as to obtain the least friction?

Gaffney, S. C. W. R. T.

—THE AUTOMOBILE has no record of any of these for sale.

2—This would depend altogether on the design of the engine. On some it would be impossible due to the shape of the cylinder top and the lack of clearance between the rod and the bottom of the cylinder. It is impossible to state the number of pounds per inch increase in compression due to lengthening the rod unless you advise the exact volume of the compression space. Knowing this it is quite easy to calculate mathematically the compression increase. The formula for this

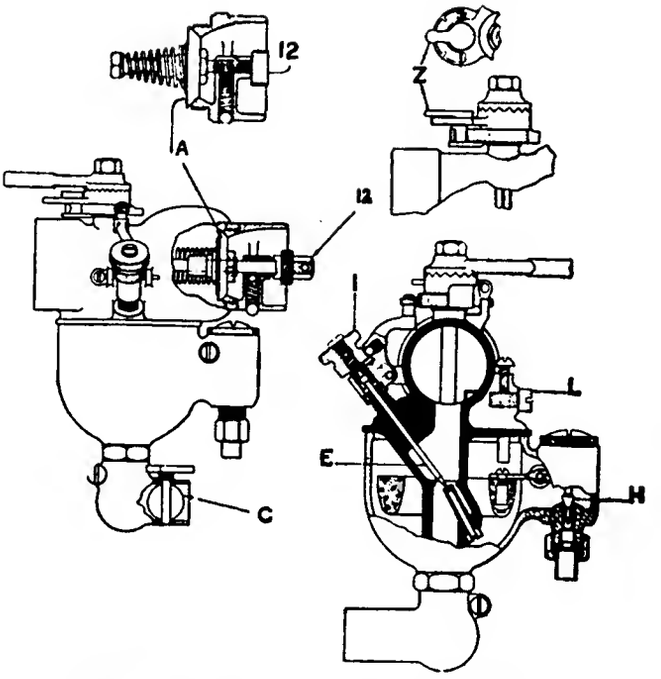

Fig. 2—Schebler model H carbureter, showing adjustments

is $P V^{1.4} = P_1 V_1^{1.4}$. Where P is the compression at present, V is the present volume of the combustion chamber, P_1 the compression at the volume V_1.

3—For high speed work there would be an advantage in raising the compression. Whether or not the performance would be better depends altogether on the design of the motor and what you are getting now.

4—A majority of the racing cars use floating axles.

5—Chrome nickel steel is used for the axles in racing cars. At the present time it is difficult to state where one or two shafts alone could be secured as most of the larger companies are tied up on their regular production orders. You should be able to secure shafts, however, from almost any of the axle companies.

6—The alignment is simply a matter of bearing location and this is taken care of in manufacturing.

Heavier Wedges Will Secure Rims

Editor THE AUTOMOBILE:—Will you kindly advise me if there is any straight side rim that I can put on wheels now equipped with Baker detachable rims that are heavy enough so that they will hold their shape and not squeak? I have always had this trouble with these rims and am of the opinion that they are too lightly built. Any suggestions you might make would be very much appreciated.

I do not want to go to the expense of taking the wheels to New York and having them rebuilt and refitted for another make of rim if there is a detachable rim such as I want that can be substituted without these changes.

Amityville, N. Y. H. H. T.

—It would probably be impossible to fit rims of another make without rebuilding the wheels. At all events, it would be a risky experiment. You can, however, remove the looseness from your present rims by installing wedges that are larger and thicker than the original ones. If the rim and the felloe band are in good condition this will bring the rims tight on the wheels.

Standard Automobile Gage Is 56 In.

Editor THE AUTOMOBILE:—What is the standard gage of an automobile?

West Kortright, N. Y. F. H. O.

—The standard gage of an automobile is 56 in.

ACCESSORIES

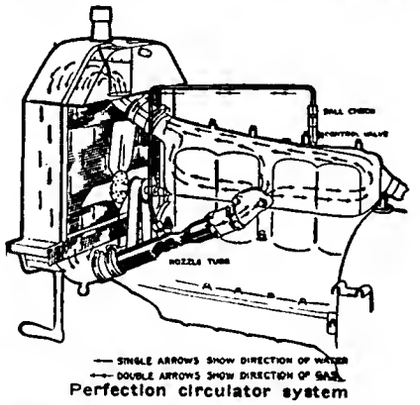
Evapco Auxiliary Air Valve

THE Evapco device is designed to reduce fuel consumption and carbon in the engine and at the same time to give better and more complete combustion with consequent increased power by supplying additional air to the intake manifold. It consists of a metal casing inclosing an automatic valve and screwed into the intake manifold. At low speeds the valve is held closed so that the normal mixture is supplied to the engine which would not operate well when turning over slowly if the mixture were too thin. As the speed increases the valve opens and admits air in proportion to the speed. No adjustment is required and the valve fits any make of car. It is installed by tapping a ⅜-in. hole in the manifold and screwing in the valve. The device sells for $5, prepaid. —Evapco Mfg. Co., 427 Grand River Avenue, Detroit, Mich.

Evapco auxiliary air valve, which automatically feeds additional air to the intake manifold in proportion to the engine speed

Hull Self-Service Pump

This is a curb pump designed to handle the sale of gasoline automatically without any attention whatever on the part of the garageman except to keep it filled and to change the vending mechanism as the price of gasoline varies. The advantage of this pump is that it enables the motorist to purchase 25 cents, 50 cents or $1 worth of gasoline by simply dropping in coins to this amount. The mechanism is so devised that when the tank is empty the coin slots are automatically closed.—Hull Pump & Tank Co., Owensboro, Ky.



Perfection circulator system

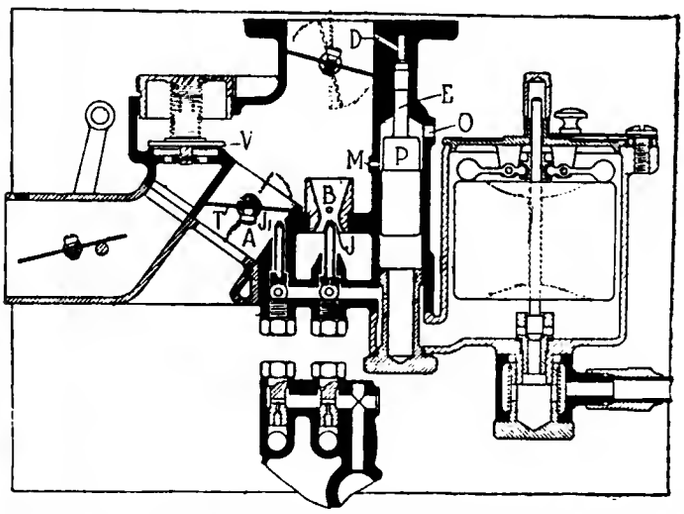
Perfection Water Circulator

The Perfection circulator is an air-operated ejector, designed to utilize a small portion of the exhaust gas from the engine to operate a device which will give uniform temperature to the motor regardless of the conditions under which it is operated. As will be seen by the illustration, the attachment consists of a specially designed nozzle tube connected with the exhaust manifold through piping which is carried over the motor. The gas is carried into the lower connection between the radiator and the engine. The water at this point is forced forward by the exhaust gas moving in the direction imparted by the jet, which is toward the engine. The water will be forced forward and through the cylinder jackets with a velocity which corresponds to the amount of exhaust gas pressure, and consequently the amount of engine labor. It is claimed that, with this device installed on a motor, in winter or in cold districts the motor can be maintained at the same temperature of high efficiency as in summer by simply removing the fan belt, any tendency to overheat or boil being immediately offset by the increased rate of circulation incident to the generation of heat in the cylinder. The equipment as illustrated sells for $7.50.—Motor Cooling System Co., Munsey Building, Baltimore, Md.

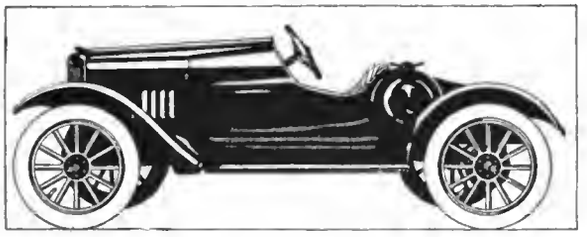
Hull self-service gasoline curb pump

Ball & Ball Carbureter

This is a two-stage carbureter, hot air being used in the primary stage of vaporization and cold air in the secondary stage. Referring to the sectional illustration, at the left there is a hot-air passage with a choke valve; the primary venturi appears at *B; J* is its gasoline jet, and *V* is a spring-loaded idling valve in a fixed air opening. These parts constitute the primary system. In the secondary system *A* is a cold air passage, *T* a butterfly valve and *J* a gasoline jet discharging into the cold air passage. This system is brought into operation by opening the butterfly *T*. A connection between the butterfly *T*, and the throttle, not shown, throws the butterfly wide open when the throttle is not quite wide open; at all other times the butterfly is held closed by a spring. The cylindrical chamber at the right of the mixing chamber has an extension *E* of reduced diameter connecting it with the intake manifold through a passage *D*. A restricted opening connects the float chamber with the cylindrical chamber so that the gasoline level is the same in both. A loosely-fitting plunger *P* in the cylindrical chamber has an upward extension into the small part of the chamber. *O* is a small air opening and *M* is a passage from the cylindrical chamber to the mixing chamber. Air constantly passes through this when the carbureter is in operation. In the working of the carbureter, when the throttle is closed,



Ball & Ball two-stage carbureter, using hot air in primary stage of vaporization and cold air in second



Remo racing-type body for Ford cars

suction on piston *E* causes plunger *P* to rise, closing the passage *D;* the space below the plunger is filled with gasoline. Opening the throttle breaks the partial vacuum and releases the plunger, which falls and forces the gasoline under it to rise and flow through passage *M* into the mixing chamber, forming a rich mixture for a quick pick-up. Under ordinary running conditions only the first or primary system operates; when the throttle is fully opened and maximum power is required the secondary system, with its extra fuel jet, is brought into play.—Penberthy Injector Co., Detroit, Mich.

Remo Ford Racing Bodies

Four styles of bodies are made for Ford cars, and in addition radiator, bucket seats and tanks are sold. The leader is the Model S, which is an attractive design patterned after modern racing cars. It has a high rounded radiator, sloping hood and cowl carried back to inclose the bucket seats. Tank and tires are carried at the rear. Special curved fenders, splash guard and extra long running board, linoleum covered and metal bound, are furnished. The Model C is a three-passenger clover-leaf, with one-piece windshield and fenders, like Model S. The Model R is an extremely light racing design, consisting of bucket seats, gasoline and oil tank, and framework for mounting these units. The Model T is a more elaborate design, with V-radiator, sloping hood and cowl, bucket seats, two tanks, fenders and top.—Auto Remodeling Co., 1501 Michigan Avenue, Chicago, Ill.

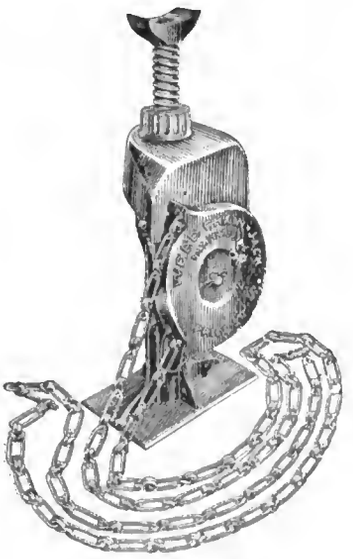
Fold-Up Door for Garages

This door folds up overhead and overcomes the inconveniences of swinging doors in garages where space is limited. It operates with chain and hoist, and can be raised by a child. Choice of wood or metal is allowed. A small hinged door in the panel of the lower section permits of passage without opening the large door. The upper section is built with wire glass panels.—St. Louis Fire Door Co., St. Louis, Mo.

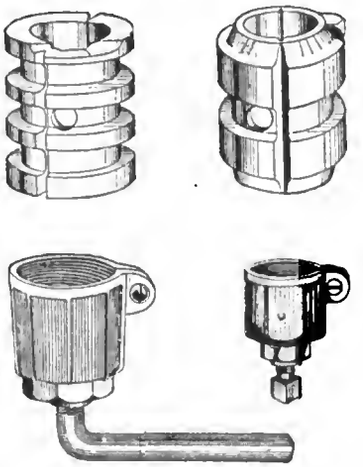
Weed Jack and Tire Lock

The jack is raised and lowered by operating an endless chain. Pulling the chain rotates a sprocket which drives a gear which raises or lowers the lifting member. The chain is non-kinkable and

American tire-lock chain to prevent theft of spares



Weed jack, which is raised and lowered by operating an endless chain driving a gear through a sprocket



C. & E. specialties for Fords. Upper—Camshaft bearings. Lower—Wheel pullers

is easy on the hands, it is said. The particular advantage is that the car may be raised or lowered without crawling under the car or even bending the back; it gives maximum convenience. The 8- and 10-in. sizes are provided with an auxiliary step which may be swung into place, adding 2 in. to the height. The gears are machine-cut, and thrust roller bearings are used. Specifications are:

Size. (Lowered)	Rise, Inches	Capacity, Tons	Price
8	4½	1	$5
10	5⅝	1	5
12	7	1	5
12 truck	7½	5	10

Chains for locking tires are made of flat links which give a strap-like action, permitting them to be drawn closely around the shoes and running board or through the wheel and spring or frame. They are readily attached, and when not in use take up small space in the tool box. They are furnished with wrought-steel japanned cast padlock, Yale & Towne cast bronze padlock or a keyless lock. Prices, per dozen. Galvanized chain, 36 in., with japanned lock, $7.80; Yale lock, $22.60; keyless lock, $22.60; without lock, $4.60. Bright chain, 36 in., with japanned lock, $9; Yale lock, $23.80; keyless lock, $23.80; without lock, $5.80. Bright chain, 36 in., covered with oil-tanned leather, japanned lock, $12.70; Yale lock, $27.50; keyless lock, $27.50. Forty-two- and forty-eight-inch sizes at additional prices.—American Chain Co., Bridgeport, Conn.

C. & E. Specialties for Fords

These muffler cut-out sets for Fords consist of a cut-out valve which clamps over the exhaust pipe, pedal, spring and pulley. They have 1⅜- and 2-in openings, the prices ranging from $460 to $560 per thousand.

A wheel puller for Ford cars consists of a threaded cap with a screw in the center. The cap is split at one side so that it may be clamped tightly about the hub, and then a screw is turned. The price with set screw is $300 per thousand, and with lever instead of set screw, $340. Camshaft bearings for Ford cars are made from high-grade smooth gray iron; price, $100 per thousand.—C. & E. Mfg. Co., Marshalltown, Iowa.

Fold-up door for garages, which is out of the way when open

Our Foreign Trade

GOVERNMENT figures on automobile exports for the fiscal year ending June 30, 1916, suggests the necessity of our manufacturers watching very closely the movement of foreign trade. These figures bring three sections of the world into particular prominence—Australia, South America and the West Indies. The increase in exports to these three parts of the world has been so great that it is imperative that we give increased attention to the problems of exports. We have not a good reputation in any one of the three countries in so far as our business methods are concerned. We have well-nigh a world-wide reputation for being deplorably poor exporters, which is particularly true when doing business with countries using other than the English language.

Our business in South America and the West Indies is attaining that stature that demands shrewd handling. The figures show that we have made heavy gains. With South America our business has increased more than sixfold in a year. War conditions have aided us very materially, and we must be correct in placing the credit for the growth. With us it is essential to be fortifying ourselves to-day to hold the business to-morrow. If we get along without a well-organized foreign department to-day, when we have no competition in South America and Australia, that is no proof that we can hold our own to-morrow when up against the keenest competition of Europe in these fields. We welcome these great increases in foreign trade, but Providence only helps those who helps themselves; and as an industry we are not playing fair to ourselves if we are letting to-day pass without building deeply and permanently for our foreign trade of to-morrow.

South American Trade

NOBODY will question the possibilities of South American business in automobiles, trucks and tractors, as well as varied lines of accessories. The field is there, and although present conditions are not the most propitious the future is sufficiently great to warrant a considerable present investment with little if any immediate returns.

The South American field must be sanely weighed. A few of the major considerations must be carried in mind: The total population is hardly one-half that of U. S. A., and in some of the states, like Brazil, Bolivia and Peru, there is a large percentage of colored population that cannot be counted as an average potential buying factor.

Gasoline a Temporary Factor

At present the price of gasoline is so high as to make many business men refuse to consider buying motor trucks or farm tractors. Gasoline will not always be a serious factor, and it can be dismissed as offering only temporary troubles. If gasoline eventually is too expensive there is no reason why alcohol cannot be used, as nearly all South American countries can produce it in great quantities.

To-day there is the problem of unimproved roads, which can be dismissed as temporary, as in all parts of South America the motor car will bring about improved roads, as it has done in U. S. A.

We must face the question of high ocean freight, and the further fact that as a nation we have few ships, and for our South American trade we have largely to depend on the ships of our business rivals. To-day we are paying higher freight rates from our shores than Europe is. In some cases our rates are nearly three times as high. Should Europe desire, she can, after the war, give preferential shipping rates that will handicap us seriously, and perhaps go far to offset the advantages we have gained by rapid production. Europe is not going to assist us in taking away her trade, and we must look ahead a few years, when the war is over, and see how our shipping facilities will measure up. You cannot do business in South America if your freight rates are twice as high as those from Europe.

One thing that is bound to aid us very materially is the greater investment of U. S. A. capital in those countries. Trade is sure to follow heavy investments. The trade control of England and Germany attest to this. Our capital is going into South America very rapidly within the last two years, and already increased trade is showing itself, and we should rationally prepare to take care of it on as good a business basis as we take care of our domestic trade.

Represents Packard in S. A.

Cardway Will Establish Agencies—Cold Damages Crops in Argentine

DETROIT, MICH., Aug. 5—The Packard Motor Car Co. is sending Fred Cardway to South America for an extended tour to place new agencies. He will leave in September and will visit all the important centers throughout the continent. Mr. Cardway will make his headquarters at Rio de Janeiro, Brazil.

Frosts Injure Argentine Crops

BUENOS AIRES, July 7—Recent reports show that Argentina has been experiencing more cold weather in the last 3 weeks than it has for several years. So great has been the cold in the sugar section around Tucuman in the northern part of the country that there will be a great shortage in the sugar crop of next year. The young sugar cane has been burned by the repeated frosts and many new plantations have been killed by a succession of heavy frosts. Some predict that the crop of 1917-18 will be nearly a complete failure.

No part of Argentina seems to have escaped the severe cold, and although snowfalls are unknown in the country, there was a considerable fall in one section on June 26 and 27. The cold and frosts have necessitated many of the large farmers feeding their cattle which is most unusual in the winter season in Argentina.

The country is suffering from a lack of coal, and in the city of Rosario some of the outlying trolley services have been discontinued due to this cause. Nearly all of the coal comes from U. S. A. and the present shortage is due to lack of ships.

—

Baker Cole Eastern Sales Manager

INDIANAPOLIS, IND., Aug. 7—E. H. Baker has been appointed central eastern sales manager for the Cole Motor Co. Mr. Baker was formerly president of the Cole Motor Co. of Buffalo and is now in charge of the sales in western New York, western Pennsylvania, West Virginia northeastern Ohio, southern Michigan and the Province of Ontario. Wm. L. Colt, president of the Colt-Stratton Co., will have charge of the extreme East and in the South W. P. Dorough will be in charge, with headquarters in Atlanta. J. E. Roberts has been appointed to take care of the western territory.

—

Torbenson Buys Land and Adds

CLEVELAND, OHIO, Aug. 7—Four acres of land have just been purchased here by the Torbenson Gear & Axle Co. of this city. This is in addition to the buildings which are now under construction and which will, by Aug. 15, place 50,000 sq. ft. of manufacturing space at the disposal of this concern. The principal product of the company is the Torbenson drive internal gear rear axle for commercial vehicles. The new factories will be of the monitor type, constructed of brick and steel with metal sashes.

—

Stewart-Warner Expands Plant

CHICAGO, ILL., Aug. 7—Beginning Sept. 1, the manufacture of Warner Auto-Meters will be carried on in the new additions to the Chicago plant of the Stewart-Warner Corp., and the Beloit plant will be devoted exclusively to foundry operations connected with the production of Stewart-Warner products. Plans have been made to double the size of the Beloit plant, the new portion being exclusively a foundry and the present building will be utilized in preparing the castings for machining.

—

Wade Is Buick Purchasing Agent

FLINT, MICH., Aug. 4—Fred A. Wade has been appointed purchasing agent of the Buick Motor Co., succeeding J. T. Wilson, who resigned to enter some other line of business. Until a few months ago Mr. Wade was purchasing agent of the Maxwell Motor Co. Previous to that he was connected with the Studebaker, E-M-F and Ford companies.

—

Leverton Is Briscoe Plant Manager

JACKSON, MICH., Aug. 4—A. C. Leverton, formerly general manager of the Chalmers Co., has been appointed factory manager of the Briscoe Motor Corp. Previous to his Chalmers connection Mr. Leverton was works manager of the Cartercar Company, and before that general superintendent of the Brush Runabout Co.

—

Hastings Goes with Empire

INDIANAPOLIS, IND., Aug. 7—Don T. Hastings, formerly of the Packard and Hupmobile engineering staffs, has joined the Empire Automobile Co. as consulting engineer. Mr. Hastings has been, for some time mechanical engineer of the Herbert Mfg. Co., makers of automobile bodies, fenders and stampings.

—

Maxwell Directors Meet Aug. 15

NEW YORK CITY, Aug. 9—Directors of the Maxwell Motors Corp. will meet Aug. 15 to take action on dividends.

—

Detroit S. A. E. Moves

DETROIT, MICH., Aug. 3—The headquarters of the Detroit section of the Society of Automobile Engineers have been moved to more spacious quarters at 706 Kreage Building.

Simplex in Aircraft Merger

Part of $10,000,000 Co. Made Up of Wright and Martin Interests

NEW YORK CITY, Aug. 8—The Simplex Automobile Co., which for a year has been part of the Wright aircraft organization, is included in the $10,000,000 Wright-Martin aeroplane merger just completed. The Simplex company has for some time been manufacturing aeroplane motors for foreign countries along with a high-priced automobile chassis. The merger will not cause any changes in this policy. The Simplex plant at New Brunswick, N. J., which has been entirely rebuilt, will be used to manufacture the aviation motor which is of the Hispano-Suiza type, and the simplex cars. There are 2200 employees at the New Brunswick plant.

About a year ago the original Wright company which was then owned by Wilbur and Orville Wright, was purchased by a syndicate headed by William B. Thompson, Harry Payne Whitney and T. Frank Manville. The Simplex Automobile Co. was purchased from the Lockhart interests and the capital stock of the Wright company was increased to $5,000,000. E. M. Hagar, formerly president of the Universal Portland Cement Co. of Chicago, a subsidiary of the U. S. Steel Corp., was elected president of the Wright company, in March, 1916.

The principals in the deal are the Wright Co. of New York and the Glen L. Martin Co. of Los Angeles. The new consolidation will be known as the Wright-Martin Aircraft Corp. It will be incorporated under the laws of New York with $5,000,000 7 per cent cumulative convertible preferred stock and 500,000 shares of common stock with no par value. The Martin plant at Los Angeles will continue to be operated and another large factory will be erected in the East near New York. The factory of the Wright company in Dayton, Ohio, will be used as an experimental station.

While the Wright company is probably the largest aircraft patent holder, Glen L. Martin is one of the pioneers of practical aviation in this country. His machines are used largely by the U. S. Government for army work. He will be in charge of the aeroplane department of the new organization and is also, with C. S. Jennison, a vice-president of the new merger. Mr. Hagar is president.

—

Merrithew Is Rayfield District Manager

KANSAS CITY, MO., Aug. 4—H. E. Merrithew has been appointed district manager by the Findeisen & Kropf Co., manufacturer of the Rayfield carbureter.

Rickenbacher Wins at Tacoma

Takes Montamarathon in Maxwell at 89.3 M.P.H.—Milton's Duesenberg Second

WINNERS AT TACOMA RACES

Car	Driver	M.P.H.	Prize
Maxwell	Rickenbacher.	89.3	$4,000
Duesenberg	Milton	88.6	2,500
Crawford	Lewis	88	1,500
Mercedes	De Palma	87	1,000
Maxwell	Henderson	84.5	750
Omar	Toft	84.4	250

TACOMA, WASH., Aug. 5—Eddie Rickenbacher's Maxwell won the 300-mile Montamarathon to-day at an average of 89.3 m.p.h. Ralph de Palma's Mercedes led consistently until his jinx reasserted itself at 175 miles and engine trouble delayed him, giving him fourth money.

Rickenbacher's 100th lap at 96 m.p.h. was the fastest of the day.

Milton received the regular price of $2,000 and an extra $500 and the Golden Potlatch trophy for leading at 100 and 200 miles.

D'Alene, Duesenberg, at sixty-four laps went out with a broken universal. Mossie, Gandy Special, retired at the thirtieth lap with burned bearing. Johnson, Crawford, injured his eye in the first lap with broken goggles but returned at the third lap and stayed until the sixty-ninth lap until a broken valve put him out. Latta, Dodge Special, ran consistently until the ninety-eighth lap, when engine trouble stopped him. Oldfield, Delage, was forced out nine laps from the finish through valve failure.

Lewis drove a thrilling race, running open on the curves and frequently taking the lead until the eighty-first lap, when he went to the pits with his car afire. After a quick tire change, he brought the crowd to its feet by sweeping into third place and making one lap at the rate of 94 m.p.h. Henderson covered 150 laps without a stop. Fast work by the pit men of De Palma and Rickenbacher helped them greatly. The winners' cars were equipped with Goodyear cord tires.

—

77,496 Cars Exported

(*Continued from page* 211)

Perhaps the greatest change in our exports during the past year are those for South America, where the total for the year is 6725 cars as compared with 1264 in the preceding year. Thus the business has increased more than fivefold. Heretofore South America has had one general classification, but now several of the important countries are given separate divisions, Argentine leading by long odds with 4444 cars. Chile comes next with 843, then Venezuela with 524 and Brazil, the largest country in South America, is in fourth position with 283.

There is at present a nip-and-tuck race between the West Indies, including Bermudas and Asia with Oceania as consumers of U. S. A. cars. Oceania has the lead with a total of 5496 as compared with West Indies with 4658. The West Indies business is nearly three times what it was the previous year.

An analysis of the exports to Europe shows that the Allies have during the year been very heavy buyers, taking practically 96 per cent of all cars. The United Kingdom leads with 18,428; France is second, 7768, and Russia third, 5177. Italy took 387 and Denmark 847. Russian business shows a tremendous increase, as previously it was not classified. Exports to England and France show an increase of approximately 50 per cent over the preceding year.

There has been a heavy increase of cars sold into Asia and Oceania during 1916 as compared with 1915, but not nearly so great as to South America, West Indies, Canada and Australia.

—

King Finishes High-Gear Run

DETROIT, MICH., Aug. 5—A King eight has just finished a high gear trip from Providence, R. I., to Detroit and back, the total distance covered being 1800 miles. This performance was made by A. F. Justin, the Providence dealer, and a party of five. The shifting lever was removed and the gears sealed in high, the car being a stock job.

—

32 Entries for Pike's Peak Climb

DENVER, COL., Aug. 5—At five o'clock this afternoon, 7 hr. before the official closing time for entering cars in the first annual Pike's Peak hillclimb next Friday and Saturday, Aug. 11 and 12, there were thirty-two cars entered to compete for the $1,200 Penrose trophy and the $4,800 in cash prizes offered by the Pike's Peak Auto Highway Co. The entries represent twenty makes of cars, all specials, and the list of drivers includes names known throughout the motoring world. The entries follow:

Make (All Specials)	Driver
Cadillac	Brinker
Studebaker	Morgan
Cadillac	Marksheffel
Grant	Jones
Chalmers	Stentz
Chalmers	Walden
Buick	McCoy
Hudson Supersix	Mulford
Wisconsin	Weir
Hudson	Patterson
Duesenberg	Hughes
Peugeot	Hill
Milac	Whalen
Stutz	Duaray
Delage	Oldfield
Maxwell	(Not announced)
Ford	Peterson
Pathfinder	Hughson
Ford	Henry
Packard	Johnson
Ford	Spangler
Peerless	(Not announced)
Ford	Knowles
Giddings	Federman
Stutz	(Not announced)
Buick	(Not announced)
Romano	Lentz
Saxon	Wetmore
Peugeot	Mulford
Duesenberg	Buzane
Duesenberg	Buzane
Hudson	(Not announced)

Packard 12 Breaks Track Record

Aviation Racer Sets New Mark for 300-in. Cars at Indianapolis

INDIANAPOLIS, IND., Aug. 4—The Packard aeroplane twelve exceeded the Speedway record here to-day by ½ sec. This is the first time that a lap of the 2-mile track has been made by a 300-in motor at more than 100 m.p.h. The unofficial time was 1 min. 29.32 sec. The best previous time for a motor under 300 cu. in. was that of Boillot in a Peugeot, 1 min., 30.13 sec. in 1914.

This is the same car that J. G. Vincent, vice-president of engineering of the Packard company, had at New York during April and May this year, with the exception that a new intake header had been added for better performance at high speeds. The car was driven by Rader, who carried a mechanic and 10 gal. of gasoline. This is the first of a series of tests which are to be made by the engineering department to demonstrate the efficiency of the small bore twelve. Mr. Vincent states that the twelve-cylinder engine was of great advantage at Indianapolis as the steady torque made the car hold the turns at the high speed.

Electrical Timing Used

Electrical timing and five stop watches were used, the electrical instrument being the same as that used in timing the classics over the Hoosier track.

Displacing exactly 300 cu. in., this car has already distinguished itself as of exceptional speed. Laps were made with it, during the spring, at speeds of from 100 to 110 m.p.h. on the Sheepshead Bay track. The motor is a V-twelve of 2 21/32 by 4½ in. bore and stroke. The valve diameters are 1 7/16 in. and the lift is 0.34 in., giving a large area for gas flow. A full description of the car appeared in THE AUTOMOBILE for May 4, 1916.

—

Two Peugeots for Harvest Classic

INDIANAPOLIS, IND., Aug. 5—Entries for the Harvest Classic to be held on the local speedway Sept. 9 have started to come in. The two Peugeots driven by John Aitken and Charles Merz are the first two entries. There will be a total of $12,000 in prize money in this race, which will be over a distance of 300 miles. The entry of the two Peugeot cars is made by the Indianapolis Speedway Team Co., and the car which Aitken is to drive is the same as that with which he won the Coney Island cup at New York this spring.

Fisher Body Corp. Formed

Consolidation of Fisher Body Cos. to Issue $5,000,000 7% Preferred

NEW YORK CITY, Aug. 9—The Fisher Body Co., the Fisher Closed Body Co., both of Detroit,, and the Fisher Body Co. of Canada, Ltd., Walkerville, Ont., have been consolidated to form a new organization under the name of the Fisher Body Corp. with a capitalization of $5,000,000 in 7 per cent cumulative $100 par preferred stock and 200,000 shares of no par value.

The additional capital provided by the reorganization will enable the company to greatly expand its facilities and consequently its volume of production. It furnishes bodies to Ford, Buick, Cadillac, Maxwell, Chalmers, Hudson and others, and its business for the current year is estimated at $20,000,000. Last year it amounted to $10,000,000.

Hallgarten & Co. and Eugene Meyer, Jr., & Co., this city, have bought the $5,000,000 preferred and part of the 200,000 shares of common, and the stock will be placed on the New York curb market in a few days. Later, application will be made to have the stock listed on the stock exchange.

I. A. L. Barred From Mails

(*Continued from page* 213)

"In addition to the league, Bidwell has organized and absolutely controls another corporation, namely, the International Automobile League Tire Co., whose stock, in pursuance of a contract between it and the league, the league is selling on a commission basis of 40 per cent. The par value of the stock is $100 per share. No stock is sold by the league for less than par value. The prospectuses and other publications upon which the public was induced to subscribe for the stock in the tire company contained representations which have been varied from time to time. In substance, they are to the effect that a tire factory or factories would be constructed and put into early operation, that large dividends would be paid upon the stock, that purchasers would be furnished all the tires required at actual cost of manufacture.

"The league is also engaged in selling a so-called jobbers' contract, under which the jobber is promised the tire company's tires for resale at the same price as such tires are furnished to stockholders. The undertaking of the league in this connection is subject to the following conditions: Strikes, fires, acts of God, contingencies beyond the control of the league, and its ability to fill the order. The jobber is also entitled to sell memberships on a commission basis of 50 per cent. The jobbers' contract, while a consideration of $1,000 is specified on its face, if that amount cannot be obtained, is sold for practically any sum that can be procured between $100 and $1,000."

About 1912 a reorganization committee of the stockholders of the International Automobile League Tire and Rubber Co. was formed, and after a long controversy Bidwell was finally compelled to discontinue his association with the company, it having been found that he had appropriated to his own use all the money obtained in the sale of the company's stock.

After losing control of the International Automobile League Tire and Rubber Co. Bidwell went to California and organized a corporation first known as the Western I. A. L. Purchasing Corp., the name very soon thereafter being changed to the International Automobile League Tire Co.

The memorandum further says: "The organization and conduct of the California company when compared with the organization and conduct of the Northland Co. while under the control of Bidwell clearly demonstrates the fraudulent character of his recent operations with the California company. In the promotion of the New York company the number of active members of the league, which was to furnish the market for the output of that tire company, was grossly exaggerated in order to sell the stock. Similar misrepresentations were made in the promotion of the California company. With the New York company the league received 40 per cent commission for the sale of stock. The same kind of an agreement was made between the league and the California company.

"When the organization committee took control of the Northland, although it should have been entitled to assets of some $600,000, there was not a dollar in the treasury and little or no available assets in its name. In that matter Bidwell had brought home to him in the most forcible manner the fact that his entire conduct with respect to the Northland company had been illegal, and he was forced to make restitution to the extent of over $500,000. When Bidwell was cited to appear and show cause why a fraud order should not issue against him in March of this year there was not a dollar in the treasury of the California company, notwithstanding the fact that over $112,000 had been actually taken in cash on the sale of the stock, not including 40 per cent commission paid to the league, all of which had been appropriated by Bidwell through various means, but there was also a charge against the California company of something like $192,000 by the league on account of various items, many illegal.

American Corp. Car Is a Six

Will Use 3 by 5 L-Head Block Amco Engine—45 Hp. at 2100 R.P.M.

PLAINFIELD, N. J., Aug. 7—A six-cylinder car will be marketed by the American Motors Corp., which has erected a plant at this city. It is expected that the first cars will be finished in the fall. They will be equipped with the Amco motor, built by the Amco Motor Co., South Norwalk, Conn. This is a 3 by 5 L-head block design, stated to develop 45 hp. at 2100 r.p.m. It has pump cooling, three-bearing crankshaft, two-unit lighting and starting and three-point suspension. Louis Chevrolet, well known as a racing driver and developer of speed cars, is chief engineer and vice-president.

McCord Capital Now $2,500,000

DETROIT, MICH., Aug. 8—The McCord Mfg. Co., which makes radiators and other specialties for the automobile trade, has increased its capital stock from $1,000,000 to $2,500,000, of which $2,000,000 is common. None of the stock has been or is for sale. The company's business has been steadily growing and is said by officials to be in a most satisfactory condition. It is likely that ere long it will be necessary to add to the plant's production facilities through the erection of several additions.

Page Co. Plans Ford Starter

ADRIAN, MICH., Aug. 7—The Page Fence Co., which has been making windshields, is to begin soon the manufacturing of a starter and light regulator for Ford cars. The company has made an arrangement with the inventor, B. S. Baldwin, Hicksville, Ohio, to that effect, it is said. In the windshield department, work is being rushed, as orders on hand are at least 50 per cent ahead of what they were at this time a year ago.

Hub Gas-Electric Truck Started

COLUMBUS, OHIO, Aug. 5—The Hub Motor Truck of Columbus, manufacturing a gasoline-electric commercial vehicle, has now started to manufacture its first truck, which will have a capacity of 2½ tons. This will be completed by fall, and tested for experimental purposes.

9 Out of 59 Bills Allowed to Pass in Bay State

BOSTON, MASS., Aug. 5—Fifty-nine measures relative to motor vehicles were introduced in the Bay State Legislature this year, according to the report of Sec.

James Fortesque of the Massachusetts State A. A. Mr. Fortesque's report covers the legislative work of this organization. He is assisted by James T. Sullivan, Bay State A. A., and John B. Sullivan, Jr., Boston Automobile Dealers' Association, in preventing drastic legislation.

When it is considered that out of that number there were only nine measures passed, and of that nine but one was against the motorists, it shows that the legislative committee did excellent work. The one bill against which the motorists worked in vain made more stringent the law for reckless and intoxicated drivers, but it is so worded that it makes no distinction between a man who has taken one glass of beer and the fellow who is incapable of handling a car, nor between the really reckless driver and the man who may go a mile faster than the law allows.

All the other laws enacted were advocated by the motor organization.

One of these called for lights on all vehicles using the highways to be lit uniformly from ½ hr. after sunset to ½ hr. before sunrise. In other years the horse-drawn vehicles were lighted 1 hr. after, and the motor vehicles ½ hr. A law was passed also compelling all vehicles that have become stalled, or stop on a road at night for any reason, to show two white lights.

The nuisance caused by contractors spreading tar and oil over the entire surface of the highways has been made an offense now, and the new law provides that only one-half the width of the road be so treated at one time, thus allowing vehicles to pass without danger from skidding or occupants getting all over tar and oil. There was passed also a law allowing owners in other states within 15 miles of the boundary of Massachusetts to register in the Bay State for a $2 fee. Another bill allowed all the motor vehicles of a city or town to be registered for a fee of $2. In the past some paid a full rate according to horsepower and others did not pay anything.

—

Lancaster Can Use Midgley

LANCASTER, OHIO, Aug. 5—The Lancaster Tire & Rubber Co. has the right to continue the use of the name of Midgley, the petition of Thomas Midgley, Sr., for an injunction restraining the company from the alleged use of his name having been refused by the court.

Armored King Tested by U. S.

Severe Hills and Ditches Used by Marine Corps to Test War Vehicle

WASHINGTON, D. C., Aug. 5—A test on an armored car mounted on a King eight-cylinder chassis was successfully held this week in Washington. The conditions which the car had to meet were equivalent to those of severe active service and the affair was in the nature of a demonstration to army officers of the U. S. Marine Corps. A severe climb over jagged rocks had first to be negotiated. This was up a grade of 18 per cent, full equipment being carried. Then came a climb up a tortuous sand hill in which there were sunken boulders, tree tops, etc., to interrupt the passage of the car. Finally a test was made in the ravine used for trying out the army motor trucks. At the bottom of this there is a drop of 4½ ft. into a water-filled ditch and the car was compelled to drag itself out of this with the front wheels in the mud and the rear wheels on the bank above.

Those who witnessed the test were Major Casad of the Ordnance Department, and Captains Williams and Ellis of the Marine Corps. The car was built by the Armored Motor Car Co. of Detroit and is mounted on the stock King eight-cylinder chassis. It has now been taken to Philadelphia, where it will be put through a series of tests approximating actual warfare conditions, even being placed on a battleship, taken to sea and accompanying a landing party.

—

Gasoline Down 1 Cent

(*Continued from page* 211)

steadily declining prices for all crude oils. There will be a very decided drop in the price of gasoline this month if the prediction of the Federal Bureau of Mines is correct. The prediction is based upon the report of bureau agents who state that new wells are being opened and that all existing wells are being worked to capacity.

It is also reported here that the Federal Trade Commission investigation of the Standard Oil Co. will disclose no illegal activities, although the Commission's report will show strong evidence of greed on the part of some oil men. It is also understood that the commission found that approximately twenty directors controlled the different gasoline companies and that gasoline could be sold with profit at 17 cents.

—

Petroleum Output Worth $179,462,890

WASHINGTON, D. C., Aug. 7—More crude petroleum was marketed in the United States in 1915 than in any other year of the industry, the increase being about 6 per cent over 1914. In actual figures the quantity was 281,104,104 bbl. valued at $179,462,890. The average price received at the well for this output was 64 cents a barrel.

—

Gasoline from Canadian Shale?

OTTAWA, ONT., Aug. 5—A proposal to get gasoline from the shale of Canada is now being put before the government. These oil-bearing shales are located in New Brunswick, in parts of Saskatchewan and Alberta, and to some extent also in British Columbia. It is stated by those in favor of the project that the resources are rich enough to more than provide for all the Canadian requirements. The oil imports from the United States are increasing by large amounts every year as the Canadian consumption increases. The price of gasoline in Canada is advancing steadily, and the shale-oil project is being put forward as a measure of relief.

The armored car body mounted on the standard King chassis going through strenuous tests conducted by United States army and naval officers

To Boom Guayule Rubber

Rockefeller-Aldrich Interests Plan to Develop Cultivation of Shrub in Texas

MARATHON, Tex., Aug. 5.—Rubber from Texas is the plan of the Rockefeller-Aldrich interests which have been operating in Mexico manufacturing guayule rubber. This organization intends to turn its facilities to the guayule shrub, which grows in this part of the upper border region of Texas. The only factory in the United States for extracting crude rubber from this plant is located at Marathon and it has been operated intermittently for several years, having practically exhausted the shrub in this section.

There are millions of acres of semi-arid land in this altitudinous part of Texas that are admirably adapted for growing guayule.

The Rockefeller-Aldrich interests, operating under the name of the International Rubber Co., which has its principal offices in New York, are also preparing to engage in the growing of the guayule shrubs and the manufacture of crude rubber in Arizona, according to an authoritative announcement which has just been made here by a representative of the company. It is stated that it has purchased 100,000 acres of land belonging to the Canoa Ranch, situated in the Santa Cruz valley, 20 miles north of Tucson, and that it will immediately plant about 10,000 acres in the guayule shrubs. The stock will be obtained from a nursery which the International Rubber Co. established more than a year ago.

Materials Markets Inactive

NEW YORK CITY, Aug. 8—The automobile materials market was dull and inactive during the past week, most of the commodities remaining practically unchanged. The most important feature, to car owners, at least, was the cutting of crude prices 10 to 20 cents with the resultant decline of gasoline 1 cent per gallon and the prediction that further reductions are not far off. The higher steel prices, on the other hand, give the manufacturers some concern, Bessemer having gone up $3 a ton. Cottonseed oil gained 6 cents a barrel and linseed oil picked up 2 cents. Lead lost 25 cents per 100 lb. and tin 50 cents. Rubber prices were steady, Up-river Para losing 1 cent and Ceylon first later ½ cent per pound.

McGraw Rubber to Redeem $475,000 Preferred

EAST PALESTINE, OHIO, Aug. 7—The McGraw Tire & Rubber Co., will redeem $475,000 of its preferred stock at 110 with accrued interest. This is part of a refinancing scheme and is part of a big deal in which 1,000,000 of 7 per cent cumulative preferred stock has been sold to the Maynard H. Church Co., Cleveland. The capacity of the plant is said to be 5000 tires a day and it is estimated that $4,000,000 business done during 1915 will be doubled for 1916.

$1,500,000 Tire Co. Incorporated

DOVER, DEL., Aug. 4—The Post Tire & Rubber Corp. has filed a charter to make and deal in automobile tires with an incorporation of $1,500,000 under the laws of Delaware. The incorporators are W. F. O'Keefe, G. G. Steigled and E. E. Wright.

Plymouth Castings Doubles Plant

PLYMOUTH, MICH., July 28—The plant of the Plymouth Motor Castings Co. is to be enlarged. The plans include doubling the capacity of the concern.

Warner Adds Heavy-Duty Trailers

BELOIT, WIS., Aug. 4—A. P. Warner, formerly of the Warner Auto Meter, will shortly put on the market heavy duty trailers of 2, 3 and 5-ton capacity. The Warner trailer coupling will also be manufactured and is expected to be used as standard equipment on several well-known trucks. The Warner Prairie Schooner and trailers are made by the Warner Mfg. Co.

50% Gain in Southwest Car Sales

20 Los Angeles Dealers Report Increase of 109% in First 7 Months of 1916

LOS ANGELES, Cal., Aug. 4—Automobile sales throughout Southern California and Arizona have been 50 per cent better this summer than last. This figure is reached from a canvass of twenty of the largest dealers in Los Angeles, and is in spite of the fact that it has been difficult to secure the 1917 shipments in many instances.

Taking the figures of the same twenty dealers, representing the trade in Los Angeles, for the first 7 months of 1916 and comparing these with the figures of the same dealers for the corresponding period of 1915, an increase of 109 per cent in volume of business is shown. This increase has been steady. Each month of this year has been well ahead of the same month of last year. Four houses reported greater sales during the month of June alone than during the entire first half of last year.

By actual count, one of the largest houses in the Southwest has done just double the amount of business in the first 7 months of 1916 that was done in the same period of last year, and the increase represents 200 cars, sold and delivered at retail, with another 300 cars delivered through agents in Arizona and southern California towns.

In arriving at the totals, the dealers used only sales of new cars actually sold and delivered, and paid no attention to the orders from agents and private buyers on file.

Houghton Buys Ohio Tractor Co.

MARION, OHIO, Aug. 4—W. H. Houghton, president of the Houghton Sulky Company, has purchased at receiver's sale the personal property of the Ohio Tractor Mfg. Co., which includes the material on hand, finished product, machinery, patterns and patents, which have been in the hands of Charles H. Lewis as receiver.

Mr. Houghton may go on manufacturing tractors, using the patterns of the Ohio Tractor Mfg. Co. It is understood that Mr. Houghton and his associates will purchase the building from the receiver. The company will be reorganized by the election of Ellis H. Houghton as general manager of the tractor concern.

General Rubber Increases Capital

AKRON, OHIO, Aug. 5—The General Tire & Rubber Co., this city, has increased its capital by 150 per cent. The capitalization is $500,000; was $200,000.

Security Prices Are Lower

Chevrolet Declines 21 Points, Saxon 7 and Overland 6⅜—List Is Weak

NEW YORK CITY, Aug. 8—The announcement of lower prices for Ford cars, and numerous rumors to the effect that other companies' earnings would be materially affected, as well as others predicting other price reductions, served to render the automobile and allied stocks the weakest group on the list during the past week. In spite of record earnings reported by several of the leading companies of the industry, the stock quotations showed practically no effects of the optimism which they would naturally be expected to arouse. On several occasions the bear element directed raids against one or more of the automobile stocks with the result that prices sagged and sank, recovering now and then but ending the week substantially below the quotations at the end of the previous 7-day period.

Many Large Declines

A glance at some of the more striking price changes will suffice to reveal the general character of the market. Chevrolet lost 21 points, declining from a bid of 208 to 187, the preceding week having seen a loss of 8 points. Saxon went down 7 points, Overland common 6⅜, Packard and Chalmers common issues each lost 5 and United Motors declined 4½. The only stocks to show any strength were the tire issues, Miller gaining 25 points, Swinehart 15 and Portage 2.

On the Detroit exchange there was comparatively little activity, General Motors losing 10 points on the common and Maxwell 4, Studebaker common 3½ and Kelsey Wheel 294, the latter following a decline of 100 last week.

Stromberg Refinancing Completed

NEW YORK CITY, Aug. 7—Final details for the financial expansion of the Stromberg company were completed last week in New York. As reported 2 weeks ago, the Stromberg Motor Devices Co., Chicago, with a capital of $50,000, has been taken over by the Stromberg Carbureter Co. of America, recently incorporated in New York with a capitalization of $5,000,000. The directors of the new company are Charles A. Brown, Charles W. Stiger, William L. O'Neill of Chicago, H. E. Gunnison, C. L. Saylor, Allan A. Ryan, of New York, and Harry E. Stutz, of Indianapolis. Mr. Stiger, president of the old company, becomes president of the new one and Mr. Ryan becomes vice-president, these two, with Mr. Gunnison composing the executive committee.

Same Officers

The officers remain as before except that Ryan replaces Carleson as treasurer. There will be no change in the policies of the company. Factory capacity is being doubled.

Republic Truck Has Bonus System

Rewards Employees for Working Toward Standard Time for Each Operation

ALMA, MICH., Aug. 5—The Republic Motor Truck Co. has adopted a bonus system in its plant whereby it expects to bring about a great increase in production, and at the same time enable its hundreds of shop workers to earn a great deal more than their present wages.

A standard, or unit of time has been established for each and every operation, and employees are urged to work toward that standard, with the end of attaining greater efficiency and greater wages. The man who reaches this standard, or unit will be rated 100 per cent efficient, and those who become 75 per cent efficient, or are able to complete one operation in three-quarters of the time set by the standard, or unit, will be placed at once upon the bonus list.

The rate of the bonus for 100 per cent efficient men is to be 20 per cent of the daily wages. With the increase of the efficiency of the employee and, of course, the increase in the amount of his actual production, comes an increase in the rate of the bonus. No limit will be placed on the amount of work an employee can do, as is the practice in many factories and no change in the limit for 1 year.

Close Dealers' Contracts at Missouri Tractor Show

(*Continued from page* 213)

and even Texas and Kansas. Here we have no great areas to be broken such as there are in Texas, for example. Nor do we have the extreme climatic conditions that make the Texas farmer's life a burden and kill off his horseflesh.

Missouri is essentially a state of moderately small farms. All told, according to the latest available figures, there are some 277,244 separate farms in the State. The average size per farm has been computed to be about 125 acres, and the average value per farm is in the neighborhood of $7,400.

Farms Big for One Man

It is peculiarly a condition in Missouri that a great many of these farms are just slightly too large for one man to work, yet they are not sufficiently profitable to warrant the employment of help. It is expected that the small tractor will be of inestimable value because of these conditions and because it will then permit one man to work his farm, to get better crops from it and larger crops. Whether it will get larger crops is problematical. Statistics do not show that a man who purchases a tractor gets larger crops from his land though they do show that when a man purchases a tractor he generally increases his land holdings. But figures almost invariably show that the tractor improves the value of the yield and so increases the farmer's profit.

Another important bearing which the tractor will have in Missouri, because of what may be termed the uneconomic size of farms in general is that it will permit the work on these farms to be done at just the proper time. Where a man has a farm that is slightly too large for him to handle himself, or is, perhaps, just about as large as he can handle, weather conditions often will make it necessary for him to delay putting in his crops at the proper time. Some of the crop will be too early for the normal market and some of it will be too late. The result often is a dead loss of several hundred dollars. The tractor will save this because all the work can be done at the proper time.

Corn the Main Crop

Corn is the big crop in Missouri, with blue grass second and stock raising third. This year it is estimated that the state will market about 200,000,000 bushels. This week there has been heavy rain through the corn belt and it has come at the proper time. In a great many cases corn has been put in late and rain at this time will insure a nearly normal crop.

The demonstration here has not been as well attended as have previous demonstrations but there are several reasons for this. The first is that most farmers are busy at this time getting their corn in. This was put in late and now is being harvested. A second reason is that on Tuesday there was a primary election, which naturally kept the farmers at home. Another reason is that the demonstration field, which is in Kinloch Park, is 16 miles from the city and the transportation facilities are not all that might be desired. It is expected that later in the week the farmers will flock to the field and that dealers and distributors also will put in an appearance.

Unfortunately—here again is demonstrated the smallness of Missouri farms—it was not possible for those in charge of the demonstration to secure one large field, as in Dallas and Hutchinson, where all the machines might plow at once. Ground for plowing is limited and for this reason many of the companies are compelled to demonstrate only their small machines. Some of the machines are in one field and the remainder in another field, perhaps a quarter of a mile distant. At least the smallness of the available field has had the advantage of bringing into prominence the work of the smaller tractor and in the opinion of agricultural experts it is the small tractor that Missouri must look to for the most part.

Kerosene is used somewhat more extensively here than at either Dallas or Hutchinson. During the first day of plowing thirty-three of the machines were working on kerosene as against twenty-one operating on gasoline.

The accessory exhibit, instead of being in one large tent, as heretofore, is in two tents and is attracting quite as much attention as in Dallas and Hutchinson.

French Adopt Uniform Carbureter

(*Continued from page* 212)

liters to 31 liters. The Sterling is not used very extensively in the French army, and no army records have been made of its consumption, but there are more than 100 of them employed by the munition factories around Paris. The first attempt to economize was made by Chief Engineer Michelat of the Delage factory, who cut his gas from 11 to 6.6 gal. per 100 kilometers. This example was followed by other users, until about sixty of these trucks have been converted to European carbureters.

Pierce Holds Tests

Complaints of high gasoline consumption having been brought to the notice of the Pierce-Arrow engineers in France, it was decided to hold a comparative test in order to show that the high consumption was not due to any fault in the truck or the carbureter. Two of the factory representatives took ordinary trucks in army service, obtained the proper carbureter adjustment and took their place in a convoy driven by soldiers and commanded by an officer. The factory men had to maintain their place in the convoy, were not allowed to coast on hills, and had no fitments not on the other trucks in the convoy. For the 5-ton models the average for the soldier-driven trucks was 4.7 miles to the gallon; the average for the two factory driven trucks was 7.8 miles to the gallon. Similar tests were made with 2-ton trucks, the results being 7.12 miles to the gallon for the soldier-driven trucks and 8.74 miles for the average of the two vehicles driven by the factory representatives. Translations have been made on the basis: 1 American gallon = 3.79 liters.

Hyatt Sends Party to Tractor Meeting in Private Car

CHICAGO, ILL., Aug. 5—The Hyatt Roller Bearing Co. has arranged for a special private car to convey some of its representatives and a party of engineers and friends from Detroit to the national farm tractor demonstration which opens at Fremont, Neb., to-morrow. The car will leave Detroit to-night, and reach Chicago to-morrow morning. Tuesday will be spent in Chicago, with headquarters at the Hotel Blackstone. The party will leave at 6.05 p. m. on Tuesday, arriving at Fremont Wednesday morning. Following are those who will make up the party:

George W. Dunham, Society Automoblie Engineers; A. P. Sloan, Jr., general manager Hyatt Roller Bearing Co.; C. W. Nash, Nash Motors Co.; G. S. Mott, Western Mott Co.; C. S. Kettering and E. A. Deeds, Dayton Engineering Laboratories Co.; John W. Bate, Micheli Motors Co.; Harry Bassett, Weston-Mott Co.; C. L. Barnes, Barton W. Currie, *Country Gentleman;* Henry Ewald, Campbell Ewald Co.; P. G. Koether, general sales manager automobile department Hyatt Roller Bearing Co.; R. L. Lane, chief engineer Detroit office, Hyatt Roller Bearing Co.; J. G. Weiss, works manager, Hyatt Roller Bearing Co., Newark, N. J.; C. M. Eason, manager tractor bearing department Hyatt Roller Bearing Co., Chicago.

In addition the following Hyatt representatives will be at the Fremont demonstration: H. O. Kuchemmeister, assistant sales manager; H. M. Carroll, advertising department; O. W. Young and J. R. Bateman, sales engineer; J. E. Martin, dynamometer department; L. S. Newman, mechanical inspector.

Ford Tractors at Fremont

DETROIT, MICH., Aug. 7—Henry Ford and his son attended the Fremont, Neb., national tractor demonstration with three of Ford's new machines. Ford and his son traveled to the demonstration in a private car. The three tractors are of exactly the same type, but operate on gasoline, kerosene and alcohol respectively. In addition to the tractors, Ford also brought a comprehensive display of the various parts which enter into the construction of this machine.

Factory Miscellany

Diamond Chain to Build—The Diamond Chain & Mfg. Co., Indianapolis, Ind., will begin the erection of a complete manufacturing plant on the 6-acre tract of land which it acquired 4 years ago, located on Kentucky Avenue. The plans contemplate a concrete structure containing four stories with 150,000 sq. ft. of floor space. The new building will be 380 by 60 ft. with two L's, 100 ft. long making the entire frontage 700 ft.

To Make Vulcanizers—F. A. Whitten, Charles Palmer and A. Lewis have organized a company in Grand Rapids, Mich., for the purpose of manufacturing vulcanizing machines.

Haynes Makes Sixth Addition—The Haynes Automobile Co., Kokomo, Ind., is starting the sixth factory addition built during the past year. The new building, a two-story structure to house the repair department, will bring this year's increase in floorspace to a total of 180,000 sq. ft. The latest addition will be ready for occupation Sept. 1.

Seat Co. Makes Ambulances—Construction of motor ambulances is the latest addition to the factory of the Excelsior Seat Co., Columbus, Ohio, the first vehicle turned out by the firm having been placed in the service of the Second Ambulance Co. of the troops now at the mobilization camp. Several months ago this manufacturing company, which for years has been making buggy seats and buggy bodies, installed new machinery and began the manufacture of automobile bodies. A regulation Ford chassis was rebuilt so that it has a wheelbase of 130 in.

American Forging Adds Again—The American Forging & Socket Co., Pontiac, Mich., maker of small motor vehicle forgings and automobile top accessories, is rushing the construction work on an 80 by 100 ft. building, the second large addition to its plant since the first of the year. Other additions are also planned.

Holt-Welles to Expand—The Holt-Welles Co., New York City, will increase its capital from $50,000 to $200,000, as a result of plans for increasing both the manufacturing and distributing facilities for Browne and Browne-Branford carbureters, for which this company is sole selling agent.

E. H. Stickels will remain president of the company, with the sales work under his direct supervision. A. B. Browne, designer of the carbureter and consulting engineer for the Malleable Iron Fittings Co., where the Browne carbureters are made, will have entire charge of the laboratory and experimental work.

Holihan Mfg. Co. to Build—The Holihan Mfg. Co., Detroit, Mich., has bought 3½ acres of ground on Milford Avenue and Pere Marquette Railroad and has let the contract for the immediate erection of a large factory, 80 by 400 ft., with adjoining buildings for steel storage, shipping and enameling. The new plant will be occupied by September, and the production will be doubled.

This is the second time the company, which manufactures hoods, tanks, fenders, and stampings, has been compelled to seek larger quarters and it will employ about 500 men in the new plant.

Republic Truck to Build—The Republic Motor Truck Co., Alma, Mich., will erect two new factory buildings in which to manufacture the new Model 9 ½-ton truck.

The new buildings, are to be erected just east of the old plant and will extend from Michigan Avenue along Bridge Street to the river. The main structure is to be 60 by 1000 ft., and one story high. Parallel to the large building will be built a stockroom 36 by 500 ft. The two buildings will have a floorspace of 48,000 sq. ft. and will cost about $38,000. The company at present employs 700 men in the old factory, and this number will be practically tripled upon completion of the new buildings and as soon as the new model gets well under way.

The Automobile Calendar

ASSOCIATIONS

Aug. 15—Metropolitan Section, S. A. E. Meeting at Automobile Club of America. Subject, "South America."

Aug. 28-Sept. 1—Milwaukee, Wis., Booster Tour of Milwaukee Automobile Dealers.

Sept.—Indianapolis. Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.

Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.

Oct. 13—Flint, Mich., Fall Meeting National Assn. of Automobile Accessory Jobbers.

Dec. 2-9—Electricians' Countrywide Celebration.

CONTESTS

Aug. 11-12—Pikes Peak, Col., Hill Climb, Pikes Peak Auto Highway Co.

Aug. 12—Portland, Ore., Track Race, Hiller-Riegel Co.

Aug. 18-19—Elgin Road Race, Chicago Auto Club.

Aug. 26—Kalamazoo, Mich., 100-Mile Track Race.

Sept. 1-2—New York, N. Y., Sheepshead Bay Speedway, 24-Hour Race, Trade Racing Assn.

Sept. 4—Elmira, N. Y., Track Race, Elmira Auto and Motorcycle Racing Assn.

Sept. 4—Cincinnati, Ohio, Speedway, Cincinnati Speedway Co.

Sept. 4—Newark, N. J., Track Race, Olympic Park, Racing Assn.

Sept. 4—Des Moines Speedway Invitation Race. Limited to six entries.

Sept. 4-5 — Spokane, Wash., Track Race, Inland Auto Assn.

Sept. 9—Indianapolis Speedway Race.

Sept. 16—Providence Speedway Race.

Sept. 18—North Yakima, Wash., Track Race, Washington State Fair.

Sept. 29—Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.

Sept. 30 — New York City, Sheepshead Bay Speedway Race.

Oct. 7—Philadelphia Speedway Race.

Oct. 7—Omaha Speedway Race.

Oct. 14 — Chicago Speedway Race.

Oct. 19—Indianapolis, Ind., Race, Indianapolis Motor Speedway.

Oct. 21 — Kalamazoo, Mich., Track Races, Kalamazoo, Motor Speedway.

Oct. 22-23—Los Angeles, Cal., Commercial Car Reliability Tour.

Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

GOOD ROADS

Sept. 1-9—Cincinnati, Ohio, Good Roads Exposition and Convention, Music Hall, Hamilton County Dixie Highway Council of Cincinnati.

Sept. 6-7—St. Paul, Minn., Good Roads Congress, Auditorium.

SHOWS

Aug. 7-19—Atlantic City, N. J., First Show, Young's Pier.

Sept. 2-9—Cleveland, Ohio, Show, Industrial Exposition and Fair, Edgewater Park.

Sept. 2-9—Columbus, Ohio, Fall Show, Ohio State Fair, Columbus Automobile Show Co.

Sept. 4 - 8 — Hartford, Conn., Show, Connecticut Fair Assn.

Sept. 4-11 — Indianapolis, Ind., Show, Indiana State Fair, Indianapolis Automobile Trade Assn.

Sept. 10-16 — Milwaukee, Wis., Show, Wisconsin State Fair, Machinery Bldg.

Sept. 25-30—Salem, Ore., State Fair, Joseph M. Rieg, manager.

Oct. 14 - 31 — Dallas, Texas, Show, State Fair.

Jan.—First Pan American Aeronautic Exposition, New York City; Aero Club of America, American Society of Aeronautic Engineers, Pan-American Aeronautic Federations.

Jan. 6-13, 1917—New York City, Show, Grand Central Palace, National Automobile Chamber of Commerce.

Jan. 13-20 — Montreal, Que., Show, Montreal Automobile Trade Assn.

Jan. 27-Feb. 3, 1917 — Chicago, Ill., Show, Coliseum, National Automobile Chamber of Commerce.

Feb.—Newark, N. J., Show, First Regiment Armory.

Feb.—St. Louis, Mo., Show, Auto Manufacturers and Dealers' Assn.

TRACTOR

Aug. 7-11—Fremont, Neb., Tractor Demonstration.

Aug. 14-18—Cedar Rapids, Iowa, Tractor Demonstration.

Aug. 21-25—Bloomington, Ill., Tractor Demonstration.

Aug. 28-Sept. 1—Indiana Tractor Demonstration.

Sept. 4-8—Madison, Wis., Tractor Demonstration.

Sept. 11-16 — Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.

The Week in the Industry

Goodyear Makes Appointments—The Goodyear Tire & Rubber Co., Akron, Ohio, has appointed the following: M. D. Montgomery, who has been acting manager of the Denver district during the illness of the late S. E. Gillard, has been confirmed as manager of that district.

F. C. Meyer, who has been in charge of the Des Moines branch, becomes manager of the Minneapolis branch vice G. H. Barmore, who has been appointed manager at Milwaukee.

F. W. Telford, former supervisor of motor truck sales at Chicago, becomes manager of the Des Moines branch.

T. J. Fitzgerald will fill the managership of the El Paso branch left vacant by the death of F. G. Dennis.

Gibson Heads Edison in West—F. C. Gibson has been appointed Pacific Coast manager for the Edison Storage Battery Co. with headquarters at 65 Columbia Street, Seattle. The new firm, which will handle the agency for the Edison line in Washington, Oregon and Idaho, will be known as the Edison Storage Battery Supply Company. Mr. Gibson formerly held the agency for the Edison Storage Battery line in the State of Oregon.

Jones Joins Budlong—H. W. Jones, Hartford, Conn., has resigned as sales manager of the Britton Co., Stearns-Knight distributor, to become associated with Milton J. Budlong of the firm of Gaston, Williams & Wigmore, 140 Broadway, New York City. Mr. Jones was formerly secretary of the Columbia & Electric Vehicle Co. and later associated with the New Haven Carriage Co.

Thompson Returns to Detroit—E. E. Thompson, at present connected with the branch of the Maxwell Motor Co. in San Francisco, will return to Detroit in September to assume the duties of sales superintendent of the Maxwell Motor Co. for the Pacific Coast.

Sell Cars Day and Night—The local retail branch of the Studebaker Corp., Los Angeles, Cal., has inaugurated a day and night selling system. Beginning July 24 the salesroom has been kept open day and night and the sales force has been reorganized accordingly so that the men work in regular shifts.

Johnson Joins Monroe—T. S. Johnson, for the past 2 years branch manager of the Oakland Motor Car Co. branch in Philadelphia, has been appointed eastern distributor by the Monroe Motor Co., Pontiac, Mich., with headquarters in Philadelphia.

Reo Opens Branch in Chicago—The Reo Motor Car Co. has purchased the business of Owen & Buxton, Chicago Reo dealers, and will operate as the Reo Motor Car Co. of Illinois.

Twin City News—The Maxwell Motor Co., Inc.. has opened a factory branch at 134-136 West Seventh Street, St. Paul, with J. W. Martin as manager.

The Ford Motor Co. has opened a factory branch in St. Paul. Heretofore it has been operated from Minneapolis. W. H. Schmelzel has been transferred from the branch at Fargo, N. D., to succeed A. H. Sargent as manager here. The latter is transferred to Grand Rapids, Mich. W. P. Winders is advanced to manager at Fargo and F. C. Seiss, superintendent there, has been made assistant manager at Sioux City.

Northwest News—W. J. Doyle and S. J. Doyle of Carrington, N. D., have formed the Overland-Doyle Co. to manage the Overland distribution in the Fargo district. W. J. Doyle, veteran implement dealer, will move there.

The Glide Automobile Co., Inc.. has been formed by managers of the Avery Co. and others to manage a factory branch of the Glide car. Its territory will be western Minnesota, North Dakota and eastern Montana.

St. Louis Trade Items—The Moon Motor Car Co. reports shipments last month of 6-66 cars to Copenhagen, Denmark and to Valparaiso, Chile. and a 6-43 to Pahiatua, New Zealand. The latter car was ordered by cable. which also gave notice that the Barlow Motor & Cycle Co. of that place had been made agents for the north section of the island. The car went to San Francisco for boat shipment, the total journey being 8500 miles.

Geller, Ward & Hasner, St. Louis, hardware firm that recently took the agency of the Hood tires and which handles many accessories, has opened an uptown store at 3328-32 Olive Street, where the automobile lines will be handled exclusively. Complete lines will be handled at the Fourth Street store.

Moerschell Electric & Supply Co., St. Louis, announces that P. J. Newsom has been made manager of the service department.

Supreme Motor Car Co., St. Louis, recently organized to handle the Simplex cars has opened show-rooms at 3019 Locust Street.

G. F. Farasey, with the Kelly-Springfield Tire Co. at Boston and Cleveland, has taken charge of the St. Louis branch for the same company, succeeding C. R. Higgason.

The Prest-O-Lite Co. announces the immediate construction of a building for its especial use at Locust and Beaumont Streets, St. Louis. The office will be on the Locust Street front and in the rear will be a service station for all Prest-O-Lite products. There will be a large driveway for cars midway of the building on Beaumont, so that automobiles to be served can enter the building. The building will be ready Sept. 1. The St. Louis station now is at Locust and Thirty-fourth Streets.

New England Trade Items—The E. R. Benson Motor Car Co., Portland, Me., has promoted C. A. Laidlaw, its retail sales manager, to be the wholesale man for Maine.

T. F. Russell has taken the agency for the Inter-State line at Springfield, Mass.

G. J. Coleman, for 2 years with the sales force of the F. W. Roberts Auto Co., Northampton, Mass., has taken the agency for Studebaker cars in Hampshire County, with headquarters in that city.

F. H. Kenny, who has the Chalmers agency at Worcester, Mass., has taken a 5-year lease of new salesrooms on Main and Oread Streets.

Edward Cross has been appointed New England traveling representative in charge of the entire district by the Hood Rubber Co., maker of Hood tires at Watertown, Mass.

The Packard Motor Car Co., Boston, Mass., has approved plans for a service station on Shrewsbury and Atchison Streets, Worcester, Mass., that will be the largest building of its kind in that city.

C. L. Lowd, for some time with the Oldsmobile company of New England, has been appointed assistant general manager.

The Maxwell Motor Sales Corp. at Providence, R. I., has appointed T. A. Clarke to its salesforce. He was formerly with the Crow Motor Sales Co. at Washington, D. C.

The Stoddard Motor Car Co., Springfield, Mass., that handled the Pierce-Arrow line for many years until a few weeks ago, has now taken on the Locomobile and Riker truck agency.

The International Motor Co. of New York has opened a branch for Mack trucks at 101 Liberty Street, Springfield, Mass.

Ford to Drop Retail Sales

To Market Cars in Same Way as Plows and Other Hardware — Dealers to Have No Territory Rights

DETROIT, Aug. 14—The Ford Motor Co. will discontinue the selling of cars at retail, although it will probably be some little time before the new plan of marketing is worked out completely. Briefly, the new merchandising scheme is similar to the methods of distributing any manufactured article, in that the actual distribution to the ultimate users will be through dealers who will have no exclusive territory rights and who will be allowed to sell the machines anywhere or everywhere. The many Ford branches throughout the country are to be nothing more than assembly stations and wholesale distribution points to these dealers. The dealers in turn will be required to maintain regular Ford service and garage methods.

It is believed that the Ford car to-day is well-nigh a standard product, just as a lawn-mower or other implement might be regarded, and nearly everyone who knows anything about machinery or mechanical matters should be able to take care of it and do ordinary repairing. With this thought in mind the service matter clarifies greatly, and with the wholesale branch near by it is no great problem to take care of any condition in connection with the car that may arise. The dealer will have the branch from which he bought his cars to fall back upon in every way, and he will also get all his parts through that branch.

In short, the new Ford selling methods are revolutionary, so far as the automobile industry is concerned, but they are the principles of merchandising any standard article of commerce. Take any piece of merchandise, such as any of the well-known brands of breakfast food, for instance. The maker of this distributes to jobbers, who in turn supply the grocers, and any grocer can get a stock with no restrictions as to where he sells. Suppose we consider the marketing of plows. If a certain man with a general store wants to handle a line of plows he can secure such merchandise with no territory restrictions. The store across the street might also carry the same make of plow for his trade.

So with the sale of Fords. The Ford branch houses in all parts of the country will distribute the finished cars to the dealers at wholesale, and one garage might handle them across the street from another. Each would retail them to his own trade. These retailers of Fords will, of course, have to be reputable dealers before they can get a supply of cars and they will have to contract to give recognized service, but they can sell anywhere they are able to sell.

No information as to the number of cars a dealer will have to buy in order to get them through the branch at wholesale

Haynes Declares 108% Stock Dividend

KOKOMO, IND., Aug. 12—The Haynes Automobile Co., this city, declared a stock dividend of 108 per cent at its annual meeting on Aug. 8 in this city. The capital stock was increased from $1,400,000 to $4,000,000, and it was decided to proceed immediately to the erection of a new factory that will turn out the light sixes.

Net earnings of $1,600,000 are reported. The company built 6700 cars and will be able to produce 12,000 the ensuing year, 3000 of which will be twelves and the remainder sixes.

The directors re-elected Elwood Haynes, president; Stephen Tudor, secretary; A. E. Starbuck, treasurer, and A. G. Seiberling, general manager.

90,000 People See Ford Tractors

Fremont's Tractor Show Rivals Metropolitan Automobile Exhibits in Interest and Attendance

FREEMONT, NEB., Aug. 11—Nearly 90,000 interested farmers and friends have been in this town the last 3 days to see the annual tractor demonstrations and incidentally get their first glimpse of Henry Ford's new tractor that has been looked for for over a year. Ford's tractor is here; so is Henry, and so is his son Etzel. As usual, Ford has come up to expectations and perhaps gone a little beyond, for his tractor will use gasoline, kerosene or alcohol. It will not make much difference whether gasoline continues to go up or down, for the machine performs equally well with any of the three fuels.

In price it has already worsted Ford's new automobile schedule, as rumor has it placed at $300, although definite figures have not been announced. The tractor is very light, weighing less than a ton.

You cannot mistake Ford's new tractor from being a Ford machine. It has a lot of the conventional Ford earmarks. It is a four-wheel design that can plow at 2.5 to 3 miles per hour and run along the road at 5 to 6 miles per hour, and for night plowing has a set of headlights that get current from the magneto.

The motor is a larger edition of the Ford passenger car motor with a block of four cylinders, each 4 by 4.25 in., and having the familiar Ford flywheel magneto, thermo-syphon cooling, etc. From the motor there is a multiple-disk clutch, three-speed, with reverse gearset of the constant-mesh type and worm transmission to the rear axle.

As a farm implement it is capable of

Production Increasing in Mich.

Hudson, Chalmers and Reo All Speeding Up Outputs—Dealers Urging Haste

DETROIT, MICH., Aug. 15—Detroit automobile production continues to increase. Both the Hudson and Chalmers companies report large increases and are preparing to further add to their outputs. The Reo company in Lansing is also preparing for a large increase.

There are now approximately 6000 men on the payroll of the Chalmers Motor Co. The daily output is running from 125 to 150 cars, and within a short time a new schedule of more than 150 cars a day will be put into operation. It is expected that from 35,000 to 40,000 Chalmers will have been made by Dec. 31, 1916, which is the end of the 1916 fiscal year of the Chalmers company.

Since the beginning of this month production at the Hudson Motor Car Co. is averaging 150 cars a day. It is expected that this daily output will be gradually increased, as the company, which originally planned to build 35,000 sixes for its 1917 season, has increased its schedule 45,000 recently, and even this increase is reported to be below the number of cars which have been asked for by the Hudson distributers and dealers.

For the fiscal year 1917 the Reo Motor Car Co., Lansing, Mich., has laid out its plans for a production of at least 36,000 passenger cars, which is considerably more than were made during the 1916 fiscal year. The Reo Motor Truck Co. plans to build 6000 trucks, or more than twice the number made during the past season. There are now 5500 men employed at the two plants.

Wahlberg Joins Nash Motors

PONTIAC, MICH., Aug. 14—N. E. Wahlberg, chief engineer of the Oakland Motor Car Co., has resigned to become associated in a similar capacity with the Nash Motors Co., Kenosha, Wis., the new organization headed by C. W. Nash, formerly General Motors president, which company is to manufacture Jeffery cars. Mr. Wahlberg has been with the Oakland company for a number of years, first as assistant engineer and later as head of engineering.

Willard Battery Business Increasing

CLEVELAND, OHIO, Aug. 15—Four new buildings are to be erected by the Willard Storage Battery Co. in addition to the ten buildings now occupied. There are now more than 150 builders of cars and trucks who are using Willard storage batteries. One of the new buildings will contain a power house of the largest size. It will be capable of producing 40,000 amperes at 110 volts.

Buda Motors to Sell Direct

CHICAGO, Aug. 12—The Buda company is organizing a sales department and will handle the sales of the Buda motors direct, instead of through Bradenburg & Co. As head of the new motors sales department, Lon E. Smith, western representative of the Eisemann Magneto Co., with headquarters at Indianapolis, becomes sales manager on Sept. 15 of the motor department of the Buda Co., and C. V. Richardson, recently chief engineer of the Republic Motor Truck Co., has become sales engineer of the Buda Co. The headquarters of the new department will be at Harvey, Ill.

Drake Returns from Orient

DETROIT, MICH., Aug. 14—After an extended trip through Japan, China and Australia, Joseph R. Drake, vice-president of the Hupp Motor Car Co., is again in Detroit, being accompanied by R. F. Cole, Hupp representative in the Orient. Mr. Drake has made a number of world tours in the interests of his company and reports conditions very favorable for extension of American car selling in those countries he visited.

Simplex to Market Its Cars Direct

NEW YORK CITY, Aug. 14—The Simplex Automobile Co., New Brunswick, N. J., has taken over the Metropolitan distribution of its car. John G. Dale, who has handled the car for several years, will take over the Jordan car and another high-priced town car, which will be announced in the near future.

The Simplex company, which takes over all of the unfilled orders and contracts, has rented for a term of 5 years the store and basement of the new building at the southeast corner of Fifth Avenue and Fifty-eighth Street and will establish there its local sales and showroom.

The Jordan car will be handled at the old location of the Simplex, 240 West Fifty-ninth Street. According to present plans, the territory included under the new arrangement will include the Metropolitan district and the surrounding territory, reaching as far as Bridgeport, Poughkeepsie, New Jersey and Long Island.

Hastings Empire Engineer

DETROIT, MICH., Aug. 14—D. T. Hastings, formerly on the engineering staff of the General Motors Co., is engineer for the Empire Automobile Co., Indianapolis.

Thianna Car Now on Market

Will Sell at $6,000—Company in Newark, N. J. and Capitalized at $500,000

NEWARK, N. J., Aug. 15—Another high-priced car will soon make its appearance in the East. This is the Thianna, which will be built in special body designs for town car use.

The Thianna car is made by the Thianna Motor Co., Newark, N. J., capitalized at $500,000, all paid in. This company has just started manufacturing and will turn out 200 cars of special body work during the first year. The car is not an assembled product and all parts will be made at the factory. The chassis sells at $3,600 and with the coupé or closed body at $6,000. T. M. Pepperday, former Simplex agent in Pittsburgh, is president.

The car has 62-in. cantilever springs and a four-cylinder 3⅞ by 6-in. four-cylinder motor. The wheelbase is 125 in.

Severe Fines in Traffic Court

NEW YORK CITY, Aug. 14—July was the first complete month of New York's experience with its traffic court, which opened June 14. A study of the accompanying tabulation will show that there has been no inclination toward leniency, Magistrate House imposing severe fines, and, in default of payment, jail sentences of 10 days or over on every driver convicted. A total of $18,610 in fines was received during the month. This money goes to the fund for policemen's wives.

N. Y. Traffic Court's First Month

Arraignments	1,280
Chauffeurs' licenses revoked	2
Owners' licenses suspended	2
Imprisoned for non-payment of fines	44
Total fines received	$18,110
Speeding, first offense	426
Speeding, second offense	32
Speeding, third offense	3
Improper license plates	116
Passing trolley cars, first offense	78
Passing trolley cars, second offense	1

Smoking	50
Court days	20
Cases per day, average	64

Buys 1915 Ford for $377

ST. LOUIS, MO., Aug. 12—Henry Schnuhr of Mascoutah, Ill., does not read the newspapers. Last Tuesday he attended a public sale at the Louis Forcade farm in his neighborhood, and bought a 1915 Ford car for $377. Not until Friday did he learn of the cost of a new one and then he consulted a lawyer to learn if there was anyway by which he could get "out of his bargain."

New Ford Radiator and Fenders

Alterations Entirely Change Appearance of Car—Moulded Unbroken Body Lines

DETROIT, MICH., Aug. 15—The new Ford for 1917 has to be seen to appreciate how greatly the few alterations improve its appearance. The average person will have to look twice to be sure it is a Ford. These changes are principally in the externals. They are:

1—*The fitting of an entirely new radiator of black enamel, which is of about the same width and height as the present one, although it has the appearance of being of slightly less thickness.*

2—*The use of a sloping hood that eliminates any break where it adjoins the body.*

3—*The addition of crowned fenders front and rear which conform to the curve of the wheels in most modern fashion.*

There is no other change. The wheelbase and body remain identical with the previous model. The new radiator shell is a stamping in two pieces: one, the shell proper and the other the top portion that bears the Ford name stamped in it. The familiar Ford filler cap and radiator spout of brass protrude at the top.

Now that the radiator is enameled, there is really very little brass about the car, only the filler and hub caps being of this metal. The shape of the new radiator is very pleasing in that there are no abrupt edges as in the type that has become familiar the world over, the new shell having rounded edges where the side parts of the shell curve into the top portion, and the front edge is also rounded over.

Louvres in Hood

The new hood is provided with louvres in the sides, and is shaped so that there is an unbroken line from the radiator to the body proper and it, as well as the radiator and fenders, have been given a high finish. The fenders are substantial pressings that are free from vibrations when in position on the car. They are well attached to the chassis and body.

Besides these external changes, which add a great deal to the general appearance of the car, there are two minor changes under the hood. One is the fitting of a shield around the fan, this concentrating the air and insuring its going to the whole of the radiator surface, as an aid to cooling, and the other is the fitting of an electric horn. This horn is mounted at the right rear side of the cylinders between them and the steering column. It is of the vibrator type and is arranged to operate from the current of the flywheel magneto. The operating button is mounted on the steering column just under the steering wheel.

New Ford touring car with altered radiator

—

NEW YORK CITY, Aug. 15—Parts for the new Ford bodies have been received in the assembly plant at Long Island City and in about 2 weeks the cars should be coming through regularly.

—

Schwarz Wheel to Expand

PHILADELPHIA, Aug. 14—The Schwarz Wheel Co. has purchased 6 acres at Holmesburg near its present plant for extensions.

—

Falls Motors Plans 120 Engines a Day

SHEBOYGAN FALLS, WIS., Aug. 12—The Falls Motors Corporation, which succeeded the Falls Machine Co., on Aug. 1, has definitely decided not to remove the plant from Sheboygan Falls, Wis., to Cleveland, Ohio, or other cities which have made offers. Additional buildings required to bring the capacity up to the requirements of contracts will be built. A large assembly shop, 250 ft. long, has been completed and work will be started at once on an addition, 120 by 180 ft., to this department. The present output of fifty engines daily will be increased to eighty before Oct. 1, and by Jan. 1 the daily capacity will be 100 motors. The assembling department, with the addition to be erected, will have a capacity of 120 motors daily. The new interests are represented on the board of directors and the official personnel remains as before, with the exception of adding a new vice-president, Leroy Miser, and an assistant secretary, J. G. Lude, formerly purchasing agent. Gustav Huette is president; R. W. Randall, first vice-president; Leroy Miser, second vice-president; Angelo R. Clas, secretary.

Standardize Truck Lever Controls

S. A. E. Truck Division Recommends Standard Gearshift Positions and Lever

BUFFALO, N. Y., Aug. 14—Standard controls for trucks which will permit any driver to change from truck to truck without trouble were recommended at a meeting of the S. A. E. Truck Standards division held here to-day.

It was considered best not to specify either right or left hand steering wheel location as this does not affect the operation of the truck if all other things are the same. Thus the recommendations are as follows:

Gearshift and hand brake levers always to be at driver's right. The gear lever nearest the driver and the brake lever to the right of the gear lever.

A latch or its equivalent for guarding the reverse slot should be provided for both three- and four-speed transmissions.

The position of the lever to give the different gears in a three-speed transmission should be the same as that already recommended for passenger cars.

In a four-speed transmission the highest gear to be in the same position as the highest in the three-speed with the same successive motions for changing down. The low gear will then occupy the place taken by the reverse in the three-speed transmission. No particular position specified for the reverse position on a four-speed layout. The gear lever positions are as shown:

Three Speed	Four Speed
R 2	1 3
1 3	2 4

The gear positions should be clearly indicated on the gate or the base of the gearshift lever.

The hand brake lever should be pulled back to apply the brakes.

Spark and throttle levers should be so mounted that they do not turn with the steering wheel. They should be pushed forward to advance the spark or open the throttle.

The accelerator pedal should be placed to the right of the brake pedal. These recommendations will be put before the full standards committee at the meeting in October. They are based upon practice to some extent and also on what, in the opinion of the division members, is really best for easy manipulation.

Discuss Military Requirements

After the matter of controls had been settled there was a discussion of the military requirements. It transpired that the Quartermaster's, the Ordnance, En-

South America—IV

Three Months' Credit Necessary with Argentine Dealers—Longer Credits Not in Good Repute—Supply Depot Essential

By David Beecroft

THIS article is in sequence to that of last week. It is the tail end of it. Last week we analyzed the major considerations in connection with selling automobiles in South America, including the kind of cars needed, the selling seasons, and lastly came to the question of credits which formed the sixth consideration. Three months' credit will generally be necessary in South American sales.

We mention 3 months' credit because that is the figure generally fixed by many concerns. Three months allows for automobiles leaving your factory and being on the salesroom floor for 2 weeks or perhaps a month. The dealer in Argentina does not ask for anything more, he has reasons for asking for this.

He cannot possibly finance himself if he has to pay for his cars 2 months before he receives them, and particularly if they reach him at the end of the selling season instead of at the beginning. The dealer does not believe he is unreasonable in his 3 months' demands.

Many European countries gave much longer periods, 9 months, and some German credits extended for a year and as long as 15 and 18 months. It will not be necessary for any U. S. A. house to give such credit extensions. Argentina is not favorably disposed to such long credits. The good Argentine business man blames long credits for some of his recent troubles, and they blame those credits very largely for the crisis of 1911. So if you have heard that is is necessary to give credits of a year or longer, we believe that you can forget such and prepare for not over 90 days and you can cover yourself on these 90 days at as high as 8 per cent interest, in fact, that is what many of the older houses giving similar credits do.

Long Credits After War?

But you ask what will the credit terms after the war be. That is a question I am not prepared to even voice an opinion on. All through South America you hear comments of a widely varying nature as to what will happen when England, Germany, France and Italy get back into South America. You hear that Germany will come back with credits of a year or 15 months, but nobody has any assurance of such. You hear that England will give 9 months and France perhaps as long. Nobody knows. Many South American dealers wonder if it will be possible for these countries to extend such credits. That will depend to what extent they have been impoverished by the war. Depend on it that if these European countries can extend such credits they will not hesitate to do so.

England has been established in Argentine trade circles since 1862 when she opened her first banks there. Before the present war she had over $5,000,000,000 invested in Argentine railroads and other utilities and naturally she is not going to let that trade be plucked away from her for the sake of a few months' credit. Germany has her big business houses all through Argentina and Brazil and she, too, is going to come back with every drop of energy remaining. So with France, and Italy and Belgium and Switzerland. They have all had their fingers deep in the South American pie and are not going to let Uncle Sam run away with it very easily. Keep this sanely in mind when contemplating your future South American policy.

SEVENTH:—Be prepared to establish a good depot for spare parts in each of the South American countries where you hope to do business. Your good faith to stay permanently in the South American field will largely be measured by the faith you show in your invasion by backing up all cars sold with a liberal supply of spares of every part from engine crankcase to the smallest ball bearing. The South American buyer is keen on this spare parts program. He insists on it before he will purchase a machine. He knows that parts will break in the best of machines. He knows that he is 3 weeks by the fastest boat from New York. It is 3 weeks back. You may wait a week for the boat at each end. You may wait several days for the customs and then the repair or replacement has to be made. The car owner sees his car laid up for 2 whole months if there is not an adequate supply of spares for every model. A stock of spare parts is the greatest selling asset that any U. S. A. car has in Argentina, Brazil, Chile or any other South American country. If you lived in Buenos Aires or Santos, or Lima you would see it the same way. The distance you are in those lands from the factory terrifies you at times. The situation is so entirely different from anything in the U. S. A. that you can be pardoned for not having given the spare parts matter that mature consideration that you may have given all other factors in the deal.

With the supply of spare parts it is scarcely fair that the Buenos Aires dealer should carry the entire load. All of Argentina must be served. A better way is to establish your own depot for spare parts and put one of your own men in charge. That is what General Motors has done in Buenos Aires, and that was the reason why the organization got established early. Ford has done that all over. Studebaker is doing it. You must do it. One depot of this kind in Buenos Aires will serve for Chile, for Uruguay and for Paraguay. You will require a similiar depot in Rio which will serve for all Brazil. From such a depot or two it will be possible to sell the local agents a relatively small supply of replacements to meet exigencies. From these supply depots it will be possible to reach nearly any part of the territory in a few days.

Lesson from Tire Trade

Tires.—Just here take a page from the policy of the Michelin Tire Co. of France, which has had the great majority of the South American tire business until the war, since which time our U. S. A. companies and some of the Italian concerns have been cutting heavily into Michelin's trade. Take Brazil for example. Michelin has for years maintained a depot in Rio de Janeiro and another in Santos. In each he carries a very large supply of all sizes and types of pneumatic tires. He has paid the import duties on these tires and has his own organization looking after the depots.

What is the result of this system? The dealer in Sao Paulo in the coffee country can write out his order for any number of tires to-day and forward it with check to the Michelin depot in Santos. In two days the tires have arrived at his store. It is this two-day service that has built up the Michelin trade, and how can any of our firms hope to compete if they are not prepared to give something better than 2 months. A 2-month program of delivery will never compete against a 2-day program. Michelin dealers are always stocked up with tires and tubes and tire repairs. They do not object paying cash when they can get stock in 2 days.

EIGHTH:—It will be necessary for our automobile concerns to send some of their best men to South America to establish the business and to look after it until it gets well under way. Then you will have to put in permanently one of the best men you can get and he should be from your factory. A very large New York business house a few months ago decided to investigate the Argentina and Brazilian fields. It is in the printing business. The original intention was to send one of its best salesmen. Take a man from the road in the U. S. A. and put him in Argentina for a month and in Brazil for a similar period. Fortunately the board of directors saw that one of the best officers of the concern should go. This was done and with beneficial results. The same is being done with several other concerns, whose representatives we met while in Argentina and Brazil. Opening a business in South America is a big man's job. The fact that you can speak Spanish or Portuguese is not sufficient. You must know how business has to be done and is done.

You must also be prepared to keep one of your best men there. That is the way Ford did. Studebaker is following the same plan. Many others will have to do so. Singer Sewing Machine company did this. The National City Bank of New York has U. S. A. managers in every branch and several of the department heads are also from the U. S. A. So it is with the United Steel Products Co., so it is with our express companies, so it is with the International Harvester Co., so it is with Armour, Swift and the other large packing interests, so it is with the J. I. Case Co. and so it is with every other strong U. S. A. concern that has got in strong in South America. They went there to stick and they are sticking and doing well. The head men of the West Indian Oil Co., which is the Standard Oil Co., has its U. S. A. men in charge.

Have U. S. A. Staff

This policy of manning the South American business with home men is not anything that Uncle Sam has a patent on. England does the same, and so does Germany, France, Italy, etc. But England and Germany go much further. Generally England sends an entire office force. The manager will always have his stenographer from England and if one leaves he immediately cables the home office in London for another. This is because it is hard to get good men stenographers in many South American cities, and if you have not a good stenographer it means that the manager may have to write many of his own letters to the home office. This is actually being done by many of our concerns. I have seen many men, managers in a large territory, who were writing their own letters on typewriters, simply because they could not get satisfactory help. It was pathetic to see a man whose time was worth $200 a week doing work that a $30 clerk should have been engaged to do.

England and Germany have both profited on this score and have counted the value of sending a good quota of office help. Male help only should be sent. You can get much competent office help but you must have your own manager, preferably your own department heads, and also a few good clerks to take much of the load off the manager and others high up so as to conserve their energies for developing the business. They have been sent down for development work and you must not make clerks of them.

These men should go prepared to stay for 5 or 10 years. They should go to remain permanently. In Buenos Aires the U. S. Steel man has been there for 10 years. Some of the head men of the Singer Sewing Machine Co. have been there for nearly 15 years. The same is true with regard to Standard Oil. You can say the same of many other companies. The South American does not like changes in his business relationships with foreign countries. It is hard enough to do business with the U. S. A. even if the same man remains head, but how much harder is it if the Argentine merchant has to get acquainted with a new manager every year or so. There is nothing so detrimental to good Argentine or Brazilian business as frequent changes in management. Consequently you must pick your men carefully and they should have in mind a residence of several years in South America.

Living in South America is not so pleasant as in the U. S. A. but it is not nearly so bad as it was 4 or 5 years ago. Conditions are changing very rapidly. It is much easier on men than on women. Woman's life in Argentina and Brazil cannot be compared with that in the U. S. A. and so they tire very soon of life there. The men get on immeasurably better, but so often they are always living for the day the steamer sails and then hope never to have to go back; it is well known that a few of our older and larger business houses not in the automobile industry have stopped sending married men as managers to South America. They send experienced young bachelors who generally get married a few years afterward to native Argentines, Brazilians or Chileans, as the case may be. They become good citizens and are very contented.

Living Expenses High

NINTH: Be prepared to stand the expense of establishing a business in South America. This expense is greater than you to-day imagine. It is more expensive living in Buenos Aires than in New York City. It is expensive traveling in all parts of South America. On the return trip the representative of the Singer Sewing Machine Co., who has been in charge of the South American and Latin-American business of the company, said that it was the experience of their concern that young men had to be paid considerably more for living and traveling expenses in Argentina, Brazil, Chile and other South American countries than in the U. S. A. Others who have had years of experience in older lines of merchandise have learned this lesson.

In Argentina and Brazil you hear of many representatives of U. S. A. automobile concerns running short of funds, not having been given sufficient traveling money. Three or four specific instances came up during the months of May and June. In general it requires about $20 per day U. S. money to care for a representative who has considerable traveling and who must do a limited amount of dinner entertainment. The manufacturer who sends his representative down on a too scant allowance is proportionately reducing that representative's ability.

Railroad traveling is expensive, and there are a score of other expenses that have to be met, which frequently do not enter into business in the U. S. A. We know of one case where a maker objected to an item of charges for carrying baggage on the railroads in Brazil because he compared the rates with those in America and imagined that his representative was attempting to pad his expense list. To carry a small trunk with you on a railroad in Brazil costs nearly as much as your own railroad ticket. For a steamer trunk you will pay as high as $5 U. S. gold for a night trip such as Chicago to Buffalo. You will pay $3 to $4 for a bed per night on the railroads and often double of this amount. These are conditions that must be considered. Get it out of your head that South America is a cheap country to live in. It is not. It is not a cheap country to do business in.

Typical Argentine carts with capacity for 6 to 10 tons on a highway leading to a depot. These carts are the lords of the highway and with their 62-in. treads dictate what tread the automobile for the Argentine must have. In bad roads as many as thirty-five horses are hitched to one and the speed is not over 2 miles per hour. Note the great width of Argentine roads, which in some cases are as wide as a field. In rainy weather these carts are tremendous loads to draw

Attractive Homes for South America's Motor Agencies

1—*The Cadillac agency in Buenos Aires owned by Fehling Hnos, or Fehling brothers. This firm has had the Cadillac agency for nearly 14 years*

2—*The Cadillac agency in Cordoba, a city a night's ride by train from Buenos Aires and situated near a short range of mountains. This section has the best roads of any part of Argentine due to a good supply of gravel. There are five or six excellent gravel roads radiating from the city and piercing the mountain sections*

3—*Bosch magneto headquarters in Buenos Aires. This house is located in the best section of the city and on the leading motor thoroughfare*

4—*This is a large Buenos Aires garage, and while the exterior is plain plaster, the interior is well laid out. This garage has two entrances, the garage being divided centrally into equal halves*

5—*Buenos Aires is well acquainted with various devices to accelerate loading and unloading. Here is shown a power conveyer loading sacks of grain, each sack weighing 132 lb. The bags are carried direct from the warehouse to the hatches*

This is the famous immigration department in Buenos Aires, which is considered the best in the Americas. Note the wide, well-paved streets. This is a characteristic of South American cities. They have given good areas for railway depots, steamboat wharves and freight terminals. This makes these cities ideal for motor car and motor truck uses. Add to this the fact that power loading devices are very widely used and two or three obstacles to truck use are overcome

Buildings Reflect Atmosphere of Industry in South America

6—*Exterior of a new Buenos Aires garage located in a residential section of the city and intended solely for passenger cars. This garage uses a ramp instead of an elevator*

7—*Here is another example of modern power cranes being used for loading and unloading and the general handling of merchandise in Buenos Aires. Each wharf is lined with power cranes for lifting loads off railroad cars*

8—*This is the interior of the second floor of the garage shown in Fig. 9. The exit from the ramp is in the center just in advance of the wire fencing. The garage is typical of the latest construction in Buenos Aires and has steel construction throughout*

9—*Showing ramp for second floor of garage, Fig. 8. This ramp is so located as not to interfere with cars stored on the main floor, in that it has a separate entrance with room for running a car from the main floor up the ramp without having to drive it outside of the garage.*

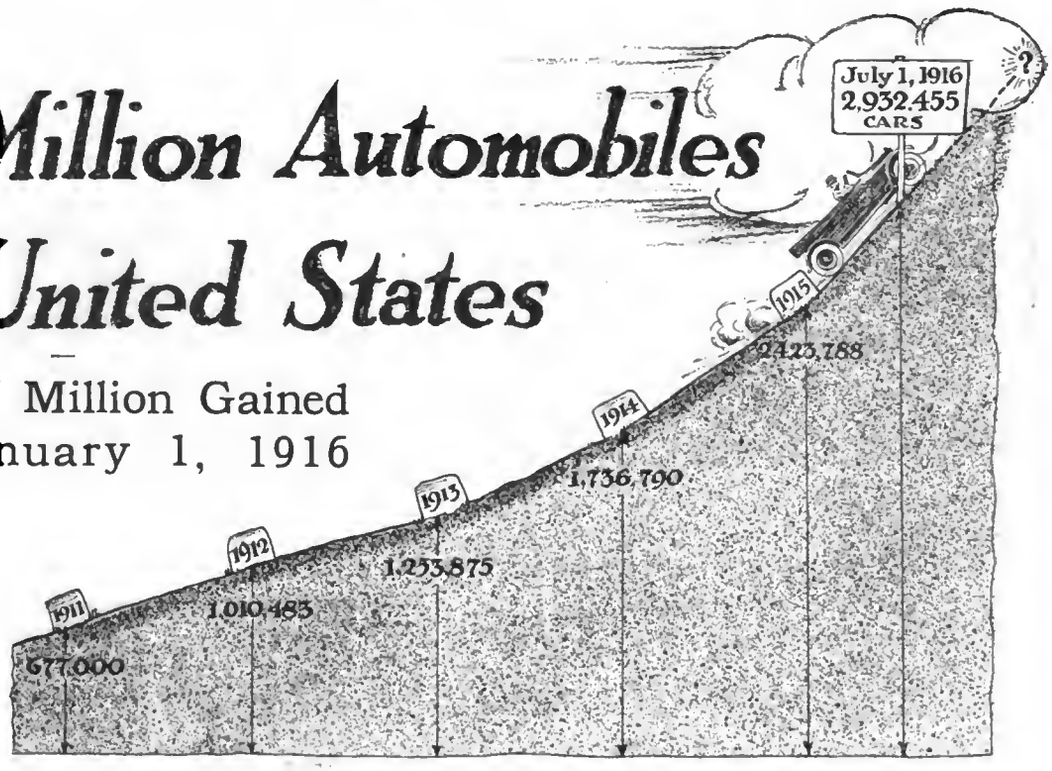
10—*Interior of large taxicab garage in Buenos Aires, operating 300 cabs. In the rear is a complete repair department and the organization of this garage is a model of its kind.*

Three Million Automobiles in United States

Over Half Million Gained Since January 1, 1916

By Donald McLeod Lay

THERE are 508,677 more cars in use to-day than there were on Jan. 1, 1916. There are over 3,000,000 automobiles in use in the United States to-day, including both passenger cars and trucks. Between Jan. 1 and June 30, 1916, the increase which had taken place was not far short of the total increase for the whole year of 1915. There are now three States having over 200,000 cars apiece, New York, Ohio and Illinois, whereas on Jan. 1 of this year only New York had as many as this. Eleven States have over 100,000 machines each, Minnesota, Massachusetts, Indiana and Texas having passed into this class since Jan. 1.



Registration Hill is constantly growing steeper as the rate of increase climbs

At the present time there is one car to every thirty-five persons in the United States

In thinking of these big figures it must not be forgotten that the industry has been producing a good many more cars than those absorbed in the United States. Since Jan. 1 the exports have totaled 43,265.

Taking up a few exact figures, the total registrations July 1, 1916 were 2,932,455 cars and trucks. The largest State registration, that of New York was 259,105. Ohio, taking second place for the first time, had 208,705 and Illinois 203,757. New York now holds the place at the head of the list by a margin of 50,400 registrations. The bottom of the list is occupied by Nevada with 3900 cars but Nevada ranks fourteenth in the tabulation showing the number of people per car, New York taking the twenty-eighth place in this list.

Iowa has a motor vehicle now for each 13 people, California one to each 15 people and Nebraska one to each 16, while New York has as many as 39 inhabitants to every car.

A striking feature brought out by a comparison of the registration statistics of July 1 and those recorded at the first of the year is the constant increase which indicates the stability and normal progress of the automobile industry. The average increase in registration in the United States for the entire year of 1915 was 39.6 per cent; for 6 months of 1916 the average is 21 per cent, or approximately 40 per cent on a yearly basis, since the registration tapers off to some extent during the last 6 months of the year.

A study of the tables herewith, both the complete registration figures for each State and the statistics of gain in each, brings out the underlying economic factors which have made a registration of 3,000,000 automobiles and trucks possible in the United States to-day. Prosperity has been the rule throughout most sections of the country and the sale of cars naturally follows the spread of prosperity. A glance at the tabulation of States showing the increase in registration suffices to bring out that those which have made the largest gains are the ones most affected by the unusual industrial conditions prevailing in this country since the outbreak of the European war. New York, the leading State, represents

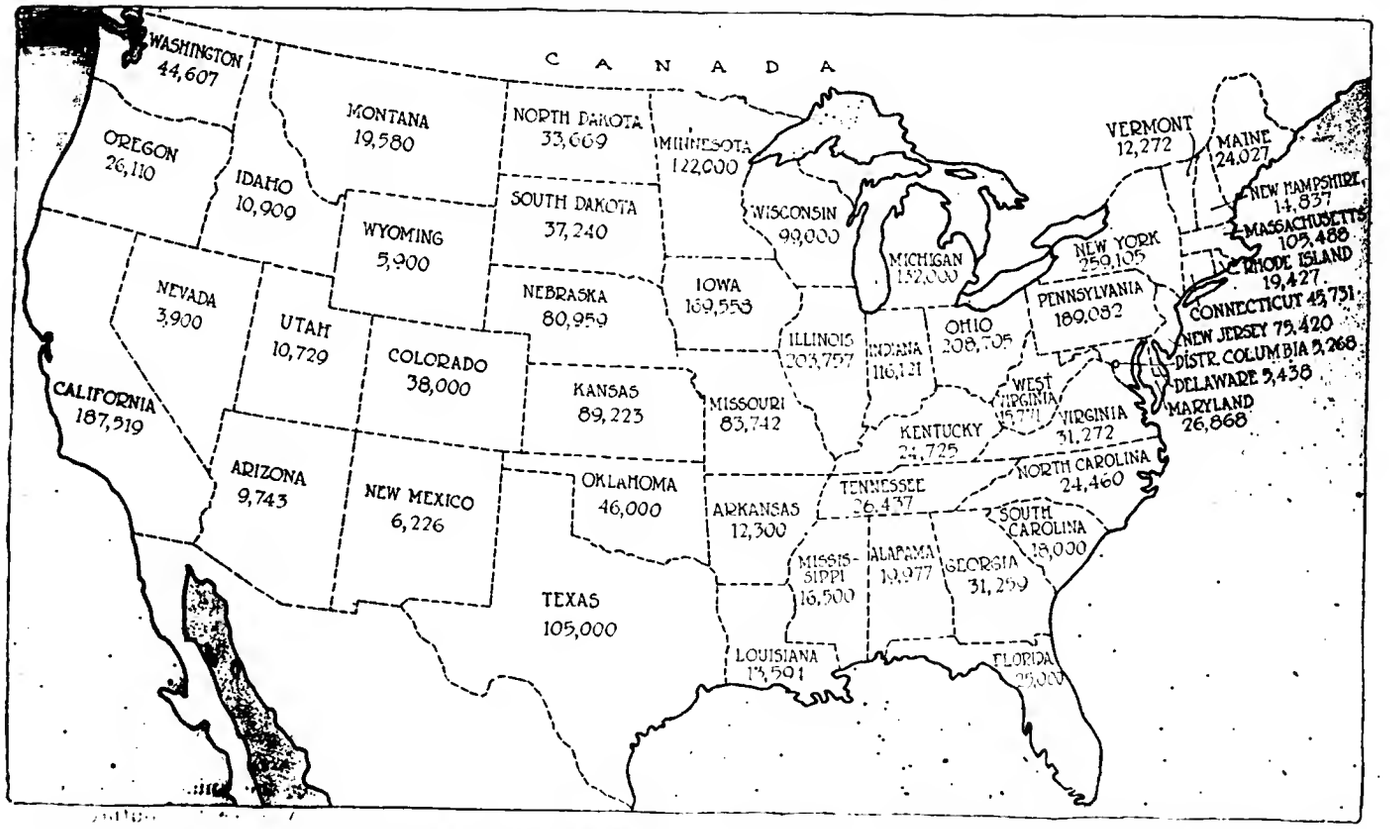
NOTE.—Steam cars and trucks included in gasoline vehicle statistics as well as electric vehicles where these are not segregated. *Number of cars registered owned by citizens of other States **Number of cars re-registered, owing to transfer of ownership, etc. ***Not listed separately by registration officials. †Estimated by State registration officials. ††Estimated by Dallas Automobile Club. §Registration low due to new law. §§Registration not required.



Map showing the number of cars registered in each State. The tabulation above gives this information with other interesting data

in large degree the enormous financial operations connected with the war order business throughout the country as well as the huge profits derived from the reorganization of capital and securities in foreign countries. Its normal growth has been accelerated by the increase in the foreign commerce of the United States, the bulk of which is transacted through New York City.

Pennsylvania, which stands second in growth of registration with a gain of 38,353 cars and trucks, has shared in almost every form of industrial boom that has taken place, utilizing the high prices of the commodities which it produces in such large volume. The price of steel has been steadily going up and Pennsylvania is one of the largest producers. The price of coal is higher and Pennsylvania is one of the leading States in coal mining; agricultural products are selling for higher prices than ever before and Pennsylvania's contribution to this field of industry is enormous; and last, but not least, there has been an unprecedented boom in the oil industry, which also has redounded to the profit of the Keystone State.

Population to car ratio in each of the United States shown graphically

Minnesota next in line with an increase of 30,171 registrations is one of our largest agricultural and lumber States so that its 33 per cent gain is largely due to the wide market and highest prices for these products.

Iowa, another big farming State has been steadily forging toward the front rank in motor vehicle registrations for the past 5 years and during the first 6 months of 1916 shows an increase of 29,750, or more than the entire number of registrations at the end of 1911 when the State boasted of 27,936 automobiles.

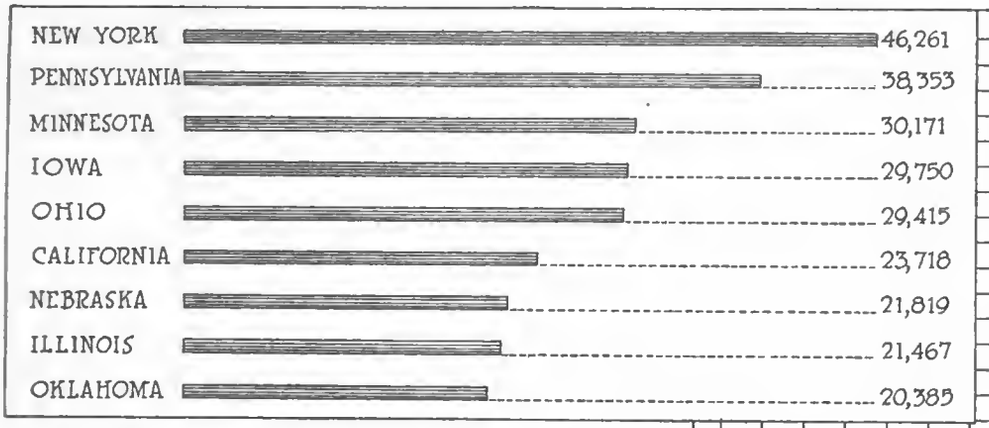
Ohio, with its big oil fields, its large manufacturing industries and extensive farming interests, has increased its registration 29,415, or 16 per cent, and without question a large part of this gain is directly attributable to the prosperity marking the State during the past 6 months.

Some of the other States which may be mentioned in this connection are Nebraska, a leading agricultural center, which is credited with an increase of 37 per cent over its 1915 registration; Oklahoma, which has an apparent increase of 20,385 cars or 80 per cent, a large part of which is due to the boom in the oil industry, although it must be noted that, it is only recently that registaration has bas enforced, so that the statistics recorded Jan. 1 were really incomplete.

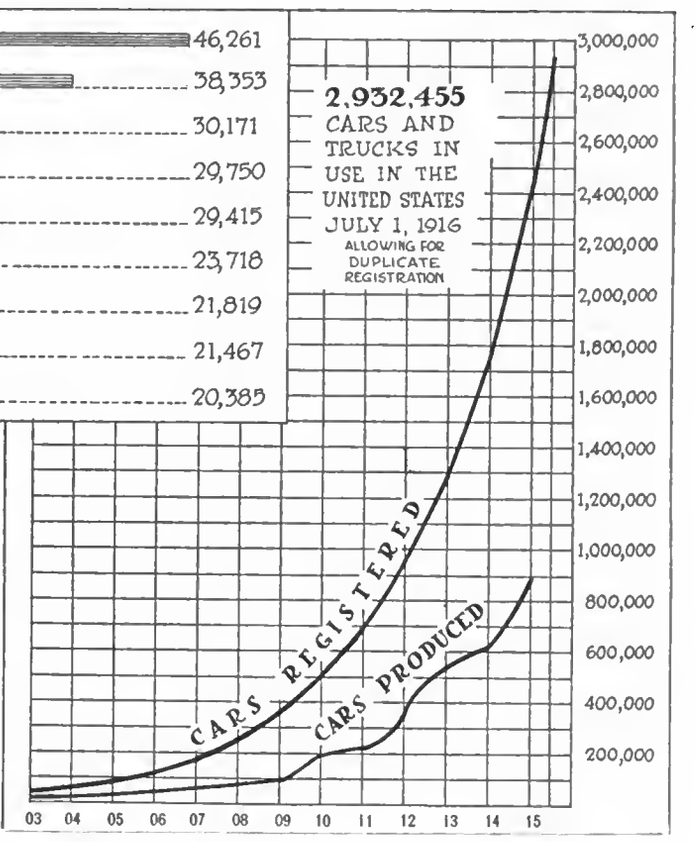
A similar condition may be noted in New Hampshire which shows an increase of 37 per cent during the 6 months. This State is a big center for tourists and summer residents and it is undoubtedly due in a large measure to this fact that the gain has been so marked.

In Florida, there has been a gain of 11,877, or 90 per cent, part of which represents cars previously unregistered, but the bulk of the gain may be attributed to prosperous conditions in the lumber business and other leading industries of the State. Lumber and agriculture also had much to do with the increase of 7702 made in Washington, while high metal prices combined with farm activities to give Missouri 7280 more cars than were registered in that State at the beginning of the year.

War orders and their consequent profits are responsible for some part



Nine States which increased by more than 20,000 during the last 6 months



of the 17 per cent expansion of Connecticut registrations, and high prices for cotton and lumber contributed to Georgia's 30 per cent gain. Louisiana shows a gain of 25 per cent due to high sugar prices and the big cotton market. Arizona's copper mining industry played its part in giving that State an increase of 33 per cent.

Several of the States which formerly constituted the tail-end of the list have shown larger gains than others which formerly led them. Nevada, which was last on Jan. 1 has moved up three places, similarly Wyoming, which was second, has moved upward in the same degree as Nevada and several other similar alterations of position have taken place.

On a basis of ratio of cars and trucks to population Iowa's lead, with thirteen people for each motor vehicle, compares with sixteen people per car at the beginning of the year. California is still in second place in this respect, having increased its ratio from eighteen people per car to one car for every fifteen of its population. Nebraska continues third but it has now made a signal gain, showing only sixteen people for every motor vehicle as compared with twenty-one people per car on Jan. 1. Indiana is now fourth, having come up from ninth place by increasing its car-to-population ratio from twenty-nine to seventeen. Indiana has thus displaced South Dakota which was formerly fourth, but is now fifth, showing a decrease of five people to every car. Min-

nesota has passed Kansas, having nineteen people per car as compared with twenty-five on Jan. 1, Kansas being now in seventh place in this respect with twenty people per car as against twenty-four at the beginning of the year. All the rest of the States have over twenty people per car, beginning with North Dakota which has twenty-two and ending with Arkansas which has 144. It will be noted that practically all the States at the bottom of the table comparing population and cars, are in the South, and the large number of people per car in these States is due to the large impecunious negro element in their population.

The statistics in the tabulation appearing on page 263 are all furnished by the registration officials of the various States, with the exception of Texas where such figures are not available because of local registration. In this case several estimates were furnished by various interests in the State and that of the Dallas Automobile Club was accepted as it agreed with several of the others and because it was the most conservative. It is very probable, however, that there were 110,000 cars and trucks in use in the Lone Star State on July 1, instead of the 105,000 with which it is credited. In the District of Columbia a large non-resident element had to be deducted, as will be seen by reference to this table, and comparison with the statistics in the tabulation on page 262. Since registrations in the District are perennial it is possible that the total number of cars and trucks actually in use by the 361,330 residents is somewhat in excess of the 5268 given. Other points worthy of mention are the apparent decreases in Maryland and Tennessee. These States have new laws in effect and registration under these new laws has not been completed. Colorado and Oklahoma are other States with new laws but these have been in effect long enough to enable the bulk of the registrations to be completed and an accurate line to be drawn on the number of cars.

It is worth mentioning that the fees received by the various States for the registration of automobiles and motor trucks for the first 6 months of the year totaled $14,261,112.72, this including the revenue from only thirty of the forty-eight States and of the District of Columbia. It is certain that if information were available as to the fees taken in by the other States the total would be well over $15,000,000.

The number of automobile factories and their distribution by States may be seen in the tabulation on page 265. On the same page appears a complete table of statistics showing the distribution of dealers, garages, repair shops, supply houses and charging stations in each State up to July 1. Both these tables have been compiled by the Automobile Trade Directory.

Rhode Island Registrations Analyzed by Makes

OF the 19,427 automobiles and motor trucks registered in Rhode Island up to July 1, there were 15,402 gasoline passenger cars bearing the names of American manufacturers, 226 machines of the same class which represent European factories, and 193 electric passenger cars. A total of 3576 commercial vehicles were registered of which 3522 were gasoline machines and fifty-four were electrics. The large number of European cars in use in Rhode Island is due to the large summer population of New York and Philadelphia people at such summer resorts as Newport, Westerly and Narragansett Pier. During the first 6 months of 1916 there was an increase of 3065 automobiles and trucks as compared with the registration on Jan. 1, 1916. This is at the rate of 19 per cent which is about the normal increase in States not affected by such unusual prosperity as resulted from war orders, bumper crops at high prices, or booms such as that in the oil industry. It is a continuation of the rate of increase of the past few years.

Securing Even Power in Cylinders

Pulsations in Intake Manifold Can Cause Variations in Mean Effective Pressure in Different Cylinders of the Same Engine—Tests Show Effect of Alteration in Order of Firing

By Robert Antony

THE recent development of engine design in America has been confined, to a great extent, to the increased production of power from cylinders of smaller dimensions than have been common practice in years past. Such developments have been accompanied by improvements in the quality of the materials used for reciprocating parts and a re-arrangement and re-design of moving parts generally, while certain other details appear in many cases to nave been either overlooked or regarded as of secondary importance. The trend toward multi-cylinder development and the adoption of a single carbureter for the supply of a large number of cylinders has, in a measure, eased some of the carburetion problems, when considered from the point of view of the carbureter as a single unit.

Induction Impulses Important

Even many men who are fully alive to the technical points in connection with the carburetion problem appear to overlook the fact that carburetion is seldom complete, nor in any event can it be considered so that the moment the working mixture leaves the main orifice of the carbureter. To give a single example, when the present writer suggested that induction pipe pulsations were a matter of considerable interest, the response he drew was to the effect that the general adoption of multi-cylinder engines had practically quashed all problems arising from vibrations of this nature, and that the matter therefore was not of great general interest. Such a statement is entirely erroneous, and if one considers for a moment any system of induction on any engine, whether of four, six, eight or twelve cylinders, it must be perfectly obvious that insofar as each individual cylinder is concerned, some interference must be felt by reason of the operations of other pistons, valves, and pipe arrangements in the complete unit.

From the earliest days one of the difficulties experienced, both by the maker and the user of a gasoline motor, has been that of producing an approximately equal power output from each of the cylinders in the engine. Perhaps this difficulty was more pronounced in the early days by reason of the very crude methods of effecting carburetion, by the meager mechanical action upon the fuel and by the lack of a streamline formation of the passages and ports in the induction system. All these things tended to aggravate an initial evil.

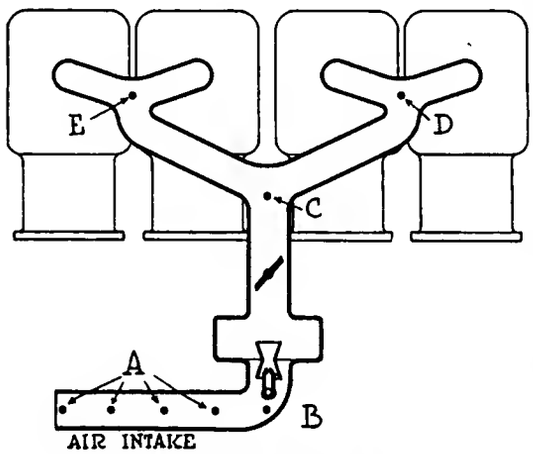

Fig. 1—Points at which readings were taken indicated diagramatically

Variations in Gas Pressure

In any system of pipe arrangement where numerous orifices are supplied from one central source, there must be variations in gas pressure at various points of the system. The endeavor of the designer has been to arrange an equal length of pipe from the carbureter orifice to the valve pockets of all the various cylinders comprising a single power unit. It must be remembered, however, that it is not only the length of the pipe which influences the fluid resistance it exerts, but also the contour and the departure from a straight or streamline form. The frictional resistance of a right angle bend to the flow of a liquid is approximately equal to that of 50 ft. of straight pipe, but in the case of air carrying a liquid in suspension we have the aggravated evil of turbulence setting up precipitation of the liquid in the containing receptacle.

If we had a power unit whose demand for fuel was continuous and uniform, such as, for example, an internal combustion turbine, this article would not have been written. On the contrary, our unit at the present time, although tending in that direction from the point of view of the main intake orifice, is very different when considered from various locations in the distributing system for the working fluid (the term working fluid is here used in the scientific sense and means the air mixed with its correct proportion of hydrocarbons).

In order that the reader may have a graphical idea of

Fig. 2—Variation at point C at one-eighth full power.

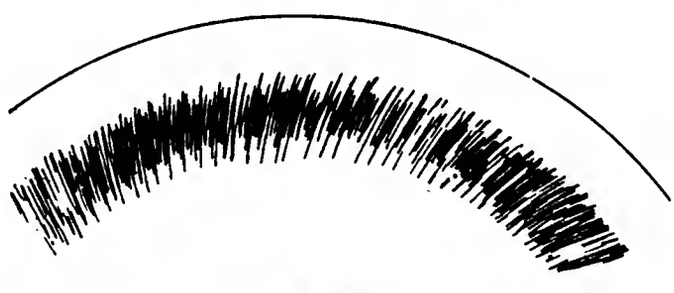

Fig. 3—Effect of increasing speed above that of Fig. 2

what is occurring in an induction system the diagrams here reproduced have been prepared and are direct copies of a few taken from a large series made directly by a suitable instrument connected to an induction system. With the engine in question, observations of pressure variation were made at the following points in the system:

A—At the carbureter inlet.

B—At various positions within the carbureter, between the inlet and the choke tube.

C—At the junction of branch pipe above the throttle.

D—At the junction of two pipes feeding two cylinders in succession.

E—At the junction of two similar pipes in another part of the system.

The accompanying diagrams are made by the pen traveling in a counter-clockwise direction across the paper; that is to say, the chart is moved in a clockwise direction, the pen itself being stationary in the instrument. Their purpose is, primarily, to show the relative pressures at the two positions indicated and also the relative intensities and contours of the graphical reproductions. By reason of the length of the connecting pipe between the engine and the instrument, there is a certain amount of damping of the magnitude of the oscillations as indicated, and this must be borne in mind.

The diagrams are made to a scale which reads from atmospheric pressure at one end to a vacuum of 30 in. of mercury at the other end, and in order that clear diagrams could be obtained, a slow speed engine of large linear dimensions was used.

It must not be concluded that these diagrams do not apply to other types of engines by reason of the difference in conditions, as the physical facts are the same whether the engine be large or small.

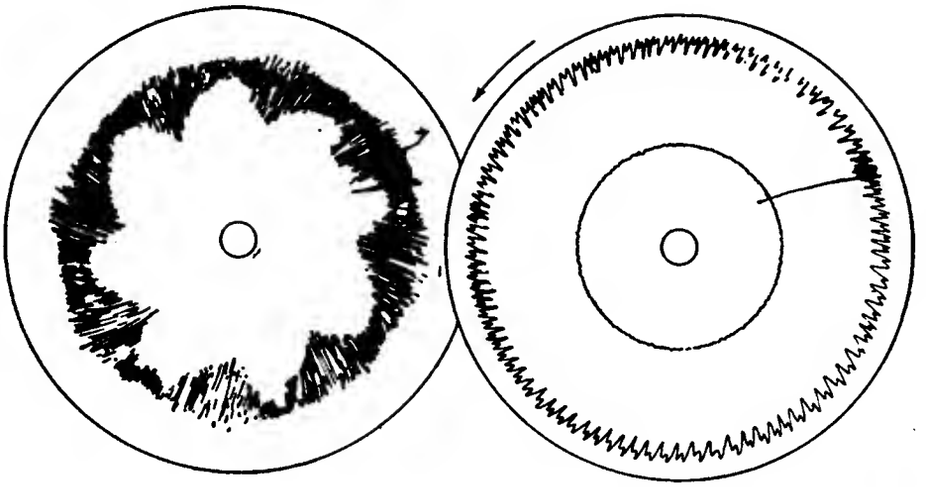

Fig. 4—Effect of fuel loading in the manifold. Fig. 5—Diagram resulting on adjusting carbureter to prevent loading

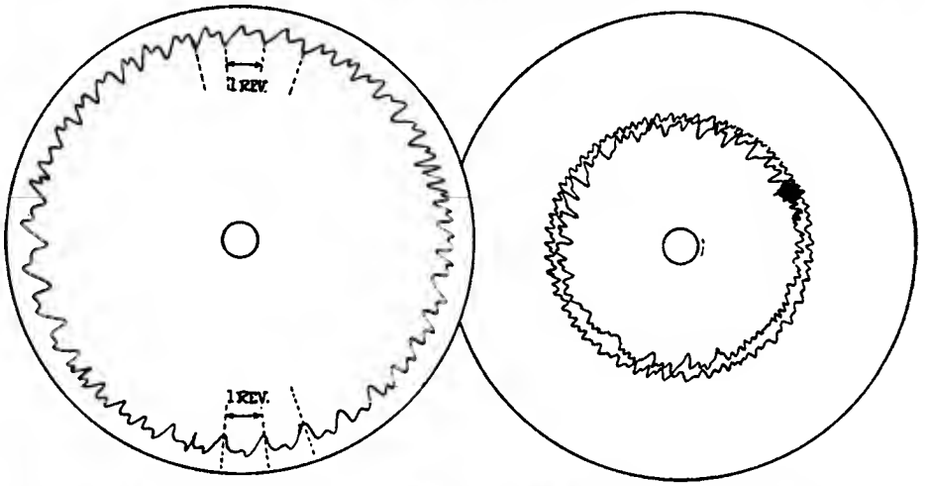

Left—Analysis of Fig. 5 to larger scale. Right—Fig. 6—Effect of inertia of air stream

Under Different Load Conditions

Fig. 2 shows the variation in pressure at point *C* when the engine was developing about one-eighth of its maximum rated power, and it shows that the negative pressure was from 15 to 21 in. of mercury. At 15 in. the engine throttle was evidently controlling the flow of the working fluid very uniformly, and as each valve opened in turn the pressure in the pipe dropped to approximately the same point. The diagram was taken for the duration of 1 minute, and there is practically no sign of accumulation of liquid fuel causing the engine to hunt.

We will now examine Fig. 3, which shows the state of affairs at point *C* when both the load and the speed had been increased, and we begin to find marked interference, as instead of the pressure returning to 15 in. at the end of each impulse the maximum pressure of minus 10 in. of mercury is only reached once in approximately four oscillations. The minimum pressure of 14½ in. is likewise touched, while in the intermediate stages the pulsations are confined within smaller limits.

Fig. 4 shows the effect of the fuel loading in the pipe, due principally to faulty carburetion. This diagram was taken over a period of 1 minute and the effect of hunting is clearly shown. In this case the maximum negative pressure is minus 2 in. of mercury and the minimum is minus 7 in. The hunting here occurs in regular sequence and is undoubtedly due to accumulations of liquid fuel forming in the pipe and being carried away periodically by the incoming air.

Effect of Adjustment

Under improved adjustment of the carbureter, Fig. 5 was taken, the horsepower output of the engine being approximately one-half its maximum, and in order to give clearness to the diagrams this and subsequent ones were taken over shorter periods, Fig. 5 being for a duration of a quarter of a minute. The inner diagram, showing a wavy line at a negative pressure of ¾ in. of mercury, shows the observation at the air intake, point *A*, of a Schebler carbureter. The outer diagram was taken at point *C* and each complete oscillation occurs during one cycle of the engine, and as four cylinders were fed in this period, the pressure at the junction of the manifold shows that at the moment of valve opening the pressure in the pipe is approximately minus 7½ in. of mercury in one instance, and minus 8¾ in. when the second valve opens in each revolution. It will also be noticed that the intensity of the suction varies slightly, even under such comparatively light loading. Under such conditions, however, the inertia of the air column is scarcely manifest as this comes into play at higher speeds. It may, here, be well to note that it is the effect of the inertia of the air column that has to be taken into account in the consideration or design of an induction system. The motive power of the air stream is the atmospheric pressure, and this being com-

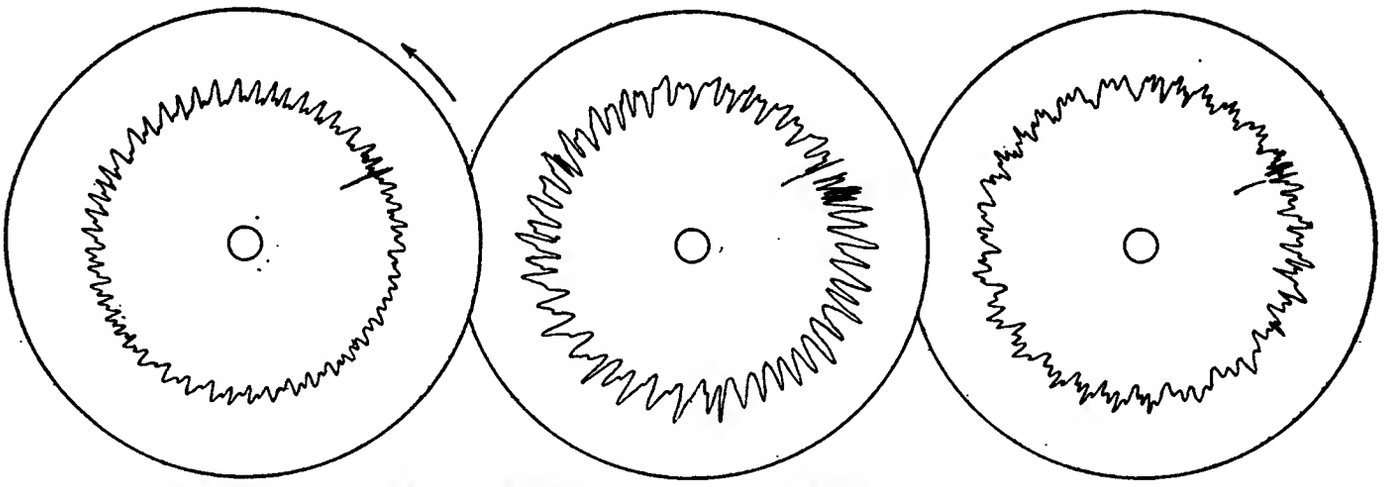

Fig. 7—Closer analysis of Fig. 6. Figs. 8 and 9 taken at points D and E show variations in similar positions in manifold

paratively low as considered in relation to other pressures in an automobile engine, the best advantage must be taken of it in order to obtain a uniform distribution. When the air stream is once put into motion it should be so timed and directed that its energy is expended usefully rather than as an interfering agent, as will be seen in subsequent diagrams.

Fig. 6 shows where the inertia of the air stream begins to take effect. The inner diagram is a record of the pulsations at the point *C*, being the junction of the branch pipe, the outer was taken at a point adjacent to the choke tube of the carbureter. We now begin to see how the pressures in the induction pipe at the times of opening of the various inlet valves vary, and we further notice the influence of sequences of valve closing upon the pressure waves in the pipe.

Periodicity Every Two Revolutions

There is a marked periodicity recurring every two revolutions of the crankshaft and a further smaller intermediate period after two valves have closed in sequence in one location of the induction system. The fact will be observed that the minimum pressure at the point *C* approximately corresponds with the maximum pressure at the point *A*. Fig. 6 is an observation during 6 sec.

When we proceed to analyze Fig. 6 in greater detail, we obtain Fig. 7, which is taken under practically the same conditions as Fig. 6, and which records the summation of the vibrations shown in Figs. 8 and 9, each of which occurs at opposite ends of the pipe at the points termed *D* and *E*. Now one would be led to expect that Figs. 8 and 9 would be similar, in view of the fact that they are taken from mechanically similar positions, the valves are timed and arranged alike, and the relative sequence of operations is the same. Yet, not only are the diagrams dissimilar from each other, but each one in itself is not of very uniform shape. Some allowance must be made for the fact that the charts were rotated by hand, which would cause some error in the lateral dimension of the graph, but the longitudinal dimension also varies from moment to moment. This may possibly be due to the inertia of the valves and their operating mechanism, but the figures are here shown to indicate how the action of the gas may vary. Later tests enabled more uniform graphs to be produced.

It must be noted that in these diagrams the throttle was held fully open and one is therefore able to arrive at some indication of the possible volumetric efficiency of the engine, as the negative pressure adjacent to the valve pockets varied from 1½ to 4 in. of mercury in Fig. 8, and 1½ to 3¾ in Fig. 9.

Fig. 10 is given to show the effect of opening the throttle

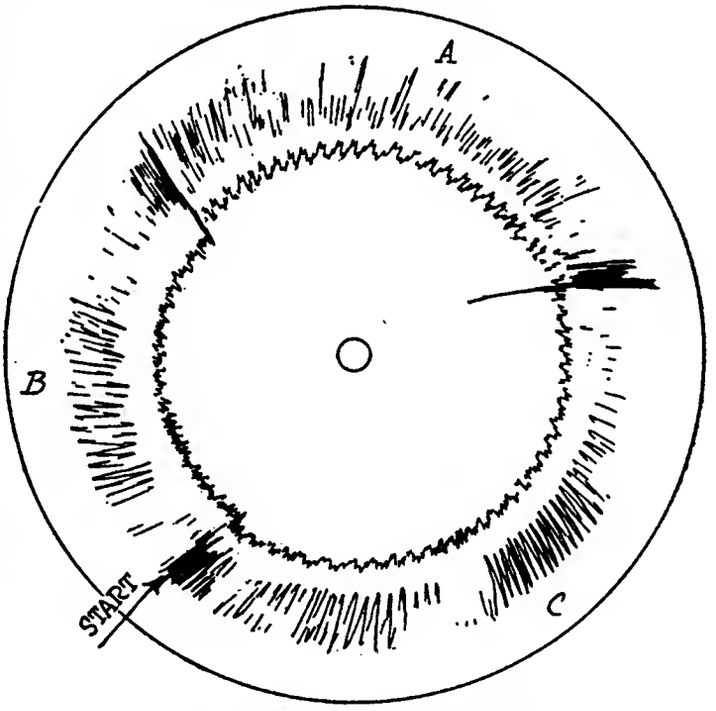

Fig. 10—Effect of opening throttle

under conditions corresponding to those obtained in ordinary road working. This graph taxed the powers of the instrument rather severely, so that its detail is not very clear. It will be noted that it is divided into three segments, *A* corresponding to point *C* on the pipe, and *B* and *C* to points *D* and *E* respectively. The graph was started with the engine running at half its normal speed and load, and the three observations made. The speed was then increased by opening the throttle, but the load was not increased to its maximum, but only to three-fourths of that amount. It will here be seen that at the junction of the induction pipe the negative pressure was an average of 5½ in. to 6 in. of mercury.

Fig. 11 shows a similar set of observations when the maximum load was carried, and in this instance the negative pressure at point *C* varied between 2 and 3 in. Attention must be called here to the interference which is shown in Section *B*, which is taken at point *C* on the manifold and which is indicated by the small loop at the point of maximum pressure when the engine is running at the lower speed. As the speed increases this loop becomes proportionately greater, showing the effect of the inertia increasing with the gas speed.

At this stage another engine was taken, with the sequence of firing reversed as compared with the previous engine; that is to say, that the two valves in any one pocket operated in the reverse order, and the comparison shown between the previous graphs and those of Fig. 12 and the immediate subsequent ones gives the following results:

Pressure Drops on Aspiration

Considering Section *A* taken at point *D*, we notice that in the new arrangement the point of minimum pressure was reached after the second aspiration as contrasted to the third in the previous engine. It will also be seen that the first aspiration reduces the pressure to half the total amplitude, whereas in the previous engine the first aspiration only gave a drop of insignificant proportions. In this engine we find that after the second aspiration there is a rise of pressure of 1 in. of mercury, whereas in engine No. 1 the rise in pressure after the second aspiration is of the order of a quarter of an inch. Engine No. 2 lowers the pressure at the third valve opening an amount of about half an inch of mercury, whereas Engine No. 1 lowers the pressure nearly an inch at the same time. Considering now point *E* shown under Sec. *C* we find that in the new engine the maximum drop of pressure occurs after No. 1 valve has opened; that is, reckoning from the point of maximum pressure in the pipe and from this time each valve opening in turn reduces the pressure an imperceptible amount, that is to say, that after No. 2 valve has opened the pressure is not so low as it was after No. 1 valve had functioned. From this time onward the pressure at the point of observation gradually rises. This shows that after the two valves situated in the location of point *E* have operated, the functioning of other valves in the system has practically no effect upon this part of the pipe so far as pulsations are concerned.

In the previous engine, however, a different state of affairs occurred, which is somewhat difficult to explain. It was discovered, for example, that after the first valve has opened the pressure drops to only half the full extent of its amplitude. The second valve opening increases this somewhat further, but not until the third valve in the system has opened do we find the minimum pressure at point *E*. The fourth valve scarcely affects the contour of the pressure curve.

Comparing again the diagrams Figs. 11 and 13, it is interesting to note that the small kick at the end of the swing of the pen occurs at the inner end or higher pressure point in Engine No. 1, whereas it occurs at the lower pressure point in Engine No. 2.

Referring again to Fig. 13, it is instructive to note that the reversal of the valve closing sequence has brought segments *A* and *C* more nearly alike than was previously the case, the amplitude of the pressure swing in either pocket varying from 1½ to 3 in. of mercury; at the junction of the pipe from 1 to 2 in., and at the carbureter inlet it is an average of 1 in. of mercury, the carbureter in this case being a Master.

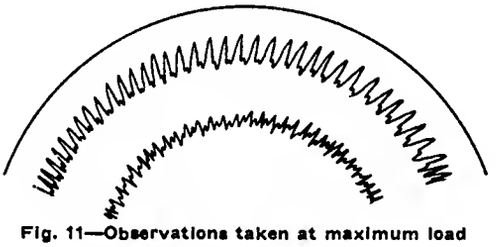

Fig. 11—Observations taken at maximum load

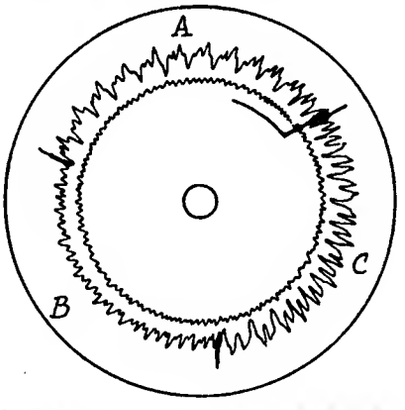

Fig. 12—Effect of reversing the sequence of firing

Pulsations Not Uniform

Figs. 14 and 15 show a similar series of observations upon a more open scale and with a Schebler carbureter in use. In this and subsequent observations, the recording instrument was brought nearer to the engine, thus eliminating some of the damping effect of the connecting pipe. The engine in this case was working under full load and the observed drop of pressure at the carbureter inlet is 2 in. of mercury. It will be noticed that the pulsations at the inlet are not at all uniform and this may be accounted for by the action of the extra air valve. The Master carbureter in Fig. 13 under practically the same engine conditions shows a drop of pressure of only 1 in. at the carbureter inlet and a much more uniform curve at that point. Section *B* in Fig. 14 again shows considerable lack of uniformity, much more so than when the Master carbureter was in operation, and this again may be due to the operation of the air valve.

Fig. 16 is instructive as showing the effect of replacing

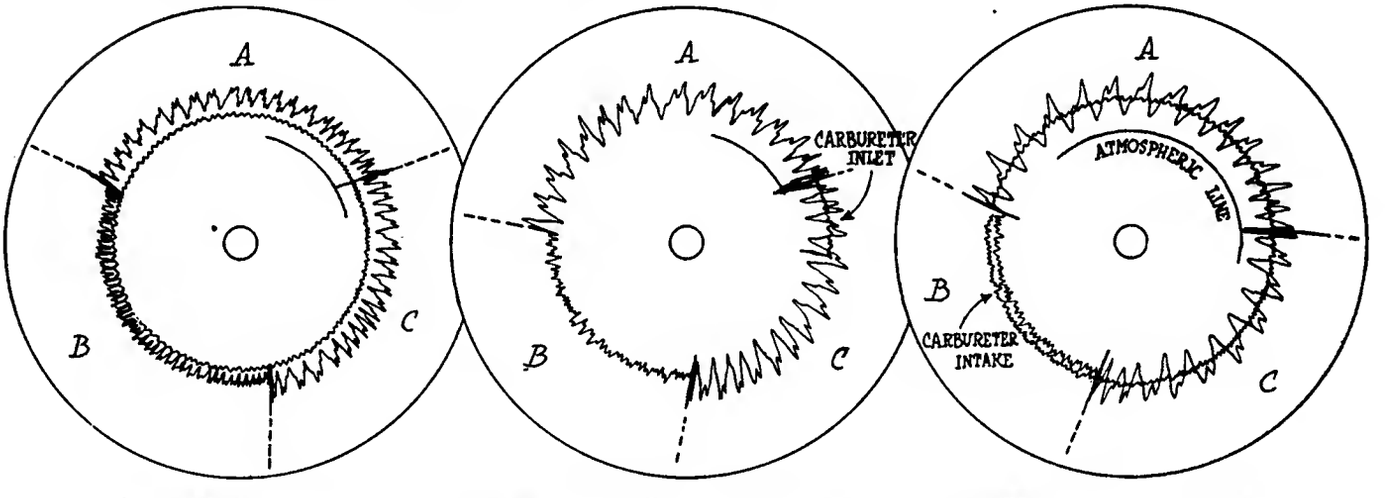

Fig. 13—Same as Fig. 11 but with reversed firing order. Figs. 14 and 15—Similar observations on more open scale

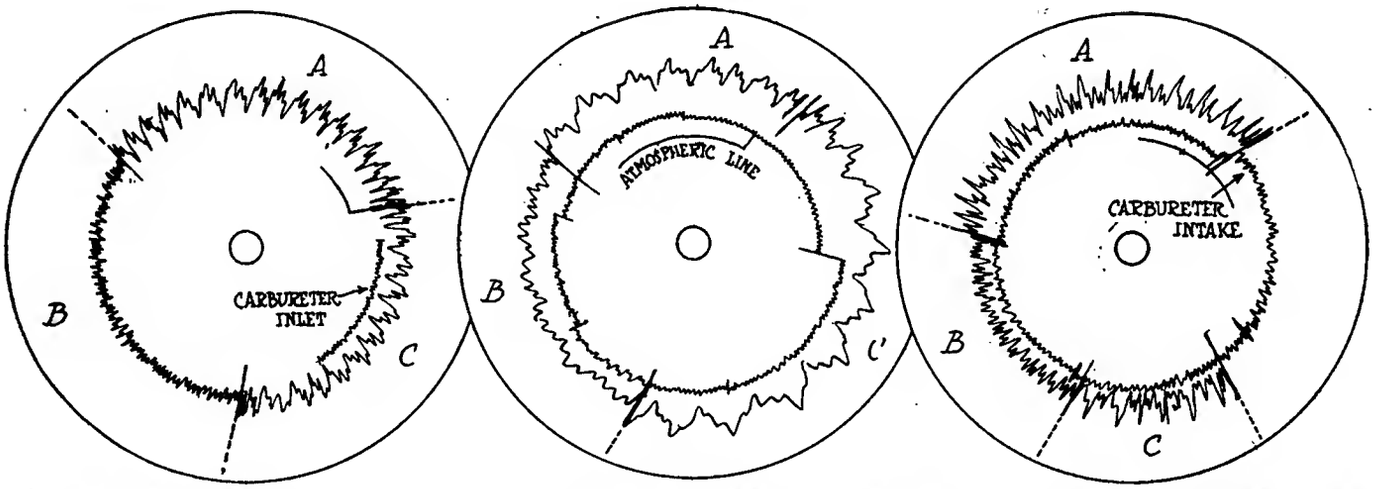

Fig. 16—Effect of returning to original firing order on second engine. Figs. 17 and 18—Showing increases of negative pressure

the camshaft with one similar to that used in engine No. 1, and we here find segment *C* reverting to a similar form to that obtained with Engine No. 1 in operation. This clearly shows the interference which takes place in the air stream by arranging valve closing points in a different manner, and it is very obvious that such arrangements must have a direct bearing upon the volumetric efficiency of any engine, irrespective of the number of cylinders operating. Further, the magnitude of the oscillations of pressure, which show up in the diagram differences of more than one inch of mercury in valve pockets of neighboring cylinders, must have a marked effect upon the uniformity of power production in those cylinders.

Uniform Air Acceleration

Let us finally study the air pressure throughout the system so far as possible in the apparatus. Theoretically, one of two things should occur: In a system relying upon mechanical action, the air should be uniformly accelerated through the carbureter and its velocity maintained at least constant up to its time of entering the engine. If heating is provided and a fuel of low volatility used, such an argument does not entirely hold good, as it may be advisable to provide some form of expansion chamber between the carbureter outlet and the valves.

We will take the former case, and Figs. 17 and 18 show how the negative pressure increases throughout such a system. The observation starts at the center of the diagram. The searching tube is moved from the carbureter inlet gradually toward its narrowest opening, and this observation completes one circuit. The outer circuit then makes observations along the induction pipe as before, segment *B* being the record at point *C*.

Conclusions From Tests

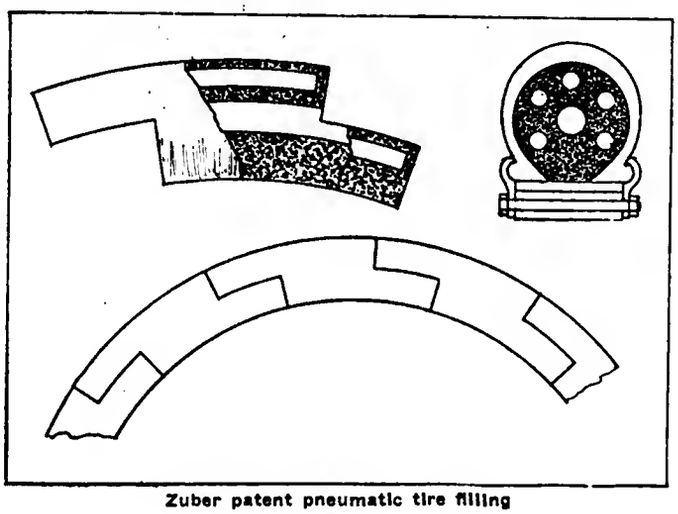
The conclusions to be drawn from the tests and diagrams which form the basis of this article may be summarized as follows:

The variations in absolute pressure during the time of opening of the various valves in any one power unit ordinarily are insufficiently comprehended. These variations are due to the arrangement of branch pipes leading to the valve pockets and also to the valve timing. The closure of any one inlet valve sets up a pressure wave in the induction pipe in the same way that a water hammer is set up in a water pipe, and the effect of this pressure wave depends upon the wave length and the velocity of the working fluid at the moment when its direction of flow is reversed. The interference thus set up in the induction system will be good or bad according to the ingenuity of the designer. In high speed engine work particularly, advantage can be taken of the inertia of the working fluid as it surges backward and forward in an induction pipe, and in an engine of advanced design it is quite possible; in fact the present writer has produced engines having a higher mean effective pressure at maximum engine speeds than at the lower and intermediate speeds. This is obviously an advantage, as it tends to minimize pre-ignition with a high compression motor, and gives the maximum of volumetric efficiency at such times as this is required. Incidentally, the act of charging each cylinder with a uniform weight of mixture at each charge is as important as the mechanical balancing of the engine, but this fact is too often overlooked. It is hoped that the graphical representations accompanying this article will serve to bring home the importance of induction passage design.

Overlapping Tire Filler Sections

MANY attempts have been made to devise a practical tire filler or cushioning body for casings and a number of patents have been issued covering various types. One of the most recent of these is the construction defined in patent No. 1,176,511 issued to Francis Zuber, Brooklyn, N. Y., March 21, 1916. Mr. Zuber's invention is clearly shown in detail by the accompanying illustration.

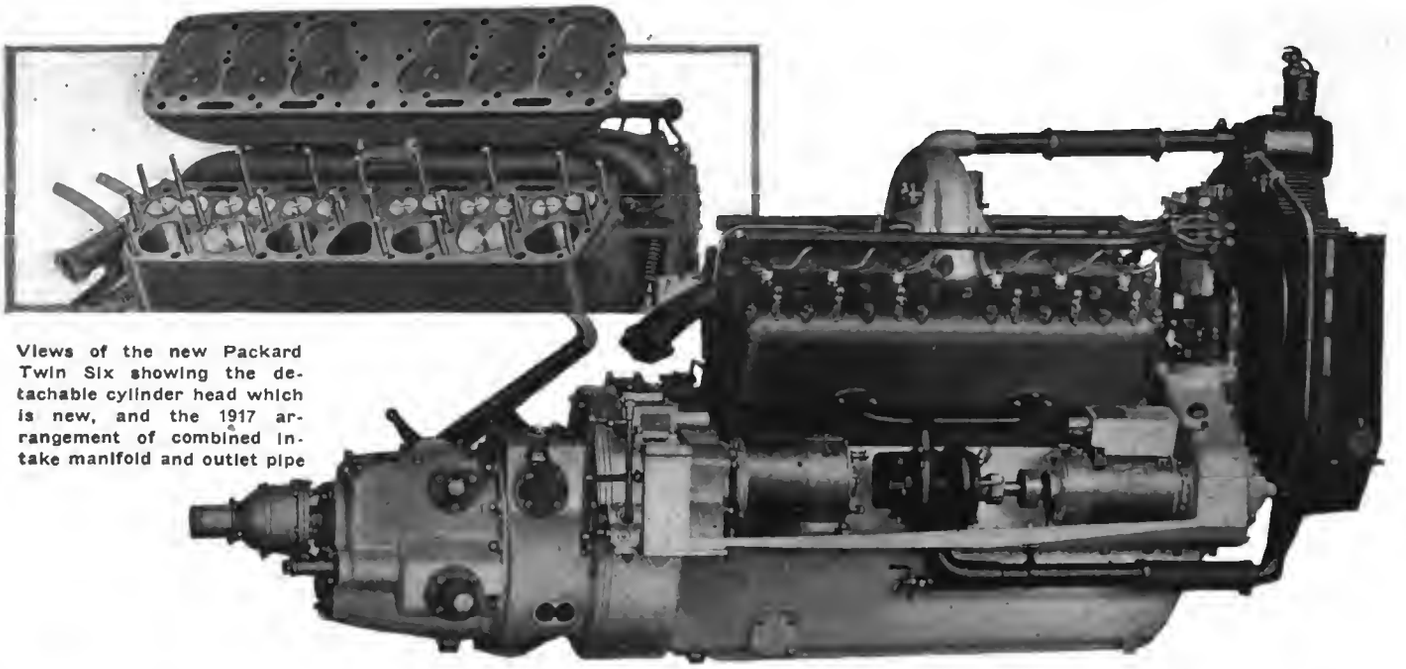
The lower diagram shows the shape and the method of joining the filler blocks, which are of soft, spongy, resilient rubber, the ends overlapping by an ample margin. The filler material is given additional resiliency by the use of air channels in each block, the number and arrangement of these being shown in the two upper diagrams. The air channels of each block have closed ends so that each one forms an air cushion. In practical use in the tire any individual blocks may be removed for repair or replacement.



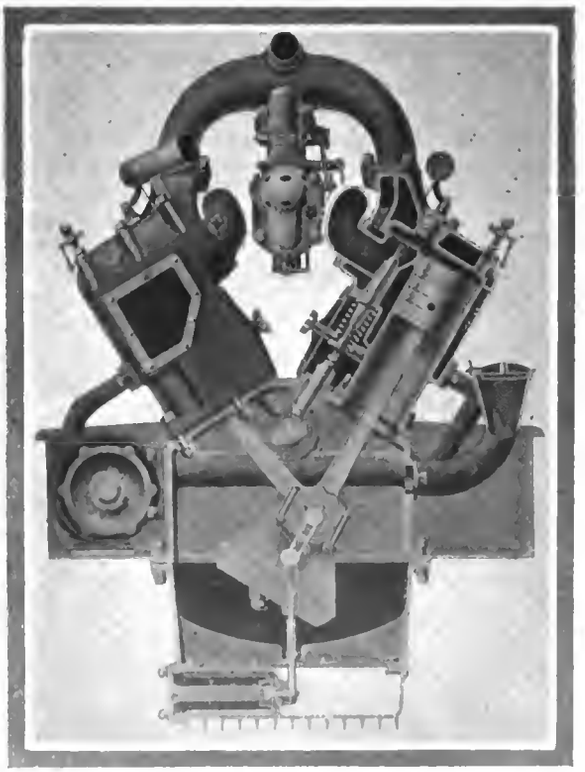
Zuber patent pneumatic tire filling

New Packard Is 2-In. Lower in Build

Detachable Cylinder Head is Only Change on Engine—New Water System Eliminates Pipes—Deeper Frame to Give Body Rigidity—Several Detail Refinements—Prices Raised Slightly



Views of the new Packard Twin Six showing the detachable cylinder head which is new, and the 1917 arrangement of combined intake manifold and outlet pipe



Apart from the detachable cylinder head the only new point in design shown in this view is the crankshaft, of which the webs are now triangular, the same as those used on the crank of the 300 cu. in. aviation engine

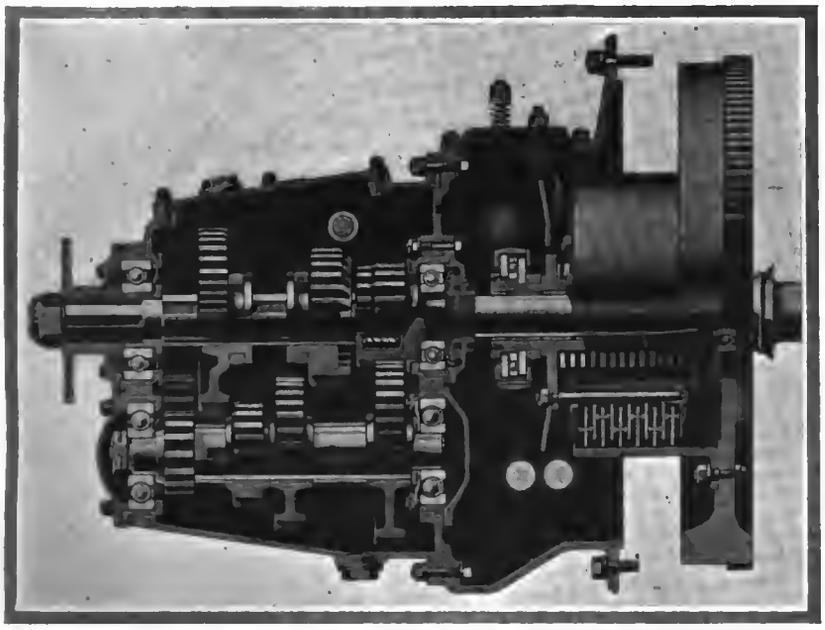
HAVING built close upon 8000 twin sixes the Packard Motor Car Co., Detroit, Mich., are making no changes of real importance for the 1917 series. In matters of detail there are improvements, but the twelve-cylinder engine, the transmission system and the chassis, generally speaking, are the same as before. The twin six Packard was entirely new a year ago, and a year's use has shown no weak spots, no detail that had to be changed.

Equal Size Combustion Spaces

As an example of the sort of changes that have been made, the alteration in the cylinder castings is the most striking. Formerly the Packard has had one piece L-head cylinders, and with these it is not commercially possible to machine every portion of the inside of the cylinder. There is advantage in having the compression exactly the same in all the cylinders, and to do this it is essential to machine everywhere, so the new car has detachable cylinder heads which do not alter the relative positions of any parts of the engine, merely permitting the full machining and, incidentally, making it easier to remove carbon deposit, as the cylinder heads are held on by twenty-five studs and nuts and can be taken off far more easily than could the cylinder blocks.

In conjunction with the detachable cylinder heads there has been a change in the water outlet system. There are now no separate water pipes running from the cylinder heads to the radiator; instead of these the intake manifold is surrounded by a larger pipe, which acts as the water outlet from the cylinders, and a single separate pipe then connects the top center of the manifold to the radiator. The layout makes greatly for accessibility and is excellent for carburetion. The proximity of the exhaust manifolds to the carbureter keep the latter well warmed, and the water surrounding the intake manifold maintains the temperature of the gas.

The position of the thermostat has been altered, instead of being beside the pump it is now mounted in the radiator inlet, that is at the top of the radiator where the outlet pipe from the cylinders attaches.



Gearset and clutch used on the 1917 Packard, which are precisely similar to those employed last year

Here it admits water to the radiator when warm and when cold, by-passes the water down a branch pipe to the inlet side of the pump. This change of position means that the thermostat now occupies the point in the cooling system which normally is at the highest temperature instead of being at the coolest point.

In other respects the engine is the same as before. The dimensions are 3 in. by 5 in., the power output about the same and the details of lubrication, etc., are precisely as on the 1916 car. The aluminum pistons have been changed to the extent that they now have the three rings located two at the top and one at the bottom, the latter acting as an oil scraper. There is also a small detail alteration to the Delco ignition distributer which causes a reduction in the current consumption, while the Bijur generator has been speeded up a little and has an increased output. As formerly, the distributer is situated at the extreme front end of the engine, just behind the fan, but the coils are now located upon the left front crankcase arm instead of being on the cylinders.

New Body Lines

The next change which is noticeable is that the frame has been lowered 2 in., this altering the appearance of the car in a remarkable way. Two inches does not sound a large amount, but it makes a very striking difference in looks. Packard has also abandoned the horizontal end piece on the rear mudguards, which has been a feature for very many years. The fenders now follow the curve of the wheel in a more conventional manner, and this has had the effect of smoothing out the rear end lines of the whole car, giving a much smoother general effect. The touring body is still typically Packard, however, having all the characteristics which give this distinctiveness.

There are two lengths of chassis, the larger is 135 in. wheelbase and the shorter 126½ in., this being an increase of 1½ in. over last year. There are nine bodies for the short chassis and twelve for the long, and all the prices are a little higher, the advance on open cars being $115. This increase is due to the rise in the price of materials the quality of which has not been changed. On the short chassis $2,865 is the price for the five-passenger, and seven-passenger touring cars, for the two-passenger runabout and for a new four-passenger runabout, while there is also a five-passenger salon phaeton at the same figure.

For the long chassis no runabouts are listed, but the price of $3,265 will buy a seven-passenger touring car, seven-passenger salon phaeton, five-passenger phaeton or five-passenger salon phaeton, the word "salon" signifying that the front seats are divided.

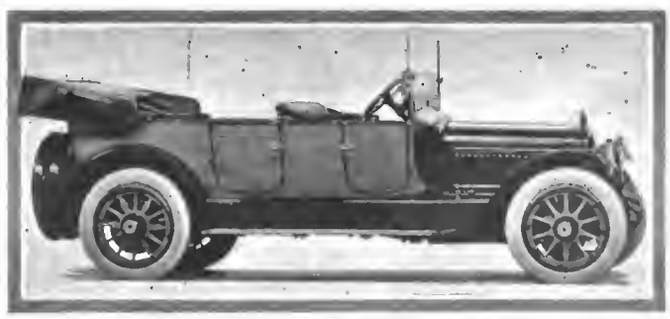
Closed cars on the short chassis are a three-passenger coupé $3,965, six-passenger limousine $4,265, six-passenger landaulet $4,315, and a four-passenger brougham $4,315 also. On the long chassis there are four styles of limousine, one for six passengers at $4,665 and three for seven passengers at $4,715, $4,765 and $4,915. There are also two seven-passenger landaulets at $4,765 and $4,815, a six-passenger landaulet at $4,715 and a four-passenger brougham at $4,715.

Recapitulating some of the details that were new a year ago, and are still retained, mention may be made of the unit power plant which was new to Packard at that time, and is unaltered in any way. The little Hyatt roller bearing in the gearshaft spigot has been entirely satisfactory and, owing to the smooth torque of the twelve cylinders, there has been no difficulty whatever in maintaining the quietness of the constant mesh gears. In describing the 1916 model it was said that the lubrication system, giving pressure-fed oil to every moving part in the motor was probably the most thorough ever used for an automobile. This has proved its worth, and the divided supply inside the crankshaft which gives practically an independent feed to each connecting-rod lower end bearing has worked out entirely in accordance with anticipations. The same is true of the Morse chain front end drive with the eccentric adjustable pinion on the generator shaft, and of the Lanchester vibration damper, which is used as the fan pulley on the crankshaft.

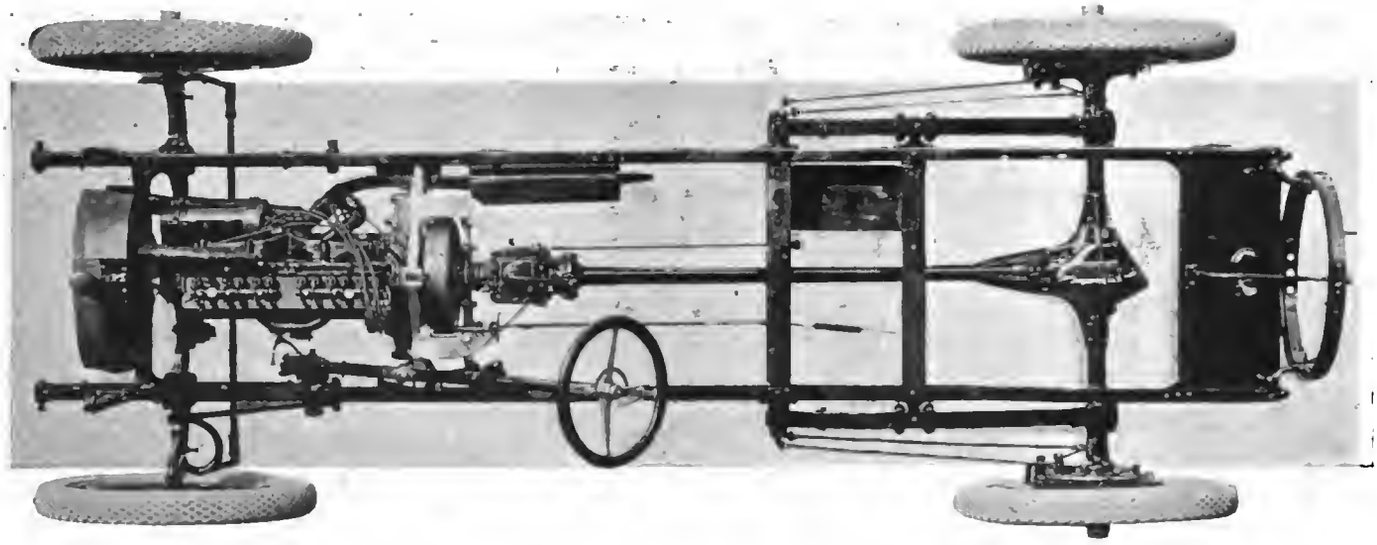
Axles, steering, brakes and springs are unchanged, the platform rear suspension suiting a heavy car particularly well.

Regarding equipment, all Packards will have Goodyear cord tires 35 by 5 in. on all four wheels, the fronts having rib treads and the rears the "all weather" tread; Kelly-Springfield or Goodrich fabric tires can be had instead if the customer so desires. The lamp variations are considerable, as there are side lamps as well as small head lamps combined with the large headlamps. The switch gear is all on the control box on the steering post and gives all the possible combinations of lighting at the touch of a finger.

The accessories include Sparton horn, Waltham speedometer and clock, a complete set of spare lamp bulbs, fuses and a battery syringe. Two extra demountable rims and a tire pump are included. The company wish to draw attention to the fact that they are prepared to vary the specifications of body and equipment when so desired at an extra charge.



1917 Packard touring car which is 2 in. lower than the previous models. Curved rear fenders are used instead of the straight end pattern which Packard has employed for many years



Plan view of chassis showing block six motor on new Hollier car. Detachable head contains valves

Hollier Line Now a Six and an Eight

New Six Sells for $100 Less than the Eight but Has Practically Identical Chassis

A SIX-CYLINDER car as well as the eight is now being manufactured by the Lewis Spring and Axle Co., Chelsea, Mich. It is priced $100 lower than the eight, selling for $1,085 and is a new car throughout. Some of the characteristics of the Hollier eight, however, will be found in the six also, particularly the spring suspension which is the identical 42-in. cantilever and all the chassis frame and structural work.

The six cylinders are cast in a single block with the valves in the detachable cylinder head. With the 3 by 4¼-in. cylinder dimensions a formula rating of 21.60 hp. is given at 1000 ft. per min. piston speed, but the makers claim a much greater output than this due to the high-speed characteristics of the engine and an advantageous shape of combustion chamber due to the use of large overhead valves.

Probably the most noticeable feature of the engine is the accessible arrangement of the valve action. This is entirely contained in the cylinder head, which is detachable, thus allowing the valves to be readily ground besides affording easy access to the pistons and cylinders. All the valves are actuated by a single camshaft by the use of a rocker arm motion. The drive of the camshaft is through helical gears working steel against iron, with the gears inclosed in the usual front case and running in a bath of oil.

Conventional Moving Parts

In the moving parts of the engine conventional practice is used. The pistons are three-ring and the connecting rods alloy steel I-beams. Three bearings support the crankshaft, which is also a special alloy of 1 9/16-in. diameter. The bearings are die-cast white metal, and before the shafts are mounted the running contact parts are ground to a mirror finish.

Oil is supplied by a splash system fed by gravity from a sight feed on the dash. The oil is pumped to the sight feed and at this point has sufficient head to give a positive feed to the splash troughs. The cylinders are oiled from the lubricant thrown off from the connecting rods.

Vacuum feed is used for the gasoline. This is from a 14-gal. tank on the rear of the frame, the tank being connected in the usual manner by a suction pipe which syphons the gasoline to the feed tank on the front of the dash. From here the flow is by gravity to the carbureter.

In the power transmission system there is a leather-faced cone clutch mounted on an aluminum casting. This has a nominal diameter 12 in. and a 2½-in. face. The gearset is in a unit with both the crankcase and clutch forming a unit power plant. It has three speeds forward with the main shaft made from a solid forging of chrome vanadium steel.

Two styles of bodies are furnished as standard. These are a five-passenger touring and four-passenger roadster. On both these bodies, which are designed to be capacious, genuine leather upholstery is used and they are filled with curled hair. The finish is in blue. Full equipment is included at the list price.

New Hollier Six touring car which sells for $1,085

Sawtelle Engine Has Two Fuel Grades

Volatile Fuel for Certain Ignition, Heavy Fuel for Combustion

THE patent rights of a very interesting low-grade-fuel engine invented by Charles A. Sawtelle, have been purchased by Vincent G. Apple of Dayton, Ohio, formerly of the Splitdorf-Apple concern.

Probably the most novel feature of this engine is the fact that it runs on two grades of fuel at the same time. The more volatile fuel is used as an aid to ignition and furnishes very little of the driving power while the heavy fuel is ignited by the explosion of the lighter grade and provides the energy. In working out the details of this design a marked amount of ingenuity has been employed to enable the engine to carry out the somewhat complicated phases of its cycle.

A large part of the mechanism may be comprehended from a study of the vertical section given in Fig. 1. The cylinders are in groups of two, as shown in the section. It will be noted that on each side of the main cylinder *A* there are two smaller cylinders *B* and *C*. These supplementary cylinders are arranged on each side of the main cylinder *A* with cylinder *B* taken care of by the high-grade volatile fuel and cylinder *C* the heavy fuel. It will also be noted that the piston *D* extends across the entire bore at the bottom, carrying two pistons in the cylinders *B* and *C* by means of the rods *E* and also the main driving pistons *F*, which are connected to the connecting-rods *G*.

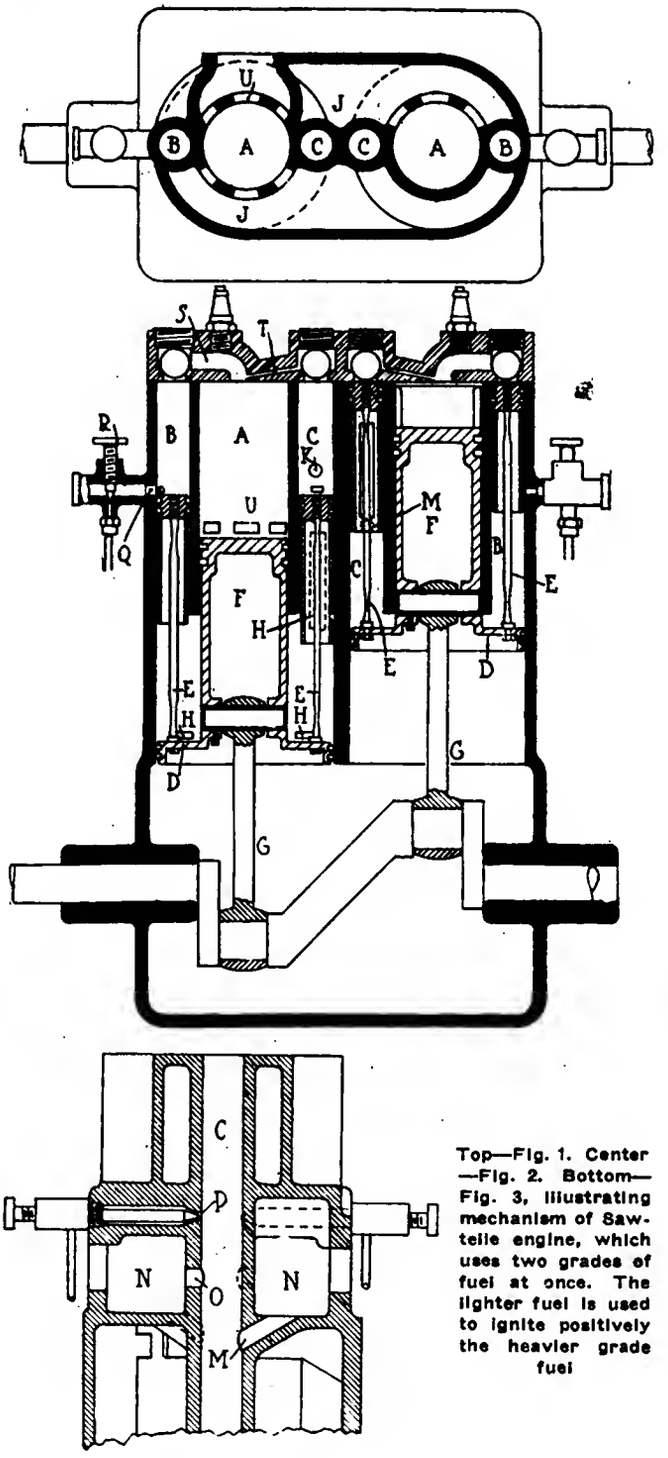
Air ports *H* are formed in the walls of the cylinder and are uncovered when the auxiliary pistons are at the bottoms of their strokes. When the piston *D* moves upward it compresses the air in a passageway *J*, shown in the horizontal section which is so arranged that the compressed air from one cylinder is fed to the adjacent cylinder and acts as a means for scavenging it.

Each of the cylinders *C* carries a piston similar to that in cylinder *B*, but the cylinders *C*, however, have ports *K*, which are uncovered by the pistons and which form admission passages for the heavy fuel. These pistons also differ from the others in that they have slots which are necessary, as will be shown to carry on the operation of admitting the heavy fuel mixed with a proper proportion of air. The mixing means for the heavy fuel and air is shown in Fig. 3. Each of the cylinders *C* has a port *M*, shown in Figs. 1 and 3, which opens into a passage leading to the chamber *N* located in a casting. This chamber extends all around the cylinder *C* and communicates with it again through the port *O*, as shown in Fig. 3, and by means of these ports and passages part of the air compressed by one piston *H* passes over through its slot *O*, the port *M* and the chamber *N* over into the cylinder *C* of the other set.

Piston Uncovers Ports

Studying Fig. 3, it will become apparent that as the piston *H* moves downward it first uncovers the port *P*, drawing in a charge of low grade fuel into the cylinder *C*, then, as it moves down, it uncovers the port *O*, admitting compressed air and thoroughly breaks up the charge of fuel. The cylinder *C* is thus filled with a mixed gas before the piston *H* again starts upward.

Returning to the cylinder *B*, this is in communication by means of port *Q* with the volatile fuel controlled by the needle valve *R*. As it uncovers the port *Q* on the down stroke it admits a charge of high grade fuel and compresses it in the cylinder *B* on the next upward stroke.



Top—Fig. 1. Center—Fig. 2. Bottom—Fig. 3, illustrating mechanism of Sawtelle engine, which uses two grades of fuel at once. The lighter fuel is used to ignite positively the heavier grade fuel

With the cycle thus far explained the main cylinder *A* has on one side the cylinder *B* charged with a supply of high grade fuel and on the other side cylinder *C* filled with low grade fuel under a slight compression due to the admission of compressed air through the port *O*. This gives the low grade fuel cylinder a slight lead on the high grade fuel. The passages *S* for high grade fuel and *T* for the heavy grade are so proportioned that cylinder *A* is filled with the heavy grade fuel, while the volatile product remains in the passage *S*, where the spark plug is located. The effect of a spark is to explode the high grade fuel in the passage *S*, which sends a jet of flame down into the cylinder *A*, thus readily igniting the heavy charge. At the bottom of the stroke the piston *F* uncovers the exhaust ports *U*, allowing the burnt gases to escape by the aid of the compressed-air scavenging arrangement.

Anderson Adds Five-Passenger Roadster

Application of Stewart Vacuum Feed Only Mechanical Change for 1917—Winter Tops for New Models

View of rear deck closed and opened for Anderson five-passenger roadster

ADDING a Stewart vacuum feed system is the only mechanical change that will be made by the Rock Hill Buggy Co., in their Anderson car. In the body line a five-passenger roadster has been added, and this design will be patented. Winter tops can now be furnished on the 1917 cars if desired. A new feature, which is of a merchandising nature, is that all Anderson cars can be painted to suit the purchaser without additional cost.

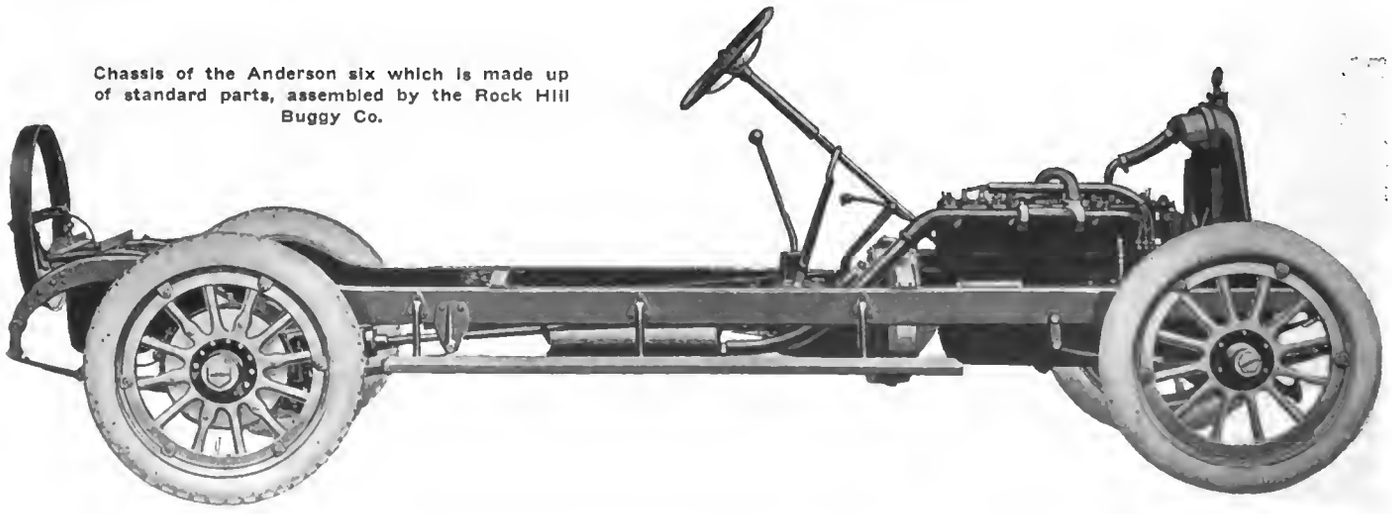
The new body, which is the feature of the announcement of the policy of the company for 1917, was designed to meet the needs of those who prefer the roadster type of body and yet need the passenger-carrying capacity of the touring car. This is different from the general multi-passenger roadster in that the under-deck seat is protected by the top and also has a capacity of three passengers.

When opened to its five-passenger form, the car greatly resembles a five-passenger close-coupled body with divided front seats. The only difference is that there is only one door, but since there is plenty of room between the front seats, it is quite easy to enter and leave the tonneau. When closed, the folding comes down behind the divided seats and makes a body which resembles to a great degree the ordinary two-passenger car with a rear deck.

A full description of the Anderson car was published in THE AUTOMOBILE for April 20, 1916, on page 722.

Standard units are used throughout the mechanical construction of the car. The motor is the Continental six-cylinder 3¼ by 4½-in. L-head type. The S. A. E. horsepower rating is 25.35 and the piston displacement 224 cu. in. The valves are on the right side and are operated through a helical gear drive. Cooling is by pump and oiling by splash pressure with the oil carried in the usual way in the lower part of the crankcase with pressure feed to the main bearings. The cylinders are taken care of by splash. The oil is circulated by a piston type pump.

For carburetion and ignition standard units are used, the Zenith instrument being used on both touring and roadster for carburetion and the entire car being Westinghouse as far as electrical equipment is concerned. The Westinghouse two-unit system is used, operating at 6 volts for starting, lighting and ignition. Ignition advance is automatic, and the system is thoroughly outfitted with ammeter, dimmer switch, etc. The storage battery has a capacity of 80 amp.hr., the electric horn is motor-driven, and armored cable is used in all the wiring. Other electrical instruments used on the car are the cigar lighter, searchlight and trouble light.



Chassis of the Anderson six which is made up of standard parts, assembled by the Rock Hill Buggy Co.

The power tire pump is mounted on the right side of the motor with a sliding gear engagement operated by a hand lever easily accessible on raising the hood. The drive for the tire pump is taken off the water pump shaft which also provides drive for the generator.

The clutch is a Borg & Beck dry disk type, 10 in. in diameter. It transmits the power through a three-speed selective gearbox to an Anderson-Mott floating axle. The front axle is also an Anderson-Mott of reversed Elliott type. The springs are semi-elliptic designed to be flat under normal load. They have phosphor bronze bushings for ⅝ in. bolts in the spring eyes. The front spring has 5-in. play, being 36 in. in length and 2 in. in width. The underslung rear spring has a maximum play of 8 in. and is 56 in. long and 2 in. wide.

The frame construction is simple, being composed of two main members which taper in straight lines from the rear of the car forward. There is a cross member just behind the radiator and another at the rear. Both of these are rigidly connected to the side members by gusset plates. The rear support of the unit power plant and the radiator supporting members also act as virtual cross members, giving the frame construction rigidity although having but few actual parts and consequently being clean and light. The front support of the motor is hung in the front cross member of the frame, giving a three-point suspension of the unit power plant.

Wheels are twelve-spoke types of selected hickory. Spokes are 1⅝ in. wide, and on the rear wheels are 14-in. brake drums. The brakes themselves are completely inclosed within the drums, being of the internal expanding type. The brake linkage is equalized through an equalizing bar which is placed some distance forward of the rear axle.

Hotchkiss Drive

Hotchkiss drive, in which both drive and torque are taken through the rear springs, is employed. This simple type of drive taken in connection with the chassis layout, gives a clean design which should tend to keep the car free of rattle. The speedometer drive is also rattle-proof, being strongly mounted just behind the gearset.

Besides the special equipment mentioned, the car has quick-demountable rims, one-man top, crowned fenders with complete splash guards, ventilating windshield, speedometer, hand pump, repair kit and a complete set of the usual tools.

Inaccessible Nuts

THE detachable cylinder heads now the conventional design in America have been causing a great deal of correspondence in the British automobile magazines this year. The advantages and disadvantages have been reviewed, and many owners of American cars have related their experiences. On the whole there is no question but that the verdict is distinctly in favor of the detachable head, because it makes the cleaning out of carbon so much easier, but there are a few criticisms which are worth noting.

One, perhaps the most common, is that when the cylinder head is detachable the cylinder block should also detach from the crankcase. This is because it is an advantage to clean out the carbon, which deposits behind the piston rings, now and then, while it also permits the condition of the bearings to be judged by feel without the more difficult job of dropping the bottom of the crankcase.

Another is that on some detachable cylinder heads the nuts are so placed that they can only be tightened with a special spanner, and if they are left a trifle loose water leaks into the cylinders. There is nothing but praise for the American gaskets, great surprise sometimes being expressed that these can be used so many times without renewal. Rather curiously, the engine most criticised on account of inaccessible holding down nuts was of British manufacture.

Another point which designers might more often bear in mind is the advantage of using as few sizes of nuts as possible. Really there is no need for more than four sizes on an engine and very little throughout the chassis except for just a few special places which seldom require touching.

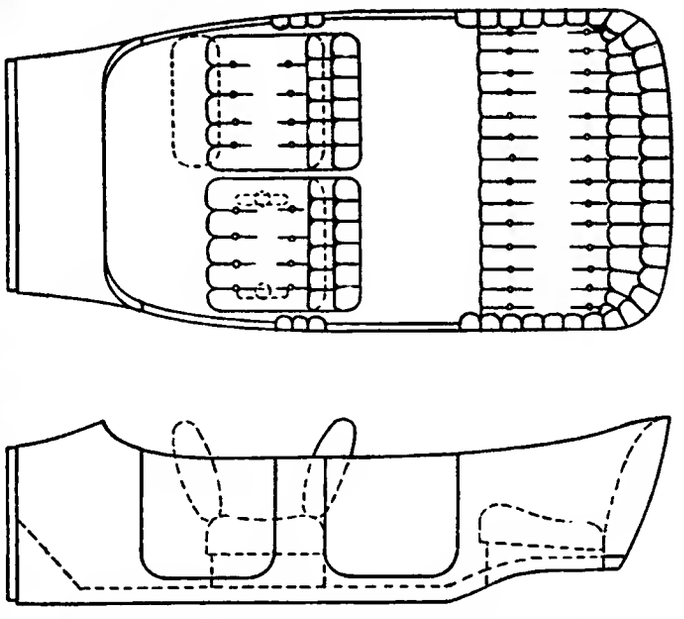
Body Design Permits Swinging Front Seat

Adjustable to Suit the Height of Any Driver—Right Front Seat Can Be Turned Entirely Around

THE accompanying illustration shows a body upon which the designer is applying for a patent. The feature of the body is the front seat which is divided and which is so arranged that the left seat can be adjusted for a driver of any height and can be moved backward and forward so that it will give the necessary leg room to reach the pedals.

The right seat can also be moved and if desired can be turned around so that its occupant can converse with comfort with the occupants of the rear seat. The idea of the body is two-fold. In the first place it is realized that the car cannot be designed to fit other than the average driver and since there are so many people in the world who are not average in stature it is necessary to provide some means for accommodating those who are exceptionally tall or short as the case may be. Thus any driver can take care of the car and operate it in greater comfort and efficiency.

The right front seat on the other hand is often a very bad place to sit because the driver is generally too absorbed to give much of his time to conversation and it is very difficult to talk over the shoulder to the occupants of the rear seat. If a chauffeur is employed the difficulties are greater as the owner of the car, as a matter of form, is compelled to sit in the front seat with the chauffeur while his three guests are back in the tonneau. The movable right seat overcomes this objection. The designer is W. N. Nakamura of Flint, Mich.



Body with adjustable driver's seat and swinging seat for front passenger

The Rostrum

Why Sixteen-Valve Fours Are Made

EDITOR THE AUTOMOBILE:—Regarding the sixteen-valve four, take a four-cylinder engine from 250 to 300 cu. in. displacement and designed to peak at say, 2400 r.p.m., at least not over 2500 r.p.m., would an eight-valve design like the new Wisconsin six-cylinder aluminum motor aviation engine be preferable to a sixteen-valve design?

2—Will an eight-valve motor up to 2500 r.p.m. give as good results as the sixteen-valve, provided one of the eight valves gives the same area of opening as two on the sixteen-valve design? Will not a sixteen-valve four work equally as well as an eight-valve motor at from 500 to 1500 r.p.m., provided the valve timing is proper for the lower speeds?

3—While I realize that the four-valve per cylinder is most appreciated in the higher speeds, the point I wish to determine is: if we have an engine to peak at 2400 to 2500 r.p.m. and still have it work well at from 400 to 1200 r.p.m., is it best to have four valves per cylinder or two valves of an area to give maximum results and equal to the four-valve design?

4—Is it possible to get a satisfactory running motor for a touring car and have it peak at a piston speed of 2500 ft. per minute?

Beemer, Neb. G. S.

—In considering the point that you bring up the actual number of valves should be forgotten. It is simply a question of area and volumetric efficiency. It is comparatively easy to secure quite good volumetric efficiency at low engine speed, but, when the motor reaches speeds of 2500 or more feet per minute piston speed, it is difficult to get the gases into and out of the cylinder in quick enough time and in sufficient quantity to give high engine efficiency. Naturally, the larger the area through which the gases are allowed to flow, the lower the required velocity of the gas and hence the greater volumetric efficiency.

It is impossible to secure what would be the most efficient area with one set of valves for the simple reason that such a large valve as would be required at the highest piston speeds would mean a large exposed disk of thin metal composing the valve head. This disk would soon warp and lose its perfect seat. To overcome this objection makers of high speed engines have been compelled to break the valve opening up into several openings and thus the required area is secured at the expense of extra parts necessary to operate the increased number of valves. This is the sole standpoint which should be borne in mind in questions of comparative merit between engines of different numbers of valves.

2—This is answered under question 1. For a large cylinder it may be necessary to have more valves at lower speeds than it would be for a small cylinder. It is simply a matter of cubic inches piston displacement per minute. If the cubic inches of gas passing through the valves is divided by the area of the valve openings the speed of the gases is given. Hence, the larger the valves, the lower the speed and the lower the speed the nearer the approach to 100 per cent volumetric efficiency.

3—If you could have two valves that would be ample to take care of the needs of the motor up to the speeds that you would require it to run, it would be unwise to use a greater number of valves on account of complicating the valve mechanism.

4—Yes.

Clutch Probably Out of Alignment Causes Plates To Wear Rapidly

Editor THE AUTOMOBILE:—I have a Crow-Elkhart car with a multiple disk clutch, steel against steel. There are twenty-three disks about ⅛ in. thick. I have had several sets of new disks, etc., and had the best garagemen in Burlington at work on it, but they cannot fix it so but that it will leak oil and the disks wear out in a very short time. Could a cone clutch be put in the car without too great an expense and, if so, could I get some clutch used by other cars that would fix it?

If you could advise me any way to get around the trouble it will help me greatly.

Burlington, Vt. J. M. R.

—Evidently the trouble is not so much with the clutch itself as that the alignment is incorrect. What causes this misalignment it is impossible to state without going over the car but it is very possible that it has been given some serious strain which has thrown the drive out of true. Before any clutch can work satisfactorily the parts have to be lined up correctly and therefore the garagemen should be instructed before repairing the worn parts in the clutch to line up the parts so that the shaft from the gearbox is perpendicular to the face of the flywheel and, furthermore, that the center of the shaft is in line with the center of the crankshaft.

Aluminum Pistons for 1912 Chalmers Would Not Give Material Gain

Editor THE AUTOMOBILE:—Desiring to have aluminum pistons fitted to my engine in a 1912 Chalmers 30 car, I would like to have some information before proceeding.

1—Is there any reason why this form of piston would not give satisfaction in an engine of this design? The car is to be used for general purposes.

2—What would be the increase in power? Should the connecting-rods be lightened? If so, in what manner and to what extent?

3—What should the clearance be? Would it be better to have semi-cast-iron pistons fitted to this type of motor? Are aluminum pistons giving entire satisfaction? I have been told that they were unsatisfactory; that they expanded so much under heat that they slapped when cold and were likely to seize when hot. Also that the constant hammering would ovalize the piston pin hole. Who makes Magnalium and is prepared to fit pistons of this metal to this engine?

4—In fitting pistons of this kind, would it be a proper and satisfactory combination to fit one patent ring on the top end of each piston and the remainder of rings to be standard form?

5—In case you do not advise the use of aluminum alloy pistons in this engine, what metal should be used which will

be lighter and give less vibration and more pick-up than regular cast iron?

6—As you know, the upper connecting-rod bearing in this model is a plain ground bearing, the piston pin being secured to the piston and free in the end of connecting-rod. Would it be better to have the pin stationary in the connecting-rod and have bushings in the pistons? If so, would it be satisfactory to alter the construction, by simply drilling a hole through the upper end of connecting-rod and putting a set-screw with extension for cotter pin, inside of the hollow piston pin?

Austin, Tex. H.

—It is greatly to be doubted if there would be any gain from aluminum pistons in this engine. In the first place it is not designed to be run at high enough speeds so that the effect of the aluminum would make any material difference. Secondly, all the other parts are designed for cast iron and hence any benefit in this direction would also be very small.

2—There will probably be a small percentage of power increase, that is, the maximum horsepower or the peak of the horsepower curve would be higher. If you lightened the rods it would probably be still higher. The rods should not be lightened to such an extent that there is too small a factor of safety, but if you lighten the piston naturally the inertia stresses are less and hence the rods can also be lighter.

3—The clearance used with aluminum alloys varies with the alloy employed. In general, the clearances are just about double those of cast iron. Regarding semi-cast-iron pistons you probably refer to semi-steel, so-called, and you would get just as much satisfaction from the regular cast iron. Aluminum is giving entire satisfaction in some cars but in other cars it has not worked out to the satisfaction of the engineering department. It seems to be a fact that a light slap must be put up with before the motor has become warm, but this disappears in a short time and cannot even be detected except by a highly practiced ear. Magnalium, the alloy to which you refer, is an imported alloy and probably cannot be secured in this country at the present time as it is a German metal.

4—This would have to be determined experimentally and would depend greatly on the precise shape of the piston.

5—If any metal will do the work it would be an aluminum alloy.

6—There does not seem to be any great difference between a bearing in which the pin is free in the rod or free in the piston boss.

Installing Ammeter on 1913 Cole

Editor THE AUTOMOBILE:—I have a 1913 model Cole 4-40 touring car that is equipped with a Delco lighting and starting and ignition system and desire to install an ammeter on same. Please give instructions for installing it and what should be the graduations of the ammeter.

2—I use a twelve-cell type SD-3 Exide battery and desire to charge the batteries without taking them off the car. Using a 6-volt direct-current circuit, could I not disconnect the wires from the generator and connect source to them and charge them that way?

3—Which are the generator terminals and at what amperage should the battery be charged? Please give diagrams of the above.

Senath, Mo. L. A. C.

—It is not practical to install an ammeter on this system, as it necessitates running two wires from the ammeter to the cutout relay. This distance being so great, too much resistance is interposed in the charging circuit.

2—The method recommended for charging the twelve-cell SD-3 exide battery is to connect the different groups of cells in series and then charge at a 3-amp. rate. The battery, however, could be charged in another way by disconnecting the wires from the generator terminals and connecting to the wires which were connected to terminals Nos. 3 and 4. With this method, however, 7 volts would be required and the charging rate should be approximately 12 amp. The former method is preferable and is more economical if the battery is charged from a 110-volt lighting circuit. The method is illustrated in the diagram herewith, Fig. 1.

3—This is answered under question 2. The wiring diagram is given in Fig. 2.

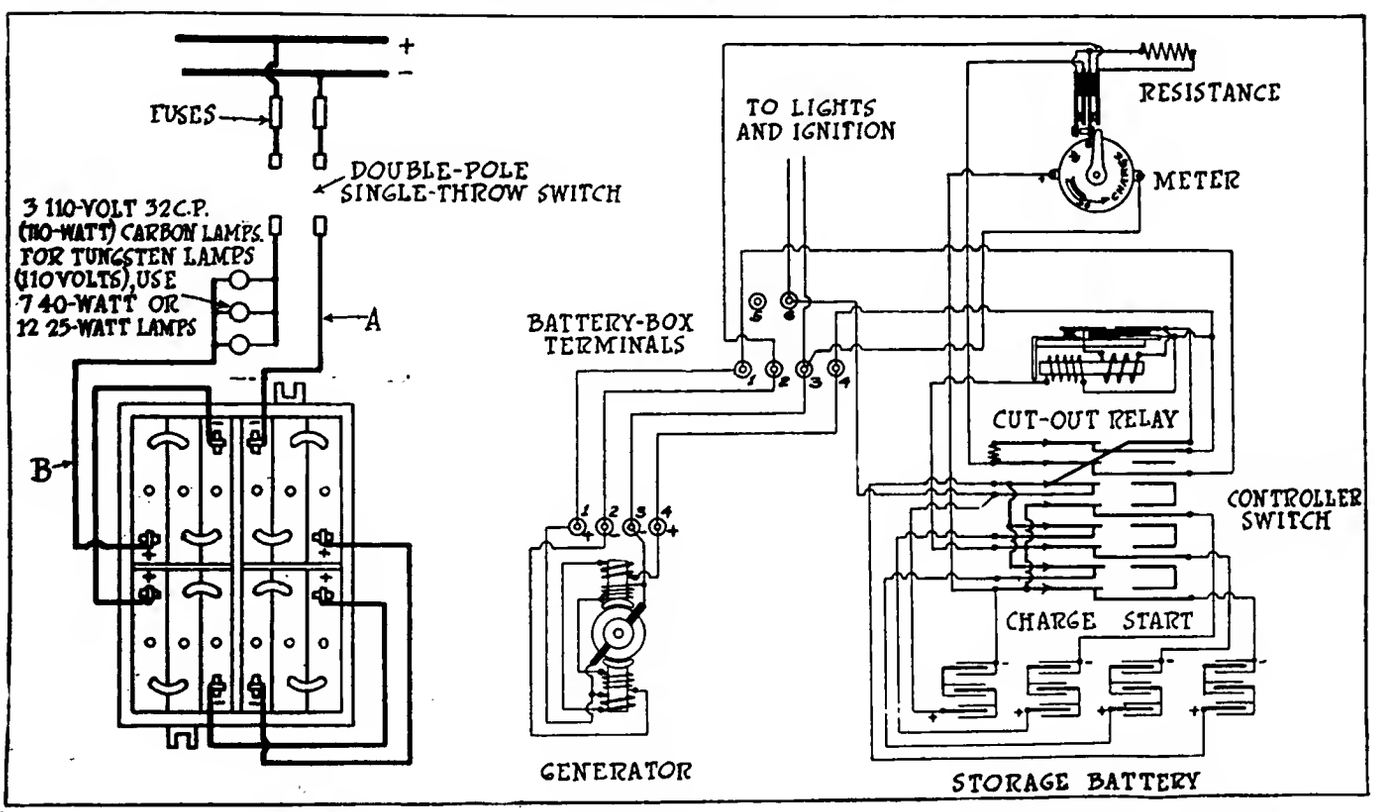


Fig. 1—Charging twelve-cell battery from 110 volt lighting circuit. Fig 2—Diagram of connections with cells in series

The History of the Pneumatic Tire—15

Operation of Device for Registering Tire Rebound—Fabrics Neglected for Years—Skidding Becomes a Factor—Various Corrugated and Other Treads To Prevent Side-Slip

The History of the American Automobile Industry—42

By David Beecroft

LAST week the Duryea machine for recording the number of bounces a tire would make when its wheel was dropped from a given height was mentioned very briefly. This device was simple in construction and was operated as follows: The wheel was placed on one end of a long axle, the other end of which was hinged to the wall so that the wheel could be lifted freely, the hinge simply guiding its fall. A prop supported the axle at the desired height, and pulling out the prop also moved a card across the path of a pencil attached to the axle. This arrangement secured a series of nearly vertical lines, separated, more or less, according to the speed with which the card was moved, and representing by their comparative heights the amount of rebound of the tire. By counting the number of rebounds and dividing 100 by this, the percentage of loss at each rebound was found. The height of the fall could be as desired by changing the length of the prop. The load was easily varied by weighting the axle. Cards were made by dropping on the flat surface, and also on obstacles, and differences of as much as 25 per cent were found between tires on the market at that time.

Fabrics a Minor Matter

With the decline of the interest in bicycles and their improvement and the coming of the motor vehicle, tire fabrics ceased to be considered. So long as the tire was thick enough to be reasonably free from puncture, the buyer was satisfied, and a little matter like fuel economy, lessened mileage, or overheated engine did not concern him. Water was plentiful and he did not go joy-riding to save fuel. It s interesting to note that tire makers and users are now beginning to study again this matter of better fabrics and more resiliency with increased mileage.

Side Slip a Factor

With the advent of the pneumatic tire with its broad, flat surface, and light load, as compared with the narrow, solid tire or even with the cushion tires, used shortly before, it was found that the bicycle would skid easily on slippery surfaces. This matter was of decided importance in a one-track machine, where each thrust on a pedal tended to slip the wheels from under, so naturally, protection against side slipping was early called to the attention of makers.

Some Corrugated Treads

This matter had not been wholly neglected by the solid tire makers. The wide, shallow Star tires already mentioned were in reality corrugated, having a high ridge in the center with shallower ridges on each side. Other makers had fitted their solid tires with grooves of V shape adapted to grip the road, but since these were solid tires, which were not largely adopted by automobile makers, we need not consider them further.

The Jeffery Tread

Jeffery seemed to catch the significance of this most early and brought out his corrugated tread advertised in January, 1894. This consisted of several parallel ridges or beads on the tread of the tire and extending lengthwise thereof. The assumption was that these would grip the ground much as the skate runner does and avoid slipping. It was quite common, in the early days, to make up these tire casings, without molds, and, while being vulcanized, to have them wrapped with muslin or even burlap, which wrapping served much as a mold. When removed, a more or less roughened surface remained, according to whether the fabric was coarse or fine. These roughnesses probably were of little value to prevent skidding, but as molds became commonly used these markings somewhat deepened were reproduced in them in various forms.

New Brunswick Braided Surface

The New Brunswick Tire Co., in January, 1897, advertised a braided surface; the Samson milled tread tire was advertised in April, 1897, while the Bailey studded tire, particularly for preventing skidding, is mentioned in September, 1897. In May, 1897, the Lovell-Diamond advertisement showed a cut having letters on the tire of the wheel, but their placing indicates that they were simply using a convenient space on the cut and not that they were actually on the tire.

The FORVM

SUMS UP DISCUSSION ON OTHER CYCLES ARTICLE AND ADVANCES THEORY OF TWO-CYCLE ENGINE — CORRECTION OF ERROR IN WHEEL ANALYSIS

A Two-Cycle Construction with Unusual Features

By James McIntosh

IF my comment on J. Edward Schipper's article in THE AUTOMOBILE for April 20, and my entry into print in THE AUTOMOBILE for May 18 has anything to do with the array of letters in the June 8 issue I do not know, as there is no direct challenge or reference made outside of a few ifs and ands and a few fears that possibly are more imaginary than real. My later letter appearing in The Forum for June 1 may set at rest the possibility that the four-cycle engine has all the virtue as a means of control, using a throttle with a homogeneous mixture to suit the initial compression for a given throttle opening and a carbureter that delivers a larger proportion of fuel for light loads and low speeds, resulting in low efficiency. This wastefulness is the direct result of the system of control used to suit a cycle that has outlived its usefulness for large powers as applied to large units for marine and stationary engines when weight and space in the former means much.

In each instance it does not appear to be due to the desire to get a simple engine nor is it the desire to eliminate valves in the head, although Sulzer, in his six-cylinder, 6000-hp. engine, has not found the defects and weak points due to heat flow or the lack of efficiency Finley Robertson Porter has experienced. Again, German submarines are not fitted with two-cycle engines simply because they are less efficient, for as to that we have reasons to believe they have been altogether too efficient.

A. L. Milbrath also has some beliefs as to future and attendant difficulty due to bearings leaking because of slight wear and resultant weak explosions in the cylinders and connecting a relatively higher compression and more difficulty to prevent leakage than with the lower pressure, as there is no connection with crankcase compression and cylinder compression nor is either a measure of the other.

F. E. Watts fears that the two-cycle is probably complicated; as an offset, Mr. Schipper states that a good four-cycle 20 per cent efficient at full throttle opening drops to 5 per cent with a one-third throttle. Further, Sulzer Brothers do not seem to worry about retained burnt gases and poor fuel economy, flexibility or control in an engine of 6000 hp. operating a lighting plant requiring close regulation directly connected and economy is not a secondary consideration for units of the size cited.

C. W. McKinley may forget about valve complications. Sulzer has overcome this inherent defect by the use of ports and uses a modification of the three-port system. As to the relative results *The Gas Engine* has this to say: "An analysis of a large number of engines using the actual developed horsepower as a basis and at normal speed shows that the piston displacement of the two-stroke engines is almost exactly 7 cu. ft. per minute per horsepower, while 11.6 cu. ft. is the average for the four-cycle engines, which is about 65 per cent larger than the two-stroke, with corresponding dimensions and speed." This analysis also showed that the piston displacement of the port-scavenging type of engine was no greater than that of the valve-scavenging type for the horsepower developed.

E. G. Gunn seems to fear complication more than he values efficiency. Complication, or lack of efficiency are not virtues nor is simplicity, when results may be had due to additions tending toward efficiency that does not in itself necessarily mean lack of virtue. E. Gruenwald considers an air pump necessary; that is not a defect surely. A four-cycle has valves, tappets, cams and gearing in addition to a piston and cylinder. What special objection can there be to eliminating some of these parts and using the piston as a valve and pump does not seem to me much like adding considerable complication and weight for an automobile engine. In my letter of June 1, I refer to a valve that seems to eliminate at least one other according to standard practice and three according to a racing engine, and I further remove the valve I do use to a place where heat will have no effect on it as it is not in the combustion chamber and controls air only. Also I use not only the air admitted but the mixture to internally cool the piston and pump interior, so that to add to the simplification of the proposition and eliminate or tend toward eliminating one inherent defect in all standard automobile engines, the piston is cooled. This feature may be one solution to Mr. Strickland's piston troubles for the lack of facilities to eliminate the limiting factor in all engines due to some highly heated spot.

Compression in any engine is limited by the heat of some surface, usually the piston head, and then it may be only evident at the center of that surface where the conductivity of the metal is not sufficient to eliminate the heat as fast as it is generated, and is usually evident on the inside in the shape of a red or charred spot the size of which is soon aggravated, due to preignition. Again, if an engine must deliver a number of impulses for a certain horsepower a four-cycle must run double the number of revolutions of a two-cycle or have twice the number of cylinders. As to the virtue of a cylinder delivering one impulse every revolution as against another resting every other stroke to cool off it seems like a joke and to add parts to accomplish this condition seems funny.

F. N. Nutt seems to have had a few unpleasant experiences sometime ago and believes that there is no possible chance for any two-cycle now because the gasoline is poor. There is no apparent real reason for such a fear. Mr. Knight did not succeed in the United States because of a fear that his design was too radical. The Chinese dread new things and as a result they stand still.

Summing up the situation, it is not through doubts and fears that progress is made. To get radical results things must be different. I have outlined a new means of control and it will take more than a few fears to refute the logic cited in my last letter appearing in The Forum for June 1.

In closing I might suggest I can handle a poorer grade of

gasoline due to the fact I can add more heat to make a gas and deliver it where it belongs and yet use pure, cool air and it never touches the mixture until it is trapped into the pumping chamber and piston interior where the cool air remains for light loads three-quarters of a revolution while the total mixture must pass the inner end of the piston, thus reducing its heated walls and head to a point where higher compression can be used than with an engine fitted with a piston where the same air may remain indefinitely, as there is no disturbing influence to change it, and the closer to the head the less it is effective as a cooling medium.

In referring to a cooling medium, it is, of course, assumed that I do not mean to force the jacket water fast enough to condense the energy of a power stroke simply to be able to handle high compressions, but I do believe that poor piston-cooling facilities are evident in every standard automobile engine. I not only cool the piston, but can improve the charge by adding heat to it first by precompression and second by added heat after the charge has been trapped. I will even venture to state that I can take in a larger volume, due to only a part of the charge being heated and that only sufficient to make and retain a mixture while the air is as cool as the atmosphere, and if drawn off, a sleeve encircling the intake pipe may be even cooler. In some carbureters the total air used to make a mixture is heated and the more it is heated the less it can be compressed and the less its volume or value in oxygen.

I believe I have stated a few facts sufficient for the present and can be more specific if occasion justifies further discussion. Of course, I am only stating things in a general way and hope critics will be specific as to comment and not treat the subject on past records but future possibilities.

Corrects Error in Analysis of Rolling Wheel Motion

By C. V.

REFERRING to the communication Analysis of the Rolling Motion of a Wheel appearing on page 192 of THE AUTOMOBILE for Aug. 3, the writer, after careful re-examination of said communication, wishes to call attention to some erroneous statements contained therein.

Being totally ignorant of analytic geometry—the realm in which the proposition belongs—I attempted to analyze *experimentally* the cycloidal curve in question. This curve is transcendental (not algebraic), therefore the equation of the ellipse is only roughly approximate.

Some of the conclusions are also erroneous. For instance, at the top of the second column, where the deduction is made that the maximum velocity of the point *A* is attained when approaching or leaving the ground: it is exactly the opposite, because, from a consideration of the composition of the linear, and the rotational velocity vectors it would seem that the maximum velocity is reached when the point is at the opposite end of a diameter leading to the point in contact with the ground.

Error in Wheel Motion Analysis

THE motion analysis of a rolling automobile wheel, by C. V. in THE AUTOMOBILE for Aug. 3 is certainly very interesting, but one conclusion reached seems to jar against the old theory that the top point of a wheel on a vehicle travels twice as fast through space as the axle, while the bottom point stands still at the instant of contact with the road.

The conclusion referred to is "*the point A* [on the circumference of the wheel] *will reach its maximum speed when approaching or leaving the ground.*"

I believe this conclusion to be erroneous, and I repeat the principal lines of C. V.'s diagram, with his lettering and some additional lines and letters of my own.

Now, while the center of the axle *O* is passing through the parallelogram *A E I G*, the point *A* on the wheel does not reach the intersection of the cycloid *A C B* with the perpendicular *G I*, but only reaches the intersection of the cycloid with the horizontal line *OO1* at *A1*. That is, the wheel will have made a quarter turn only and the original point *A* will have reached the point *A1*. In the second quarter turn the point reaches *A2;* in the third *A3*, and in the fourth, *B*. It will be seen that the point travels about two and one-half times as far while in the upper half of the circumference of the wheel as it does in the lower half. The conclusion mentioned, therefore, must be wrong.

J. W. WATSON.

Alcohol-Benzol Fuel

PARIS, July 30—According to reports reaching here via Switzerland, German army automobiles are being run on a mixture of benzol and alcohol. As soon as Germany found herself cut off from outside supplies of gasoline, a technical committee was appointed to find a substitute. Experiments were carried out with a 1914 Mercedes touring car equipped with an ordinary carbureter, when mixtures of alcohol and benzol were found to give satisfactory results. Summarized, the results obtained in these tests were as follows:

Nature of Fuel Employed		Speed Obtained, M.p.h.	Miles on 1 Liter of Fuel
Benzol	Alcohol		
1 part	1 part	42.2	4.66
1 part	2 parts	41	4.4
1 part	3 parts	39.1	4.3
1 part	4 parts	38.5	4.1
1 part	5 parts	36	3.7
Benzol only		41.6	3.79
Gasoline only		43.49	3.6

Calculating on the rates existing before the war, the benzol-alcohol mixture is the cheapest fuel obtainable. One liter of gasoline cost 9 cents, benzol 8.6 cents, and alcohol 8.2 cents. The cost per kilometer works out as follows:

	Cents		Cents
Gasoline	0.0157	Alcohol-benzol, 50%	0.0125
Benzol	0.01362	Pure alcohol	0.0167

This shows that a 50 per cent mixture of alcohol and benzol is the most economical, and it is this fuel which has been used throughout the German motor transport service. The only inconvenience experienced is the necessity of a preliminary heating of the carbureter. Starting the motor is a difficult task, and on several occasions when the army has been retreating automobiles have been abandoned on this account. This difficulty has been overcome by fitting a secondary tank containing a small quantity of gasoline or ether. A three-way cock allows the supplementary tank to be put into connection with the carbureter for starting purposes. As soon as the motor is warm the reserve fuel is shut off and the alcohol-benzol mixture supplied to the motor. In case of a breakdown near the enemy's lines, or the loss of the main fuel through a bullet or piece of shell entering the tank, the reserve supply is used. This is able to take the vehicle 10 or 12 miles, which is generally sufficient to remove it from the danger zone.

Carbonization of Oils Due to Oxidation

Bureau of Standards Paper Points Out That Polarization Consequent Upon Oxidation Is Main Cause—Cracking Gives Rise to Comparatively Little Carbon

AN interesting technologic paper has recently been issued by the Bureau of Standards of Washington, D. C. It was prepared by C. E. Waters, associate chemist of the Bureau, and deals with data on the oxidation of automobile cylinder oils. One of the points featured in the paper is that the so-called carbonization of automobile cylinder oils is due only a very limited extent, if at all, to cracking but is caused by oxidation and subsequent polarization. In order to learn whether there is any close connection between the rate of oxidation of different oils or an exposure to light and air and their carbonization values at elevated temperatures both before and after oxidation in the light, a series of tests has been made on three well-known automobile brands.

Oxidation in Sunlight

When an oil is oxidized in sunlight, water and carbon dioxide are given off, the oil becomes highly acid and an insoluble oxidation product is thrown down, sometimes after only a few hours in solution. The method of making the determinations was to place twenty-one flasks upon a window sill in the sunlight every bright day for a total of 438 hr. At first the flasks were weighed every day, but later on as the rate of oxidation became less rapid this was done only every 3 or 4 days. The average gain in weight for the three oils was in accordance with the accompanying Table I at different time periods. The fluctuations were not regular, at times, one would be ahead then drop behind and possibly again catch up in weight.

From time to time measurements in increase in acidity due to oxidation were made by chemical means. The oils became more and more strongly acid and the measurements were made by ordinates showing the number of milligrams of potassium hydroxide required to neutralize 1 gram of oil. The results of these tests are given in Table II.

Carbonization Values

The carbonization values of the oxidized oils were determined on samples taken at the same time as those used for determination of acidity. The procedure followed was the same as described in other papers published by the Bureau of Standards, but an electrically heated and controlled air bath was used instead of one heated by gas. Ten gram portions of oil were heated to 250 deg. in 150-cc. Erlenmeyer flasks for 3 hr., allowed to cool and diluted with 50 cc. of petroleum ether. The precipitate was filtered off in a Gooch crucible prepared with a disk of filter paper and covered with a thin layer of asbestos. It was washed with petroleum ether, dried at 100 deg. Cent. and weighed. The results are shown in Table III.

A number of other interesting conclusions and experiments were made in this paper and the summary states the object and results of the tests to be as follows:

In order to determine whether there is any close connection between the rate of oxidation of automobile oils when exposed to sunlight and air and their carbonization values when heated to comparatively high temperatures, a study was made of three brands of oil. The gains in weight and in acidity and the increase in the carbonization value were determined at frequent intervals. In the first two of these tests, two of the oils showed nearly identical gains, the third differing quite noticeably. In the carbonization test the values for the three oils were quite far apart.

Other Determinations

Of minor importance were determinations of the demulsibility, the iodine number, and the Maumené number. The effect of oxidation was to increase the tendency to form emulsions with water. The iodine numbers were lower and Maumené numbers higher for oxidized than for the original oils.

The changes in the carbonization values caused by heating the above three oils and eight others to 250 deg. for different lengths of time were then studied, as well as the changes caused by heating to different temperatures for 3 hr. It was found that in both cases the greater the carbonization value at first, the more rapidly did it increase as the temperature was raised or the time of heating extended. In other words, an oil which has a low carbonization value if heated to 250 deg. for 2 or 3 hr. and an oil showing a somewhat higher value under the same conditions will be farther and farther apart as the conditions become more strenuous.

The carbonization value of an oil is coming to be recognized as a valuable criterion in routine testing, and methods for its determination are finding their way into textbooks, as well as into the journals.

Table I—Average Gain in Weight of Oils Exposed to Sunlight and Air

Total Exposure Hr.	Oil No. 1 Mg.	Oil No. 2 Mg.	Oil No. 3 Mg.
9	9.1	19.3	18.2
51.5	62.6	79.7	75.5
90	88.0	107.7	104.0
130	123.5	141.7	139.2
167.5	154.0	170.9	169.6
205	172.6	188.8	188.2
249	180.7	197.4	197.0
289	195.4	212.7	212.6
327	210.5	227.2	227.2
364	220.4	237.8	237.4
402	229.9	247.4	246.7
438	236.2	252.9	252.1

Table II—Gain in Acidity of Oils Exposed to Sunlight and Air

Acidity	Oil No. 1	Oil No. 2	Oil No. 3
Initial acidity (milligrams KOH)	0.06	0.04	0.03
Acidity after 22 hr	.08	.08	.08
Acidity after 40 hr	.09	.10	.09
Acidity after 69 hr	.19	.21	.22
Acidity after 90 hr	.16	.24	.22
Acidity after 101.5 hr	.17	.25	.25
Acidity after 118 hr	.38	.51	.50
Acidity after 149 hr	.50	.71	.67
Acidity after 174 hr	.86	1.03	1.08
Acidity after 208.5 hr	1.22	1.36	1.43
Acidity after 238 hr	1.44	1.65	1.67
Acidity after 289 hr	2.32	2.74	2.68
Acidity after 333 hr	2.40	2.91	2.94
Acidity after 419 hr	3.40	3.70	3.67

Table III—Carbonization Values of Oils Oxidized in Sunlight

Exposure Hr.	Oil No. 1 Per cent	Oil No. 2 Per cent	Oil No. 3 Per cent
None	0.14	0.17	0.30
22	.23	.26	.38
40	.30	.33	.52

289	.52	.74	1.11
333	.66	.92	1.25
419	.90	1.38	1.75

ACCESSORIES

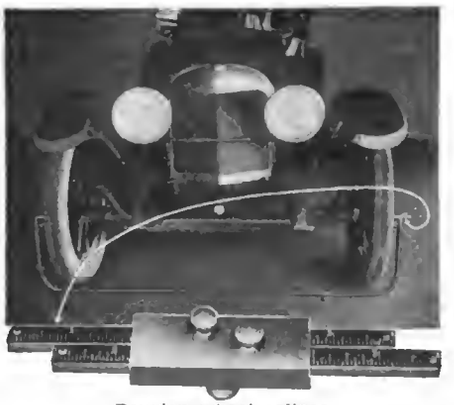
K-W Magneto

THE new Model T is an independent, high-tension magneto for automobile and aeroplane engines. It operates on the well-known inductor principle, having stationary windings and revolving rotor. It will give a spark of great intensity at speeds as low as 60 r.p.m., it is said. This type of construction does away with all moving wires, special contacts, etc. The circuit-breaker is claimed to be unusually fast, and tests have been made up to 18,000 sparks per minute without missing. This is the equivalent of operating a twelve-cylinder engine at 3000 r.p.m. This model conforms to all standard dimensions; it is entirely inclosed and is fully protected against dirt, water and oil. The Model TK is identical, except that it is equipped with an impulse starter. Prices: Model T, four-cylinder, $50; six-cylinder, $52.50; eight-cylinder, $55; twelve-cylinder, $60. Model TK, four-cylinder, $55; six-cylinder, $57.50.—K-W Ignition Co., 2833 Chester Avenue, Cleveland, Ohio.

K-W high-tension magneto

Bowden Wheel Caliper

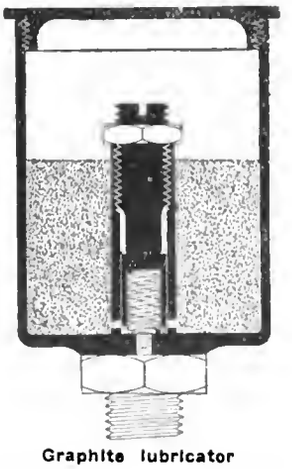
This device consists of a U-shaped member made of tubing which is hinged to the floor by two straps. At one side of the U there is a head which slides vertically, and which contains two members which may be moved horizontally and which are provided with inch scales. Each of these members may be instantly locked in place. First a measurement is taken on the front, using one of the scales, and then a measurement at the back, using the other, and the difference, after allowance is made for toe in, is the amount the wheels are out of line.—Multiform Sales Co., 431 South Dearborn Street, Chicago, Ill.



Bowden wheel caliper

Graphite Lubricator

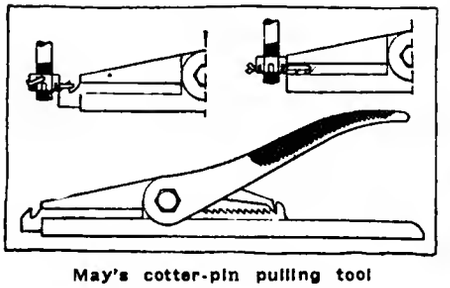
A radical departure in motor lubrication is seen in this device, which supplies dry graphite to the motor. The device is attached to the manifold and delivers the graphite in small quantities. It is a cylindrical shape, resembling an elongated grease cup, which has a valve which is influenced by the slight pulsations of pressure in the manifold, the amount of graphite delivered being in proportion to the pulsations. There is an adjustment to control the rate of feed for various conditions of service. The object of using dry graphite is to keep the cylinders and valve surfaces thoroughly lubricated in spite of the high temperatures to which they are exposed. The graphite does not burn or carbonize, it is said, but fills the irregularities of the metal, giving smoother friction surfaces, preventing leakage and the formation of carbon. The last is obtained due to the fact that the graphite forms a thin coating over the interior of the cylinder and prevents carbon and other foreign matter from accumulating. Price, $6.—Graphite Lubricator Co., 326 Diamond Street, Pittsburgh, Pa.



Graphite lubricator

May's Cotter-Pin Puller

The device pulls cotter pins of any size at any angle, regardless of how inaccessible or badly bent they may be. Pressing the handle operates a ratchet acting on a rack, the front end of which is formed into a hook engaging the eye of the cotter pin. Pressing the handle a few times draws this hook back and carries the cotter pin with it. The device is simple and powerful, and very little effort is required to operate it. Removing the pin in this way straightens it so that it may be used again, and the construction of the tool is such that it is impossible to drop the pin from the tool. Price, $1.25.—Service Shop, 112 Auburn Avenue, Atlanta, Ga.



May's cotter-pin pulling tool

Keystone Wrenches

The large line of Keystone wrenches includes square sleeve and Morse taper ratchet wrenches, reversible ratchet wrenches and adjustable wrenches with straight and S handles. The leader of the line is known as the Westcott adjustable S wrench and has a malleable iron handle with forged steel jaws. It is made in five sizes as follows:

6 in.,	opens to	¾ in.	$0.50
8 in.,	opens to	1 in.	.75
10 in.,	opens to	1⅜ in.	1.00
12 in.,	opens to	1⅝ in.	1.25
14 in.,	opens to	2 in.	1.75

—Made by Keystone Mfg. Co., Buffalo, N. Y. Distributors, Surpless, Dunn & Co., New York City and Chicago.

Nonpareil Trailers

All three models have broad, low express bodies with flareboards, high hickory wheels, Timken bearings and solid tires. The body on the 1000-lb. Model A is 6 ft. long, 46 in. wide, 10 in. deep and has 7-in. flareboards, which are removable. It weighs 360 lb. Model B has a capacity of 1500 lb., a body 8 ft. by 46 in. and weighs 430 lb. The Model C capacity is 1 ton, the body is 8 ft. long, 46 in. wide and 8 in. deep, with sides and ends re-

Keystone adjustable S wrench

Model A Nonpareil trailer

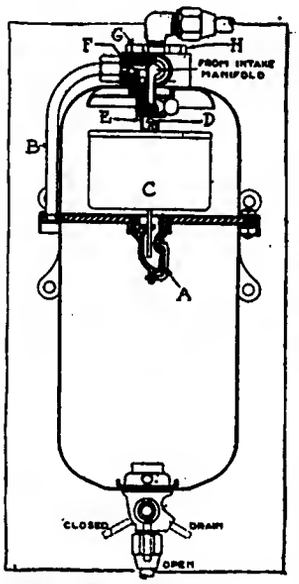
movable; its weight is 465 lb. Prices: Model A, $65; Model B, $80; Model C, $100.—Nonpareil Mfg. Co., Cochranton, Pa.

Tructor for Fords

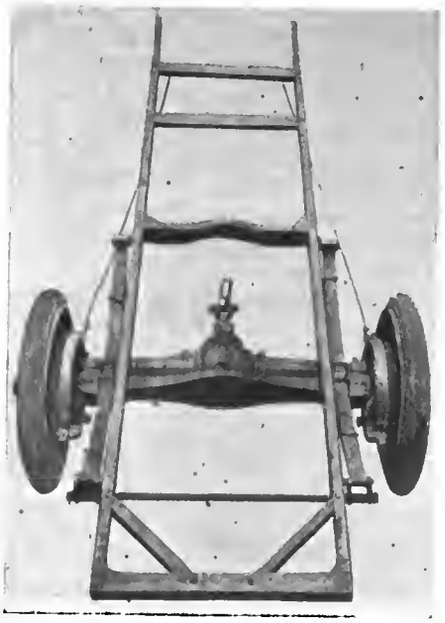
With the addition of a Tructor unit a Ford is readily converted into a 1½-ton truck. The unit consists of a heavy frame, with three cross-members and corner braces, which is slipped over the regular Ford frame, and attached to the rear are heavy springs and an internal gear drive axle. Specifications: Carrying space, 9 ft.; wheelbase, 127 in.; tires, 32 by 3½, solid; speed, 15 to 25 m.p.h.; gear ratio depends on locality; contracting rear wheel brakes, 16 by 1⅞; tread, 56 in. It is said that the change may be made in 1 hr. and it is not necessary to drill any holes. Similar units are built for all other cars. Price. for Fords, $350.—Tructor Mfg. Co., 1502 Michigan Avenue, Chicago, Ill.

Thermo Vacuum Fuel Feed

This is a small fuel tank which is auxiliary to the main tank and feeds directly to the carbureter, eliminating the need for pressure where the main tank is lower than the carbureter. It can be installed on any car, on the engine side of the dashboard. The tank consists of two compartments connected by means of a flat valve *A* and equalizing tube *B*. The upper tank compartment contains the float *C* which operates the suction valve *D* and the valve stem E. When the engine is started a vacuum is formed in the manifold and transferred through the suction pipe to the upper compartment when the valve *A* closes. Atmospheric pressure forces the fuel from the main tank to the upper compartment; the float begins to rise until the valve stem *E* touches the ball valve which is held on its seat by atmospheric pressure. The gasoline continues to enter until the float *C* becomes submerged when it rises and opens the valve and in rising still further closes the suction valve *D*. The pressure in the upper and lower compartments is immediately equalized and the flap valve *A* then opens and permits the gasoline to flow into the lower compartment. The float being held up by the suction valve cannot immediately follow until nearly all the fuel has left the upper compartment. It then drops back, opening the valve *D* and after closes the ball valve. The valve *A* is drawn to its seat and the actions repeated. The valve *F* controls the flow to the carbureter. Loosening the plug *G* permits access to both upper valves and a second plug *H* is provided for priming when necessary. Price, $7.50.—Thermo Vacuum Systems, Detroit, Mich.



Left—Thermo vacuum feed



Tructor attachment for Fords

Polson's leather boot

Polson's Hook-On Boot

This boot may be used as a complete tread, in which case several sections are required for a tire; or it may be employed as a blow-out patch, in which case only one is required. The boot is made of heavy frictioned fabric, vulcanized over a tire form to make a perfect fit. The tread is heavy chrome leather, studded with hardened steel studs. It is attached by a set of adjustable hooks which fit in the rim of the wheel. Prices: 3 in., $1.30; 3½ in., $1.40; 4 in., $1.50; 4½ in., $1.70; 5 in., $1.90.—Polson Rubber Co., Cleveland, Ohio, and Kansas City, Mo.

Duplex Air Valve

A plug, screwed into the intake manifold, to supply additional air. The casting houses the valve opening into the manifold, the valve being operated by a piston working in a cylinder, which is also connected to the manifold. At low speeds the valve is held closed by vacuum, but at higher speeds the reduced vacuum allows the valve to open under the action of a spring and admit additional air. Price, $5.—Duplex Vitalizer Corp., Elmira, N. Y.

S. & H. Top Covering

Complete outfits are made so that anyone may re-cover a top in a very short time. The equipment consists of roof and back curtains and with or without side curtains. Top covers for all the standard cars are carried in stock, and for others measuring blanks and instructions are furnished so that anyone may take the measurements, send them to the factory and receive a cover that will fit. Price, $5.95 to $7.96.—Split Hickory Wheel & Top Co., Hunt and Sycamore Streets, Cincinnati, Ohio.

Broadening the Base of the Sales Field

SELLING Ford cars through a vastly increased number of retailers will be beneficial to the industry.

It will benefit the manufacturer and the consumer.

There is no retail trade in the world that has not gained by the abandonment of restricted selling, and there is every reason why the automobile business should benefit also.

Hitherto, a man wanting a Ford car has had one place only where he could buy it in his locality. Now he will have a dozen or more. Instead of Ford cars for a certain territory all passing through one man's hands, they will be handled by any substantial retail trader who wants to sell them and will undertake to give proper service. They will be easier to buy, and, in a sense, easier to sell. There will be far more men trying to sell them, thousands more people making a living through handling the Ford car.

The step seems revolutionary because it is absolutely new to the automobile business. Actually, however, there is nothing so very remarkable about it, because it represents a stage in the evolution of a business which has been reached and passed by many other industries. Recently we have seen the decline of a territorially restricted form of retailing in the talking-machine business, coupled with an enormous increase in the number sold. To-day the piano trade is well on its way along the same line; and so it is with many other articles both cheap and costly.

That the Ford example will be followed by other manufacturers of inexpensive cars is certain. The change is logical, is in accord with the immense modern development of business which has made our homes so much better equipped, and has provided those innumerable refinements of life which have made it possible to maintain the pace of modern existence.

There is, of course, a limit. Articles which cost so much that they are not in everyday demand cannot be stocked by every trader. Only a few jewelry stores have $10,000 gems in their safes, only a few furriers $5,000 coats. So with automobiles we shall find that there is a stage where specialized selling will still pay all parties concerned better than generalized selling. To state the dividing line would be a dangerous prophecy. It is certainly not less than the price of a piano, not less than $500 to $750; it may very likely prove that $1,000 is not too high, or even a little more than that.

The excellent Ford principle of maintaining a fixed, low price for every spare part, and for upholding the price of the new car at the catalog figure, will not, of course, be affected by the abandonment of territorial restriction. Such schemes are a paramount essential to the automobile user.

Gear Ratios

AFTER a year of experiment with high gear ratios of nearly five to one on both low-priced and high-priced cars, manufacturers appear to be fairly well satisfied with the results. Whether this satisfaction will be maintained, however, is not yet to be decided. Twelve months ago it was pointed out that the average piston speed of the American automobiles of 1916 was far higher than anything ever attempted before, and predictions of rapid wear with excessive fuel consumption were made by all the more conservative among the engineers. The bulk of the past year's output is barely in the hands of the user, most of the deliveries have taken place since April 1, so it is too early yet to say anything about durability. On the subject of fuel consumption though, there has certainly been some complaint. It is possible to argue that the gearing ought not to affect this, but the fact remains that it does do so, probably because the internal friction of the engine increases in some proportion to the piston speed.

There is a feeling in some quarters that next year will see a change back toward the gear ratios common in 1914, an average high gear ratio of between 3.5 and 4 to 1, that is. Observation suggests that the majority of drivers never make use of the full high gear ability now provided, that is to say, they do not in practice try to run at 2 m.p.h. without shifting gears. It is certain that the limit of lowness in gearing has been reached; it will be interesting to see in another year's time whether it has not been exceeded.

V-Ray Plug Now Being Made

Stewart-Warner Corp. Starts Manufacture of Same in Its Speedometer Plant

CHICAGO, ILL., Aug. 15—The Stewart-Warner Speedometer Co., which recently purchased the V-Ray Co., Marshalltown, Iowa, maker of the V-Ray spark plug, has changed the name of this product to the Stewart V-Ray spark plug, and has started manufacture here in the speedometer factory. The plug will be distributed through the regular selling channels of the Stewart-Warner corporation. The Stewart V-Ray plug has a porcelain core made of Petriflint, the process for the manufacture of which is owned and controlled by the Stewart-Warner corporation. There are four sparking points. The plug has a universal cap which, it is said, fits practically every cable terminal in use.

A. O. Smith Insures Every Employe

MILWAUKEE, WIS., Aug. 12—The A. O. Smith Co., Milwaukee, Wis., has taken out a group insurance policy covering every employee in the service more than one year. Each employee received a life insurance policy which is accumulative with each year of service until the amount reaches $1,000. The policy costs the employee nothing, the company bearing all of the expense of premiums and other charges. A recent innovation is the installation of a motion picture outfit in the main bay of the big shop, and every Monday and Friday noon the employees gather for luncheon, during which time popular and educational reels are thrown on the screen.

Rich Tool in M. & A. M.

NEW YORK CITY, Aug. 15—The Rich Tool Co., maker of engine valves and miscellaneous metal specialties, Chicago, Ill., has been elected to membership in the Motor and Accessory Manufacturers, the national accessory organization. This organization now has a total membership of 235 and controls the majority of the accessory show space at the National shows in New York City and Chicago.

Duplex Co. Earned $41,110 in 1916

CHARLOTTE, MICH., Aug. 11—The Duplex Power Car Co., during the fiscal year 1916, earned $41,110.03, which is very much better than the previous season was, and certainly compares favorably with conditions three years ago, when there was an indebtedness of over $30,000. Stockholders present at the meeting subscribed about $20,000 of new stock and probably $30,000 worth will be offered for sale soon. The board of directors and officers which were re-elected are: F. P. Town, president; F. S. King, vice-president; Fred Murray, secretary; H. H. Bryan, treasurer. Allen White, J. H. Brown and William Cooley are the other directors.

Republic Motor Truck Expanding

ALBANY, N. Y., Aug. 15—To take care of a new policy of expansion, the Republic Motor Truck Co., has incorporated in this State with a capital of $1,312,500. There are 72,500 shares of stock, 62,500 of which have no par value, and 10,000 with a par of $100 a share. The directors are C. C. Bellows of Forest Hills, L. I.; E. C. King of Pelham Manor, and H. W. Smith of Larchmont.

Oakland Adding 800 More Men

PONTIAC, MICH., Aug. 11—The Oakland Motor Car Co. factory is to be considerably enlarged, so that 800 more men may be employed within the next few months. New buildings will include a large saw-tooth, one-story machine shop, enlargement of the warehouse and stockroom department. Recently a large basement was added to one of the present manufacturing buildings, making the latter really a two-story building. $50,000 will be spent within the next 12 months for additions.

New Name for American Jack

HICKSVILLE, OHIO, Aug. 14—The American Automatic Automobile Jack Co. has reincorporated as the Maumee Valley Mfg. Co., with capital of $100,000, and will take over the Coller show case factory.

Continental to Build Big Machine Shop

MUSKEGON, MICH., Aug. 11—About 30,000 sq. ft. of floor space will be added to the Continental Motor Co's., factory here through the erection of a large one-story, saw-tooth machine shop building and other minor additions to the plant. Fifteen hundred more men will be employed bringing the total up to 4500. At present 3000 men are employed on the day and night shifts.

Enger Motor Car Co. Incorporated

CINCINNATI, OHIO, Aug. 12—The Enger Motor Car Co. has been incorporated with a capital stock of $4,000,000 to take over the business of manufacturing the Enger car, which has been on the market for some time. The incorporators are F. J. Enger, D. L. Jones, G. W. Platt, E. E. Lincoln and Edward Ritchie.

Hassler Building Absorber Factory

INDIANAPOLIS, IND., Aug. 9—The Robert Hassler Co. is erecting a new No. 3 Austin building 300 ft. long to cost $45,000 for its shock absorber business.

54,700 Chevrolets During Year

Production Plans for Next Year Call for 100,000 to 125,000 Cars

NEW YORK CITY, Aug. 15.—The Chevrolet Motor Co. during the year ended Aug. 1 turned out 54,700 cars, including the output of the Canadian factory, thereby entering the list of the seven largest producers in the country.

The company will turn out about 10,000 cars this month, and plans for next year call for 100,000 to 125,000 cars. The maximum schedule projected for the summer months of this year has not been completely met on account of the delays in obtaining raw materials, particularly brass and copper.

The treasury position has been improving steadily. Current assets are now over $25,000,000 as against $8,000,000 at the time of the organization last fall.

Standardize Truck Controls

(*Continued from page* 257)

gineering, and Auxiliary departments of the army would be truck users with somewhat different requirements and that other users would be the Signal Corps, the Aviation Corps and the Navy. The Truck Standards division is working in conjunction with the S. A. E. Military Transport committee on this matter, and is expecting a request for special work in the near future. At the Buffalo meeting it was suggested that if possible the division should commence discussion of specifications for that size and type of truck likely to be most in demand which would be the one for the Quartermaster's department.

H. D. Church, chairman of the division, presided and there was a good representation of the membership present. General Manager C. F. Clarkson, chairman of the Military Transport committee, was also in attendance.

More Meetings Scheduled

Meetings of most of the divisions are scheduled to be held during the latter part of August and the whole of September. The next general meeting of the whole standards committee will take place on or about October 12. The Research division hopes to be able to make further recommendations for testing performance, while the Electrical Equipment division will have further lamp tests and a number of other matters to report. Important reports from the Engine and Transmission division and the Miscellaneous division are also expected. These divisions have had several matters brewing and a report is expected.

Gasoline Still Dropping in Price

Lower by 1 and 2 Cents in Important Centers—Up Slightly in Portland, Ore.

NEW YORK CITY, Aug. 15—Gasoline continues to drop in price throughout the country. Declines of from 1 to 2 cents occurred last week, and further reductions are predicted. The recent reduction in prices by the leading gasoline companies, it is stated, was caused by a threatened overproduction. It was feared that the output would overreach the demand and well-drilling was discouraged as a result.

Reports from different sections of the country show a steady decline. New York City prices again declined 1 cent, making a reduction of 2 cents a gallon within 3 days. The spot gasoline basis was nominally steady at 23 cents per gallon in steel barrels to garages and 25 cents to consumers.

Portland, Ore., prices have proved an exception to the rule. Instead of a reduction prices have been advanced 1 cent and gasoline is now retailing throughout the city at 20½ cents per gallon.

Gasoline at the present time is selling lower throughout the South and Southwest than in any other section of the country. The Standard Oil Co. is now selling gasoline in New Orleans at filling stations at 19½ cents, as against 21½ cents a month ago. A further cut is expected. Gasoline in Dallas is still selling for 19 cents, with prospects of no decrease. Although reductions of 10 cents per barrel have been made in Oklahoma and Louisiana crude oils, the price of gasoline is not expected to go much lower in this part of the Southwest. One automobile dealer in Dallas will start on Oct. 14 a novel plan for selling his customers gasoline. He will furnish them with gasoline and oil at cost. A service station will be opened at the company's plant.

Louisville, Ky., prices have declined 2 cents during the past 3 days. For several months the fuel has been retailing at 23 cents, but since Thursday it has been selling at 21 cents. The Louisville branch of the Ford company continues to sell gasoline at 20½ cents a gallon to Ford owners only.

Prices throughout the Denver, Col., territory remain unchanged, wholesaling at 23 cents to the garages and filling stations. New Jersey prices were reduced last week 1 cent and customers are now paying from 24 to 26 cents a gallon. The wholesale price is 21 cents to garages. Gasoline declines were reported yesterday by the Atlantic Refining Co. in Philadelphia from 25 cents to 24 cents, tank-wagon basis. Pittsburgh quotations by the principal oil companies have been reduced 1 cent a gallon, to 26 cents. This follows three reductions in the price of crude oil, a total of 25 cents a barrel.

Lower prices are now prevailing throughout the New England section. Last week Boston prices dropped 1 cent, from 25 to 24 cents wholesale. The dealers then announced a 1-cent drop. Some of the dealers are wondering about the retail price, which varies from the wholesale to 2, 3 or more cents above the oil company's price.

The gasoline situation in Milwaukee has caused one independent oil refiner to pit its forces against those of the Standard Oil Co. by the medium of newspaper advertising. Answering the full-page advertisements being published by Standard Oil in all Milwaukee newspapers, the Wadhams Oil Co. is using large newspaper space to explain why it chooses to sell Wadhams gasoline exclusively and why its prices are higher than the 18.6-cent price offered by the Standard Oil Co.

—

Dale Takes Over Jordan and Thianna for New York

NEW YORK CITY, Aug. 15—The Simplex Automobile Co., New Brunswick, N. J., has taken over the Metropolitan distribution of its car. John G. Dale, who has handled the car for several years, will take over the Jordan car and the Thianna, a high-priced town car.

The Simplex company, which takes over all of the unfilled orders and contracts, has rented for a term of 5 years, the store and basement of the new building at the southeast corner of Fifth Avenue and Fifty-eighth Street, and will establish there its local sales and showroom.

The Jordan car will be handled at the old location of the Simplex, 240 West Fifty-ninth Street. According to present plans the territory included under the new arrangement will include the Metropolitan district and the surrounding territory reaching as far as Bridgeport, Poughkeepsie, New Jersey and Long Island.

The first shipment of Jordan cars to be made by the Jordan company reached this city by express to-night and consisted of one carload of three touring models, consigned to Mr. Dale.

—

Ross Prices Raised $200

DETROIT, MICH., Aug. 15—The Ross Automobile Co., this city, has increased the price of its seven-passenger touring car and three-passenger roadster $200 to $1,550. This raise goes into effect Sept. 1 and was caused by the increase in the cost of raw materials and a number of refinements for the new models.

Tractor Men Debate S. A. E. Merger

Opinion Divided but Probably Owing to Misunderstanding —Gov't Favors Plan

FREMONT, NEB., Aug. 10—The Society of Tractor Engineers has decided to take definite action at its next general meeting in Minneapolis as to whether the society will combine with the Society of Automobile Engineers or remain a separate organization. This decision was voted at a meeting held here last night, when representatives of the S. A. E. and the S. T. E. attended for the purpose of considering the advisability of the tractor engineers uniting in the proposed Society of Auto-motive Engineers.

George Strite, president of the Society of Tractor Engineers, expressed a general opinion of the tractor men at present when he said all agreed that on getting results all of the tractor men have realized the work of the S. A. E. He instanced the value of the S. A. E. tread standard, stating that tractor men would find it better than the U. S. tread, and that the S. A. E. has a complete organization for the standardization of parts. He voiced the chief objections of the tractor men when he said that the latter seemed not to understand the reason for the S. A. E. urging the combination, the tractor men asking, "Does the S. A. E. want to steal our stuff?"

S. A. E. Not to Absorb

H. L. Horning of the Waukesha Motor Co. presented the subject to the tractor engineers of being a member of the S. A. E. and the S. T. E. He brought out the point that it was not the idea of the S. A. E. to absorb the other associations, but that the Society of Auto-motive Engineers would be the hand of which the different organizations would be the fingers and thumbs.

The United States Government, Mr. Horning said, had expressed a wish that these organizations be to a certain extent under one head, in order to make its negotiations and recommendations for the standardization of the allied lines more feasible, and the object of the meeting last night was to determine arrangements with the tractor men.

George W. Dunham, president-elect of the S. A. E., spoke on the advantages of the affiliation, and the plan was outlined by Coker F. Clarkson, general manager of the S. A. E. So far as the management of the combined societies is concerned, this would be in the hands of a council constituted similarly to that of the S. A. E., except that there would be an addition of four vice-presidents, one from each of the affiliating bodies. Each

of the societies would retain its identity to a certain extent, having its own meetings and being chiefly in control of the standardization of elements which entered mainly into its own industry. In the general meetings of the proposed Society of Auto-motive Engineers, which would correspond to the semi-annuals of the S. A. E., the individual societies would have as much part in the presentation of papers and in the discussion as they had material to offer.

The movement toward the affiliation of the five engineering bodies identified with the self-propelled vehicle industries which has been proposed by the Society of Automobile Engineers already has resulted in plans for concerted action by the aeronautic engineering society and the motor car engineering society, and there are strong indications that the engineering societies of the tractor, motor boat and stationary internal combustion engineers will co-operate in a general proposed society.

Texas Tractor Demonstration at Fair

DALLAS, TEX., Aug. 12—Texas' second tractor show and demonstration will be held at the Texas State Fair grounds during the 1916 fair, which opens Oct. 14, according to J. C. Duke, superintendent of this division of the state fair. It was decided to hold this demonstration, following the great success of the national demonstration conducted here in July. Indications are, said Mr. Duke, that this demonstration will be nearly as big as the national.

Forbids Use of Trailers

MILWAUKEE, WIS., Aug. 12—The city council of Escanaba, Mich., has passed an ordinance prohibiting the use of trailers on motor trucks. The same law fixes the maximum speed of motor trucks at 8 m.p.h. and the maximum load of any vehicle at 8000 lb.

A. C. A. Seals on Marmon Car

Tags in Dozen Places to Check Authenticity of Transcontinental Record

SAN FRANCISCO, CAL., Aug. 14—Authenticity was the keynote of the system used by the Marmon company in carrying out the checking work on its transcontinental car which established the record last week. The Automobile Club of America was the official medium selected by the Marmon company to do this checking. The car was sealed in a dozen places by a representative of the club in New York City and on its arrival in San Francisco the California representative checked the seals. The run was made in 5 days, 18 hr., 30 min.

Out of twelve seals put on the car at the beginning of its run, eight were intact. Of the remaining four, three were gone and the other broken and hanging on the car. Those seals that were missing were placed on the transmission case to the torque tube; on the bolt through the differential case; and on the left front spring. The seal on the torque tube to the differential housing was broken but hanging to the car.

After thoroughly investigating the original seals on the car, certain identification marks on the car were gone over. It was found that the original six wheels were gone. The rest of the parts were found intact with the exception of the socket on the torque tube end which had been moved or repaired.

Among those who observed and checked the Marmon transcontinental car were Arthur Metzler, Buffalo *Times*, Buffalo, N. Y.; Walter A. Kiedaisch, Erie, Pa.; H. H. Flook, Des Moines *Capitol*, Des Moines, Iowa; Jones H. Clark, Jr., Omaha *World-Record*, Omaha; D. O. Hodges, North Platte, Neb.; Vern Hinkley, Cedar Rapids, Iowa, and Stuart Gayness, care *Examiner*, San Francisco, Cal. Among those who reported the progress of the car were Norman E. Mack and George K. Fraley of Buffalo; Western Auto Transit Co., Rock Springs, Wyo.; A. E. Hubbard, Evanston, Wyo.; W. R. Reynolds, Eureka, Nev., and Western Union operators at Fallan, Nev., and Austin, Nev. In addition the following either acted as pilots or provided pilots: Cahill Brown Co., Syracuse, N. Y.; Flower Webster Cutter Co., Erie, Pa.; C. L. Sturtevant, Toledo, Ohio; Louis Disbrow, Cleveland; Van Riper & Engman, South Bend, Ind.; William Binz, care Marmon Chicago Co., Chicago; Lattner Bros., Cedar Rapids, Iowa; O. W. Garlock, Des Moines, Iowa; Ryan Motor Car Co., Omaha and Lincoln, Neb.; W. S. Rutherford and Carl Frickey, care B. F. Goodrich Co., Omaha, Neb.; Jack Harter, Pine Bluff, Wyo.; D. R. Gainard, Rock Springs, Wyo.; G. S. Hoad, Ely, Nev.; L. F. Rich, Salt Lake City, Utah; C. N. Crain, Cheyenne, Wyo., and H. B. Rector, San Francisco, Cal.

Milwaukee Dealers on Business Boosting Tour

MILWAUKEE, WIS., Aug. 12—Fifty-five cities and twice as many villages will be visited by the second annual booster tour of the Milwaukee Automobile Dealers' association, which starts at Milwaukee on Monday, Aug. 28, and ends at Milwaukee on Saturday, Sept. 2. Gov. E. L. Philipp and Mayor D. W. Hoan of Milwaukee, will accompany the tourists from start to finish.

The principal object of the tour is to advertise the Wisconsin State Fair at Milwaukee, Sept. 11 to 16, and the motor show to be conducted by the M. A. D. on the fair grounds. A total of sixty cars carrying 300 will be entered, it is anticipated.

Marmon transcontinental car which was sealed by the A. C. A. for checking and identification

Fifth Industry in Indiana

86,500 Automobile, Body and Parts Plants in State—7219 Wage Earners in 1914

NEW YORK CITY, Aug. 15—Eighty-six automobile, body and parts factories in Indiana employed an average of 7219 wage earners in 1914, paid a total of $5,027,000 in wages, spent $18,830,000 for materials and turned out products of a total value of $29,390,000 during that year, according to a preliminary report furnished by the Bureau of the Census to the National Automobile Chamber of Commerce.

In 1904 there were only eleven establishments, employing 816 wage earners and turning out products valued at $1,639,000. Five years later (1909) the establishments had increased to sixty-seven, employing 6797 wage earners and producing $23,764,000 worth of cars, parts and bodies.

Thus, in 1904 the average value of the product was $2000 per man and $149,000 per factory. In 1909 it had risen to about $3500 per man and $354,000 per factory. In 1914 the average output was $4071 per man and $341,770 per factory.

Only four other industries in the state ranked higher than the automobile industry in number of men employed, in wages paid and in cost of materials used, while five ranked higher in value of output. Probably the automobile business has forged still nearer the top in the year and a half elapsed since the census year.

The accompanying table shows the standing of the nine leading industries of Indiana:

Commissioner Finds Gasoline Pumps Short

BOSTON, MASS., Aug. 12—More than one-fifth of the gasoline pumps measured in Boston do not give full measure. Thure Hanson, Commissioner of Weights and Measures of Massachusetts, has started his inspectors on a State wide tour of inspection of the various gasoline pumps used in measuring the fluid out to motorists. There have been vague rumors that some of the pumps were not as accurate as they might be, and so Mr. Hanson sent for his corps and told them to start work at once.

The first places visited were the Allston section of Boston, which is the very end of the motor district. From there the inspectors will work their way in town. After the first week of tests Mr. Hanson said he found that the pumps were varying in measurement. There were 178 pumps tried out. Of that number 42.7 per cent were correct. There were 33.7 per cent giving long gallons and 23.6 per cent were not giving full measure.

The inspectors tested each pump from two to five times so that there could be no charge of hasty decisions. The largest shortage found was eight gills or 5 per cent in 5 gal., while the largest excess was 36 gills or 22.5 per cent in the same amount. The inspectors said that it appeared that the public were getting full measure.

Garage Labor Prices Higher in Wis.

MILWAUKEE, WIS., Aug. 12—Practically every garage and repair shop in Milwaukee not identified with agencies have raised prices charged for labor from 65 cents an hour to 75 cents for mechanics and from 30 cents to 40 cents for helpers' time. The increase is one of the effects of the better business policy resulting from the organization of the Wisconsin Garage Men's Association by Milwaukee garage keepers during recent months.

Nearly all agency service stations still keep in effect the old price of 65 cents an hour for labor, but it is stated that an increase may be expected at any time because the workmen are demanding increased pay and shorter hours. Some of the agency garages which have capacity to accept work on cars other than they handle, have increased prices, but continue to charge 65 cents to customers.

LEADING INDUSTRIES OF INDIANA

Industry	Establishments	Wage Earners	Value of Product	Per Cent Increase in Five Years
Iron and steel	19	11,106	$58,883,000	52.3
Slaughtering and meat packing	68	4,484	51,066,000	8
Foundry and machine shop	513	17,025	48,881,000	23.1
Flour and grist milling	512	2,281	37,488,000	—7.1
Liquor distilling	14	3,824	31,484,000	—0.4
Automobile	86	7,219	29,390,000	23.7
Carriage and wagons	193	7,306	21,569,000	—0.4
Railroad cars	10	5,800	21,570,000	127

Industry	Wages Paid	Cost of Materials	Output Per Factory	Output Per Man
Iron and steel	$9,620,000	$27,057,000	$3,099,100	$5,302
Slaughtering	2,498,000	46,295,000	750,970	11 388
Foundry	10,790,000	21,340,000	95,284	2,871
Flour milling	1,289,000	32,241,000	73,218	16,435
Liquor distilling	336,000	5,006,000	2,248,857	8,233
Automobile	5,027,000	18,830,000	341,770	4,071
Carriage and wagon	4,386,000	10,725,000	111,278	2,952
Railroad cars	3,981,000	13,711,000	2,157,000	3,719

NOTE—Decrease from 1909.

Texas Crops Promise Prosperous Year

Record-Breaking Prices for Cotton Bring $100,000,000 Increase

AUSTIN, TEX., Aug. 12—Good crops and high prices for the products of the farms and ranches mean much to the motor car trade of Texas. Money from the sale of this season's crops is beginning to circulate and the benefit that it is having on all lines of business is already apparent. Cotton-picking will have become general by the middle of August. The bales that have been marketed up to this time brought record-breaking prices, and it is expected that the market will continue its present high level during the remainder of the season. This season's prospective crop of 4,200,000 bales will bring an increase of more than $100,000,000 over the returns of the preceding year.

While the forage crop is not as large as last year, it is being utilized to much better advantage and profit by reason of the fact that there has been a great increase in the number of silos. In western Texas the maize crop will go above 75,000,000 bu., which is a considerable increase over last year's yield. It is only within the last few years that the threshing of maize has been carried on to any great extent in this State. Under the general head of maize are included Kaffir corn, feterita, milo maize, cane and other varieties of sorghums. This grain is now regarded as one of the staple crops of Texas and the demand for it has spread to remote parts of the United States and to foreign countries. It usually sells for about the same price as corn.

Garden and Orchard

In the matter of fruits, vegetables and melons, the returns from these crops have been larger this season than was ever before known. It is estimated by traffic officials of railroads that the total shipments of onions, new potatoes, sweet potatoes, tomatoes, cabbages, lettuce, cauliflower strawberries, cantaloupes, watermelons and peaches will have reached 25,000 carloads by the end of the year.

Livestock interests are unusually prosperous. Stock farming and dairying are being carried on much more than they were a year ago.

1916 Texas Crop Estimates

	1915	1916
Cotton (bales)	3,322,480	4,200,000
Cotton (price)	$225,000,000	$326,000,000
Wheat (bu.)	22,862,000	12,000,000
Corn (bu.)	175,075,000	165,000,000
Oats (bu.)	44,375,000	12,000,000
Rice (bu.)	7,113,000	10,000,000
Maize (bu.)	.....	75,000,000

Ford Salesmen Form Agencies

Some of the Large Cities Have as Many as Twelve New Ford Stores

NEW YORK CITY, Aug. 15—Salesmen in the Ford retail branches will not be cast adrift upon a cold world. Many will be better off than heretofore. Advices from leading cities state that they are forming partnerships and agencies to sell Fords and will thereby be able to profit by their previous experience. There will be eight agencies in Cleveland and in St. Louis ten. Some of the salesmen will get jobs with their former co-workers who now become dealers.

—

Baltimore's Twelfth Ford Agency

BALTIMORE, MD., Aug. 15—Ford agencies are springing up all over Baltimore despite the fact that the Ford company opened a factory branch here on Aug. 1 at 10 to 20 East North Avenue.

E. T. Backus, Ford local manager, declined to make any statement on what the sub-agencies all over town meant. He refused to discuss the matter at all.

It is known that the various members of the retail sales force that was organized by the local factory branch have joined together in pairs and are establishing agencies. The Ford headquarters will no doubt be continued as a big distributing force and a force of mechanics is working hard on alterations.

Wilcox & Brown, two of the best known Ford salesmen in the city, have opened an agency at 607 West North Avenue. R. M. Stein, who has been handling the Moon agency, has opened a Ford store. Another Ford agency opened to-day at Baltimore and Eutaw Streets and will be known as the Ford Agency Co. It is expected that there will be at least a dozen retail Ford agencies in the city. About 2500 Fords were sold in Baltimore last year, and under the present plan it is estimated that the number will be doubled.

Ford to Drop Retail Sales

(*Continued from page* 255)

is available, but in all probability the minimum allotment will be ten cars.

It is thought that the new method will greatly reduce the garage and service cost to the ultimate user of the cars, although the plan is not yet old enough for any predictions of this kind to be made. Economies all along the line resulting from the new scheme might suggest ways and means of lowering the cost, but these are yet to be proven.

In the sense that any reputable concern will be able to get a supply of Fords at a Ford branch, any big users of cars, even though these machines be for his own business, can get them direct, providing he wants enough to come within the minimum wholesale requirements. In other words, if a big department store wanted ten or twenty-five cars for its own delivery system it could go direct to the Ford branch and secure them at wholesale prices without going through a dealer. If this same concern wanted less than the minimum wholesale allotment it would have to buy them through any Ford seller and pay retail prices. It could not get this less-than-minimum number through the Ford branch.

Already in all parts of the country evidences of the new Ford selling method are to be noted. In Detroit several organizations either have been formed or are in the process of formation to sell the cars with no territorial restrictions. They will give recognized Ford service and maintain a Ford garage. The branch here will eventually close its doors to the retail buyer of cars.

—

Denver Ford Increases 150%

DENVER, COL., Aug. 12—During the first 6 months of 1915 the Denver plant assembled 2618 cars, while during the first 6 months of 1916 it turned out 6863 cars. In addition to this output the factory shipped 1400 cars into this territory during the 1916 period for the reason that the local branch could not get materials fast enough to supply the immediate demand.

Other leading cars show sales increases ranging from 50 per cent to as high as 300 per cent for the same comparative period, and several distributers claim that they could have done a still larger business this year if prompt deliveries had not been hindered by a serious shortage of cars.

Returns for the first half of this year show a total registration of more than 34,000 cars for Colorado alone, as against a total of not quite 22,000 for the same period last year and about 28,000 for all of 1915. This gives a registration increase of 54 per cent for the half-year period, or 21 per cent over the year.

Crow Elkhart Much Larger

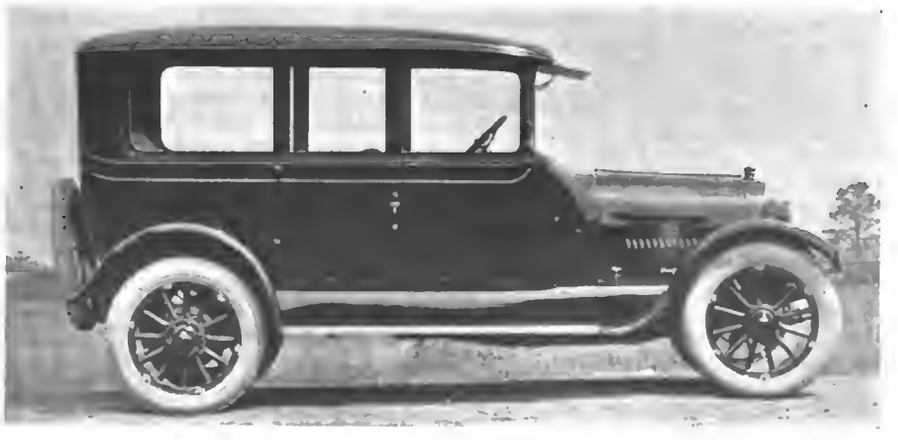
New Touring Body Very Spacious—Appearance Improved —Cloverleaf Continued

ELKHART, IND., Aug. 15—A larger touring car of improved appearance is now being produced by the Crow Motor Car Co., this city. It sells for $795 and is claimed to be one of the largest cars selling for less than $1,000. The chassis is much the same as the 1916 model, the only change being in the wheelbase, which is now 114 in. instead of 112. This increase has allowed 3 in. more length in the tonneau, and the manufacturers state that there is now sufficient space to permit the fitting of two auxiliary seats in the tonneau without cramping the rear seat passengers. The rear seat is widened to 49 in., the body bulging slightly over the wheels and thereby making a very neat junction with the curves of the new domed fenders. There is also a new radiator with a neatly rounded outline and the hood tapers smoothly into the body, the side lines from tip of radiator to the back seat line being almost dead straight. The cloverleaf roadster body which the company has been building for several months is now fitted to the same chassis as the touring car, but has not been changed in any way, the slightly pointed radiator and flat fenders being retained for this model.

—

Winningham Hudson Advertising Manager

DETROIT, MICH., Aug. 14—C. C. Winningham, who is sales manager and director of advertising of the Hudson Motor Car Co., has now taken full charge of the advertising department, since W. L. Agnew, who was advertising manager, resigned. Owing to the growing importance of the advertising department, Mr. Winningham will devote considerably more time to it than heretofore.



New Reo Sedan which has been put out on the standard chassis

General view showing roadway up Pike's Peak Mountain from a point near the summit. The distance of the hillclimb was 12.5 miles, the maximum grade 10½ per cent, and the average grade 7½ per cent. The sinuous nature of the course is well indicated

Hudson, Chalmers Win at Pike's Peak

Romano Takes Penrose Free-for-All Trophy in Long Climb

COLORADO SPRINGS, COL., Aug. 12—Rae Lentz, Ralph Mulford and Fred Junk, driving respectively the Romano, Hudson Super-Six and Chalmers, divided honors in climbing Pike's Peak during the 2-day motoring festival that ended here to-day. It was predicted before the events took place that the winner's time in each of the three events would be close to 15 min.; but the prognosticators did not take into consideration several factors, among which were the weather, carbureter troubles and proper gearing.

Two events were run yesterday, one for cars of 231 cu. in. displacement and under and one for cars with a displacement ranging from 231 to 300 cu. in.

Six cars were entered in the 231 to 300 cu. in. event. These were sent away in two groups, the first including Hughes, Mulford, Parish and Oldfield, and the second Buzane and Patterson. Hughes went out in his car above timberline with motor trouble, and a faulty timing device made it necessary to recall Oldfield and Parish after they reached Glencove, as their time at the start was not registered. This left the course free for Mulford, and he covered the 12½-mile course in 18 min. 24.7 sec. The maximum grade is 10½ per cent; average 7½.

Sending two cars back put four in the second group to start, and Patterson's Hudson seemed to have second place cinched but ran off the course when about 20 ft. from the finish line and was disqualified. This left Buzane, in a Duesenberg, second and Parish, in a Mercer, third, as Oldfield's Delage did not do anything spectacular. In fact, Barney did not get his car on the course until the morning of the race.

To-day's event, which was for the Penrose trophy and $3,000 in cash, was won by Rae Lentz in a Romano special having an eight-cylinder aeroplane motor with a displacement of 402.12 cu. in. Ever since Lentz began to perform on the course he was predicted to be a likely winner, but his time to-day was not equal to that shown by Mulford in winning yesterday's event; but, of course, physical conditions were different to-day, for most of the race was run in rain, sleet and snow. Mulford finished second in to-day's race, and he, too, found climbing more difficult to-day.

Conditions were anything but auspicious for to-day's event. Most of the climb was through a driving storm of rain, hail and snow, and the spectators, who journeyed far up the mountain to watch the drivers zigzagging far below them, shivered in the cold. Goggles worn by the racing crews were so covered with rain and sleet that they had to be discarded.

Race Tabulation

PENROSE TROPHY EVENT

St. Louis A. C. Holding October Tour

ST. LOUIS, MO., Aug. 12—The Automobile Club of St. Louis will hold its three-day tour for owners early in October. The trip will embrace Keokuk with a night stop at Lousiana, Mo.

United Motors Corp. Ramifications

Big Cog in Industry Serves 10,318 Companies and Turns Out 28,323,000 Parts

NEW YORK CITY, Aug. 15—The magnitude of the automobile industry and its various ramifications has been brought out in an article appearing in the *Wall Street Journal* which takes up one of the large units, the United Motors Corp. showing the large production and the service given by this one cog in the industry.

The United Motors Corp. serves with its products 10,318 companies, and every automobile in use is equipped with one or more of its products. The output, consisting of 28,323,000 parts annually, may be classified as follows:

	Daily	Annually
Anti-friction bearings	65,000	19,500,000
Coaster brake hubs	1,800	540,000
Starting, lighting and ignition systems	1,150	345,000
Ignition systems only	1,450	435,000
Demountable rims	25,000	7,500,000

The Delco system was installed last year on 142,500 automobiles. Orders have been received thus far this year for approximately 200,000 and additional orders of 50,000 are expected before the end of the season. As of July 15 there were approximately 500,000 Delco-equipped automobiles in service.

More than 7,500,000 Hyatt bearings were supplied for automobiles in the 1916 season and over 10,000,000 bearings, it is estimated, will be required for the 1917 production. Of approximately 1,000,000 cars built this year Hyatt bearings are a part of more than 925,000.

The New Departure company had a daily production in Mya of 14,800 bearings, 1800 coaster brake hubs and 1,500,000 balls. The output has been steadily increased since that time, and by next Spring an output more than double the preceding figures is expected.

The Perlman Rim Corporation turned out daily in June 2000 sets of rims, or 10,000 individual rims. The production by Oct. 1 is scheduled at 5000 sets a day.

The fifth company in the United Motors organization is the Remy Electric Co., which is at present turning out over 950 ignition systems, composed of ignition distributers and magnetos, 400 generators and 350 starting motors. This production will be increased 30 per cent within 6 months and the output for the year will reach the record mark of 410,000 ignition systems and 125,000 starting and lighting outfits.

All of these products are manufactured in 110 buildings with an aggregate floor-space of 2,449,229 sq. ft. The number of employees is 14,000.

Six Entries for Harvest Meet

INDIANAPOLIS, IND., Aug. 12—The fourth entry for the three events in the Harvest meet at the Indianapolis Motor Speedway on Sept. 9 adds an international touch. Josef Christiaens is the first foreign driver to enter the 20-, 50- and 100-mile events on the program and he will drive the English Sunbeam in which he has made a name for himself on the various tracks of America, as well as in foreign countries.

The car is the same which raced first in New York last spring. Gil Anderson and Howard Wilcox, entered by the Speedway Team, will drive their Premier cars.

The Sunbeam brings the total to six cars entered in the Sept. 9 event. Two Peugeots, with Aitken and Merz at the wheels and the Ostewig Special with S. Ostewig driving, are the other entries received by General Manager, T. E. Myers, of the Speedway.

Speedway Company in Columbus

COLUMBUS, OHIO, Aug. 12—The Columbus Motor Speedway & Horse Racing Co., has been incorporated with an authorized capital of $200,000 for the purpose of building a speedway for both automobile and horse races. The incorporators are: T. M. Hardesty, S. B. Randall, S. D. Maddox, L. F. Laylin and Robert Pfeiffer.

Fourteen Entries for Chicago Speedway

Resta, De Palma and Other Major Lights of Racing World to Participate

CHICAGO, ILL., Aug. 15—When the elimination trials open to-morrow, fourteen cars will attempt to qualify for the American Speedway Grand Prix race to be held here next Saturday. These trials will continue Thursday and Friday, and it seems probable that from past performances of the majority of the entry list, the requisite speed of 100 m.p.h. will be attained, and that when the cars are lined up before the starter at 2 o'clock next Saturday afternoon, the total number to participate will be practically the same as the entry list.

Entries to date include two Packards, one of which has been entered by Ralph De Palma, along with his Mercedes, and it is not known at present whether Ralph will enter the race next Saturday driving a Packard, or the car which has served him both well and uncertain in various races for several years—the Mercedes. This leaves one Packard with the driver un-named.

Dario Resta's Peugeot is here, and he is expected to arrive to-day. The Hoskins Special, which Eddie O'Donnell drove at Kansas City, will be driven by George Buzane, as O'Donnell's broken arm is not healed sufficiently to allow him to participate. Ralph Mulford has wired his entry of the Peugeot and the Hudson Super Six. The latter he is bringing to Chicago from Colorado Springs, and the Peugeot is being shipped here from New York.

Among the other entries are: D'Alene's Duesenberg, Milton's Duesenberg, Christiaens' Sunbeam, and Galvin's Sunbeam, Jackson's Ben Hur, Lewis Chevrolet's Frontenac, and another Hoskins Special, to be driven by Eddie Rickenbacher, this car being a duplicate of O'Donnell's car and owned by C. C. Hoskins.

Fred Junk in the winning Chalmers at the Pike's Peak Mountain hillclimb and Mulford in the record-breaking Hudson

Security Prices Are Higher

General Motors Features with 70 Points Gain—Chevrolet Up 25 Points

NEW YORK CITY, Aug. 15—Automobile and accessory securities last week regained their prestige on the Stock Exchange and Curb Market by again becoming one of the strongest group of stocks. Most all of the stocks advanced under the stimulus of buying orders from a group of stock exchange houses. General Motors was especially strong, and rose to a new high record during the middle of last week to 583. Rumors have it that this company will soon cut another large melon. Just what effect these rumors had with the rise of this stock is not known, but the other stocks were seemingly affected by the increase and joined in with substantial gains. Chevrolet, with the aid of buying orders from the houses showed some of its old-time vigor and advanced sharply with increased strength. Rumor has it that this company will declare a large cash dividend. Stutz, United Motors, and Stromberg, were also prominent on the curb. Stutz showed a new high level of 66, a gain of 2⅝ points. United Motors was bouyant, in sympathy with the movement in Chevrolet.

Other securities to make substantial gains were Goodyear common, 10 points; Saxon, 4½ points; Studebaker common, 3¼ points; U. S. Rubber common, 2⅛; and Willys-Overland common, 2 points.

The quotations on the Detroit Exchange were also higher with General Motors featuring with a 60 point rise on its common. The rest of the gains ranged from 1 to 10 points.

—

15 Per Cent Dividend for Bower Roller

DETROIT, MICH., Aug. 14—As evidence of the prosperous condition of the Bower Roller Bearing Co., manufacturer of the Bower roller bearing, the stock of the company was placed on a 60 per cent dividend basis at a recent meeting of the board of directors. In other words, a dividend of 15 per cent was declared and it was styled a quarterly disbursement.

—

West Canadian Provinces Buy 8,000 Cars

WINNIPEG, Aug. 9—Eight thousand cars have been sold this year in the three provinces of Manitoba, Saskatchewan and Alberta. Of this quantity 3500 were taken by Manitoba. Local dealers assigned the improvement through the success of an exact road building campaign initiated by the government.

—

Dallas Dealers Plan Fall Show

DALLAS, TEX., Aug. 9—Plans for an automobile show during the state fair, Oct. 14 to 31, were practically completed at a meeting held to-day by nearly all of the dealers of this city.

Copper Prices Are Higher

Up to 27 Cents a Lb.—Open-Hearth Steel Higher—Further Drop in Petroleum

NEW YORK CITY, Aug. 15—The rise in copper and open-hearth steel and the decline in petroleum featured in last week's market activities ih this city. Copper is again showing unusual activity and as a result prices have gone up in both lake and electrolytic to 27 cents a pound, a gain of ¼-cent. Crude oil prices have gone down 15 to 30 cents a barrel during the past two weeks. It is stated that further reductions will be made. Kansas petroleum is now quoting at $1.05 while Pennsylvania is down to $2.35. The gasoline situation in this city, despite the general reduction in crude oil prices, is steady, and competition is keen.

Lead was active and in demand, with quotations 5 cents a pound higher yesterday. Tin also was active again on the resumption of buying and rose to $39.50 per 100 lb., a net gain of $1.75 for the week. The rest of the metals were steady.

The rubber market was quiet with Up-river Para steady at 65. Ceylon grades fluctuated throughout the week, reaching 58½ cents and then declining to 57½. The Intercontinental Rubber Co., Tucson, Ariz., has started experiments to make cheaper rubber.

Maxwell Common on 10% Basis

Initial Dividend Declared—Dividends of $7 and $6 on First and Second Preferred

NEW YORK CITY, Aug. 15—The Maxwell Motor Co., Detroit, Mich., to-day declared an initial quarterly dividend of $2.50 per share on the $12,778,050 in common stock, payable Oct. 2 to holders of record Sept. 11. This virtually places the issue on a 10 per cent per annum basis. The company also declared a dividend of $7 per share on the $12,816,400 first preferred and $6 a share on the $10,127,468 second preferred.

The dividend on the first preferred is payable in four equal quarterly installments of $1.75 each, as follows: Oct. 2 to holders of record Sept. 11; Jan. 2, 1917, to holders of record Dec. 11, 1916; April 2, 1917, to holders of record March 10, 1917, and July 2, 1917, to holders of record June 11, 1917.

Second Preferred Dividend

The second preferred stock dividend will also be paid in four equal quarterly installments of $1.50 each, as follows: Oct. 2, 1916, to holders of record Sept. 11, 1916; Jan. 2, 1917, to holders of record Dec. 11, 1916; April 2, 1917, to holders of record March 10, 1917, and July 2, 1917, to holders of record June 11, 1917.

President W. E. Flanders, after the meeting of the directors, stated that the company had enjoyed a most prosperous year and now has 80,000 cars of the 1917 type contracted for.

Sales of Maxwells during July were about 7000 cars, and it is expected that the output will run 8000 for August. Very likely the company will figure on a manufacturing schedule of 100,000 cars for the coming fiscal year.

Of the 60,000 cars manufactured last year, about 3000 were for export. Surplus earnings for the fiscal year ended July 31 last were over $5,000,000 after deduction of all charges of every character.

90,000 People See Ford Tractors

(*Continued from page* 255)

handling two plows; that is, plows two furrows at once. The tractor is not on the market yet and will not be ready until next year, when the factory of Henry Ford & Son, Dearborn, Mich., is expected to be under operation. The present demonstration here was apparently made with the object of trying out public sentiment and getting general criticisms. The few criticisms heard were to the effect that some changes will have to be made; but if Ford had been able to make deliveries he could have gone back to Dearborn with scores of orders and cash on deposit in his pocket.

The 3 days of demonstrations here were the greatest compliment to motor power for farm use that could be wished for. Never before has such enthusiasm been seen, and while the name of Ford naturally exerted its magnetism, yet there were thousands and tens of thousands who came to see the other threescore tractors demonstrate their superiority over fast-fading Dobbin.

The total attendance of 90,000 for 3 days, two of which were muddy, compares favorably with the attendance for a week at the Grand Central Palace motor show in New York or the Coliseum show in Chicago. With good weather and a week's show the tractor demonstration would prove itself a giant.

It is a sight to inspire the heart of man to see sixty-five motor tractors operating at the same time. The appetite for performance of these new gasoline-eating machines is nothing short of prodigious, for they plowed 160 acres of land in 2 hr. At this pace a farmer owning a whole section of land 1 mile square (640 acres in all) could have his entire block plowed between breakfast and afternoon tea, and have time for an hour at lunch.

Tractor manufacturers exhibited at Fremont to a greater extent than at the earlier demonstrations, both because there were more of them ready and because the Fremont demonstration has come to be recognized as the classic. There were forty different makes of tractors to be seen, and at least one-half of the makers had two or more models on display.

The 3 years of tractor demonstrations at Fremont has had its effect on the attitude of the farmers of that section. They do not have to be shown that the farm tractor as a piece of farm machinery is a practical and successful thing. Their neighbors have been using them, and have produced better crops by the deeper plowing made possible by the tractors. Three different farmers, one of whom lived 75 miles away from Fremont, pointed out to me a field upon which the demonstration tractors had operated the two preceding years and which this season produced a yield nearly double that of its horse-plowed neighbors. "Deeper plowing," was their explanation.

As to the fuel situation the tractor makers seem to be quite divided. Approximately one-half of the tractors in the field were operating on kerosene. To make sure that there was no false claims in this regard the technical committee tested the fuel used in the plowing demonstrations. Nevertheless some of the tractor men who favored gasoline impressed one with their doubts as to the real nature of the fuel used by the kerosene burners.

All of the tractors, in fact, were exceptionally free from stoppages due to mechanical troubles. With one or two exceptions all the machines dug in and finished up their task in a steady and businesslike way that was an eye-opener to the novice in tractordom.

Prospects

The marketing of agricultural tractors differs from the marketing of motor cars in one essential respect. If a farmer, or any other man for that matter, has sufficient of worldly goods to buy and main-

Jones Federal Brass Sales Manager

DETROIT, MICH., Aug. 16—Lloyd P. Jones has been made sales manager of the Federal Brass Works, Detroit.

For the past five years Mr. Jones has been connected with the American Bronze Company, and since 1913 has been manager of their western office.

Three Gallons Just As Dangerous

ST. LOUIS, MO., Aug. 12—Pouring 3 gal. of gasoline on the street is as dangerous as pouring any larger quantity in the opinion of Mayor Kiel, who has just vetoed a bill prohibiting the pouring of more than 3 gal. of gasoline on the street.

The new Ford tractor at the Fremont, Neb., tractor demonstration. It is a four-wheel design using a four-cylinder motor 4 by 4¼, multiple-disc clutch, three-speed and reverse, constant-mesh type of gearset and worm-drive to the rear axle. It weighs less than a ton. The price has not yet been set. It pulls two plows at a speed of 2 to 2½ m.p.h., and will travel at 5 to 6 m.p.h. on the road

tain a motor car he is considered at least a possible prospect. But when it comes to buying a tractor for tilling his fields there enters another consideration, and that is, "Will it pay?"

The answer to this question involves a number of considerations, but the chiefest of these, particularly in level country, is the tillable acreage.

The Department of Agriculture has found that, in general, on level land a tractor will pay, if properly managed, when the tillable acreage is not less than 160 acres. According to Nebraska real estate men who have been in touch with conditions in this territory for years, the average size of the farms in Nebraska is double that figure. There are, of course, many farms of 160 acres or less, but there also are many in which the acreage is 1000. It is on the larger farms that the tractors have been operating for the greatest period and with the most success.

One landowner whose holdings approximate 1200 acres of corn and wheat lands has been operating two very large tractors for several years and this week purchased two smaller ones to use in addition to his larger ones. To a certain extent it is the smaller capacity and less expensive tractors that are popularizing these machines in this territory. A big, heavy, expensive machine capable of pulling eight or ten 14-in. plows represents too much capital to the owner of 240 or 360 acres, and its capacity is so great that there is not work for it on one farm a sufficient proportion of the time. It has been found, as a general rule, that to keep the machine sufficiently busy by doing custom work on other farms is not a paying proposition.

The later types of smaller, lighter and less expensive tractors capable of handling two to four plows seem, in the opinion of a large proportion of the farmers in the territory, to meet the demands of the moderate-size farm, and with many of them the purchase of a tractor depends on present prosperity and future crop prospects.

General view of tractor demonstration at Fremont, Neb., last week

The August crop report for the State of Nebraska as compiled by the federal bureau of crop estimates Aug. 1, together with the actual production last year, is given below. It should be borne in mind that last year's production was approximately 120 per cent of the normal yield for the past 5 years; also, that this estimate was made before the general rains of this week, which put hundreds of thousands of dollars in the pockets of the Nebraska farmers and, in the minds of some, meant a full corn crop instead of a partial one.

Crop	Aug. 1, 1916 (Estimate) Bushels	1915 Production Bushels
Corn	180,000,000	213,000,000
Winter wheat	61,600,000	66,618,000
Spring wheat	4,560,000	5,536,000
Oats	75,100,000	70,400,000

Fremont markets Aug. 9, 1916, quoted No. 2 wheat at $1.30, No. 3 corn at $0.75 and oats at $0.35 per bushel. On Aug. 1, 1915, wheat was 29 cents less, corn 5 cents less and oats the same. Live stock and dairy products last year put $244,000,000 in the coffers of the Nebraska farmer and this year will do as well.

There has been a great deal of discussion among tractor men as to whether the motor car dealer or the implement dealer is the logical man to handle tractor sales. A new argument was injected into the discussion to-day by the representatives of two big tractor makers who, by the way, also are large manufacturers of other farming implements. They made the point that the question is one which necessarily will solve itself, because the implement man who handles tractors will find it to his advantage to handle motor cars as well, and, on the other hand, the motor car dealer who takes on a line of tractors must perforce stock up with plows, harrows, disks and the other implements which are to be drawn by the tractor. In other words, the car-tractor dealer will become an implement man and the implement-tractor dealer will become a motor car man.

Factory Miscellany

Bell to Build—The Bell Motor Car Co., York, Pa., is planning a one-story, 108 by 240-ft. plant.

Alter Starts Building—Excavation has been begun at Grand Haven, Mich., for the new factory of the Alter Motor Car Co.

Michelin Tire to Add—The Michelin Tire Co., Milltown, N. J., has let a contract for the erection of a one-story, 25 by 46 and 23 by 780-ft. addition.

Chicago Parts Co. Builds—The Regal Model & Tool Works, 122 South Clark Street, Chicago, Ill., is building a plant for manufacturing special machinery, automobile parts and dies.

To Make Washing Device—The Keystone Device Co., Harrisburg, Pa., has established a plant for the manufacture of a patented automobile washing device composed of a brush and nozzle.

Buys Tractor Plant—The plant of the Ohio Tractor Mfg. Co., Marion, Ohio, has been purchased by W. H. Houghton and associates of Marion. It will be used for the manufacture of commercial vehicles.

Gordon Plant Ready by Sept. 1—The L. O. Gordon Mfg. Co., Muskegon, Mich., a new concern which will make camshafts and other automobile specialties, is expected to have its plant in full operation by Sept. 1.

Springfield Body Moves Ad and Sales Departments—The Springfield Body Co., Springfield, Mass., has moved its advertising and sales departments from the Springfield factory to 509 David Whitney Building, Detroit, Mich.

To Make Engines—The Field Motor Co., Grand Rapids, Mich., has practically completed negotiations for the erection of a plant for the manufacture of a new process gasoline and kerosene engine. It will be one story, 50 by 100 ft.

Dewes Plant Moved—The plant of the A. Dewes Co., maker of stampings, dies and automobile accessories, will be moved from its present location, 241 Centre Street, New York City, to 199 Lafayette Street. This change in location was made necessary by the business outgrowing the present quarters.

Wald Machine to Add—Ground was broken to-day by the Wald Machine Co., Sheboygan, Wis., a large producer of accessories and mechanical specialties, for its new shop building, 80 by 100 ft. in size. When completed, the new shop will make it possible to increase the production nearly 300 per cent.

Miller Plant Enlarged—The plant of the Harry A. Miller Manufacturing Co., Los Angeles, Cal., has been enlarged and remodeled. A large addition has been taken over, in which the pattern shop, motor and racing departments are located. In addition to turning out fifty carbureters a day for the Miller Carbureter Sales Corp., the factory is building motors, including a twelve-cylinder aviation motor for De Lloyd Thompson, which is to weigh less than 800 lb. and develop 300 hp. at 1400 r.p.m. As a great many of the racing drivers make headquarters at the Miller plant, there is now a department given over entirely to them, where their cars are kept and where they have all the machinery.

More Metal Workmen Wanted—The Western Malleables Co., Beaver Dam, Wis., which recently established a separate division for handling a large influx of business from the automobile industry, is combing the country in search of additional help. Last week a party of fifty skilled molders from Portland, Ore., arrived at the plant in response to the insistent call directed at the Pacific Coast, where labor conditions are said to be less serious than in the Middle West. The Beaver Dam Co. could use 250 to 300 more men to man its foundries, consisting of three large units in Beaver Dam.

The Milwaukee branch assembling plant of the Ford Motor Co. now has reached a daily production of 106 cars and before Sept. 1 expects to increase this number to 150. The shortage of skilled labor, which is keeping down the production of all metal working shops in Milwaukee, has affected the Ford works.

The Automobile Calendar

ASSOCIATIONS

Aug. 28-Sept. 1 — Milwaukee, Wis., Booster Tour of Milwaukee Automobile Dealers.

Sept.— Indianapolis, Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.

Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.

Oct. 13—Flint, Mich., Fall Meeting National Assn. of Automobile Accessory Jobbers.

Dec. 2-9—Electricians' Country-wide Celebration.

CONTESTS

Aug. 18-19—Elgin Road Race, Chicago Auto Club.

Aug. 26—Kalamazoo, Mich., 100-Mile Track Race.

Sept. 1-2—New York, N. Y., Sheepshead Bay Speedway, 24-Hour Race, Trade Racing Assn.

Sept. 4—Elmira, N. Y., Track Race, Elmira Auto and Motorcycle Racing Assn.

Sept. 4—Cincinnati, Ohio, Speedway, Cincinnati Speedway Co.

Sept. 4—Newark, N. J., Track Race, Olympic Park, Racing Assn.

Sept. 4—Des Moines Speedway Invitation Race. Limited to six entries.

Sept. 4-5 — Spokane, Wash., Track Race, Inland Auto Assn.

Sept. 9—Indianapolis Speedway Race.

Sept. 16—Providence Speedway Race.

Sept. 18—North Yakima, Wash., Track Race, Washington State Fair.

Sept. 29—Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.

Sept. 30 — New York City, Sheepshead Bay Speedway Race.

Oct. 7—Philadelphia Speedway Race.

Oct. 7—Omaha Speedway Race.

Oct. 14 — Chicago Speedway Race.

Oct. 19—Indianapolis, Ind., Race, Indianapolis Motor Speedway.

Oct. 21 — Kalamazoo, Mich., Track Races, Kalamazoo, Motor Speedway.

Oct. 22-23—Los Angeles, Cal., Commercial Car Reliability Tour.

Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

GOOD ROADS

Sept. 1-9—Cincinnati, Ohio, Good Roads Exposition and Convention, Music Hall, Hamilton County Dixie Highway Council of Cincinnati.

Sept. 6-7—St. Paul, Minn., Good Roads Congress, Auditorium.

SHOWS

Aug. 7-19—Atlantic City, N. J., First Show, Young's Pier.

Sept. 2-9—Cleveland, Ohio, Show, Industrial Exposition and Fair, Edgewater Park.

Sept. 2-9—Columbus, Ohio, Fall Show, Ohio State Fair, Columbus Automobile Show Co.

Sept. 4 - 8 — Hartford, Conn., Show, Connecticut Fair Assn.

Sept. 4-11 — Indianapolis, Ind., Show, Indiana State Fair, Indianapolis Automobile Trade Assn.

Sept. 10-16 — Milwaukee, Wis., Show, Wisconsin State Fair, Machinery Bldg.

Sept. 25-30—Salem, Ore., State Fair, Joseph M. Rieg, manager.

Oct. 14 - 31 — Dallas, Texas, Show, State Fair.

Sept. 11-16 — Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.

The Week in the Industry

Southwest Items—S. S. Lindsey, sales manager of the Kansas City branch of the Buick Motor Car Co., has been promoted to manager of the branch at Oklahoma City.

The Ramsey Auto Co., Kansas City, Mo., has been organized to handle the Detroiter six. J. A. Ramsey is manager.

The Velie Motor Car Co., Kansas City, Mo., has purchased a lease on the southeast corner of Sixteenth and McGee Streets, and will erect a salesroom there.

Columbus News Items—The Peters & Heron Dash Co., located on Culbertson Street, Columbus, Ohio, has sold its dash and buggy business to the McKinnon Dash Co. of Buffalo and Troy, and will devote its attention in the future to the manufacture of automobile hood covers, robes, dimmers and other accessories, which has developed amazingly in the past few months.

R. W. Pharis, who has been connected with the Pharis Tire & Rubber Co., Newark, Ohio, in the capacity of secretary and manager of the Columbus branch, has resigned to take up the management of the International Tire Co., a new retail concern at 187 East Gay Street.

The Columbus Cadillac Co., central Ohio agents for the Cadillac, has taken a lease on the southwest corner of Broad and Sixth Streets upon which will be erected a 2-story building for sales headquarters.

Sales agents representing the Domestic Engineering Co., Dayton, Ohio, manufacturer of the Delco light systems, convened at the office of J. J. Munsell, general agent for central Ohio at the office of the agent, 11 East Rich Street, Columbus, recently. It was the first meeting of sales representatives held east of the Mississippi River. R. H. Grant, general manager of the company, was chief among the speakers. In all about forty sales representatives were in attendance. Reports of a very encouraging nature were made.

The Marion-Handley Sales Co. has been organized in Kansas City to handle the product of the company in eastern Kansas and western Missouri.

Russell H. Clark & Co., Kansas City, body and top builder, is building outing and commercial trailers, its specialty being the Russ outing trailer, convertible by removing the wire spring bed into commercial trailer. The firm is also stocking commercial bodies for touring cars; it is furnishing commercial cars complete.

S. R. Parsons, Kansas City, has established the Parsons Motor Co. for handling the Tonford unit 1-ton truck of the Detroit Truck Co. in Kansas and Jackson County, Mo. Mr. Parsons will equip a shop and salesroom shortly at 1804 Grand Avenue.

Pacific Coast News—E. A. Williams, Jr., president and general manager of the Garford and Gramm Motor Truck Co., has announced that the company will build a branch building in Seattle in the near future, which will be under the supervision of A. W. McKenzie, Pacific Northwest manager. Temporary offices and salesrooms have been opened at 1726 Broadway, which handle the business of the company in Washington, Oregon, Idaho, British Columbia and Alaska.

The North Pacific Oakland Company has been organized in Seattle to handle the agency for the Oakland car in Washington, Oregon and northern Idaho. R. K. Roberts, until recently assistant general sales manager of the Oakland Motor Car Co., with headquarters at San Francisco, will be general manager of the new company, and E. M. Mark, who has been at the head of the Northwest Oakland company, distributor of the Oakland cars for western Washington, will be secretary and treasurer.

The Pacific KisselKar Co., Pacific Coast distributor for the KisselKar and Briscoe lines, has opened a branch at 806 East Pike Street, Seattle. The company is now operating branch houses in San Diego, Pasadena, Los Angeles, San Francisco, Cal., and Portland, Ore.

B. C. Scearce has been appointed assistant manager of the northwest branch of the Metz Motor Car Co. in Seattle to succeed D. H. Hotchkin, who recently became factory representative of the company for its northwest territory.

The Northwest Buick Co., which recently took the agency for the G. M. C. trucks in the Pacific Northwest, announces the appointment of W. H. Barnes, formerly factory representative of the General Motors Truck Co., as truck sales manager. H. H. Harwood, formerly with Frederick & Nelson, has been appointed assistant sales manager of the truck department.

The Portage Tire Sales Co. has opened northwest distributing quarters at 706 East Pine Street, Seattle, to handle the agency for the Portage tire.

The Fisk Rubber Co. has moved into its new branch at the corner of Tenth Avenue and East Pike Street, Seattle.

Omaha News Tips—A direct factory branch for the Willys-Overland Co., under the firm name of Willys-Overland, Inc., has been opened here with J. R. Jamieson, president of the Overland-Omaha Co., in charge.

The old show rooms at 2047-2049 Farnam Street will be maintained, and in addition the company occupies the old quarters of the Ford Motor Sales Co. at Twentieth and Harney Streets, the latter moving to the new branch factory at Sixteenth and Cuming Streets, recently completed.

Henry Werdehoff, who has directed the mechanical department of the local house for two years past, will have charge of the service department in the new location.

The Overland Auto Co., Denver, for several years Overland distributor for Colorado and Wyoming, has given up this agency on account of the new Willys-Overland factory branch just established, and has secured the King and Saxon distributing agency for the same territory, with headquarters at 1200 Broadway. The concern will continue to operate under its established name, at least temporarily, with W. J. Carter as president and treasurer.

The Cole Motor Sales Co., Denver, is the name of a new Cole distributing agency for Colorado and Wyoming just opened at 17 East Colfax Avenue by H. P. Federspiel, formerly manager of the Colorado Motor Car Co.

The National Motor Co., Denver, National and Elgin distributor for Colorado, Wyoming and western Nebraska, has added the Weston distributing agency.

Stiermann Vehicle Co., St. Louis, has been appointed distributer in this community for the Aurora demountable truck attachment which converts a Ford chassis into a 2000-lb. truck.

Hudson Phillips Motor Car Co., St. Louis, has been named distributing agent for the Philadelphia Diamond Grid Starter batteries.

L. M. Ball has been made service manager for the Locust Motor Sales Co. of St. Louis, distributer of the Scripps-Booth car.

J. W. Angle of Wilcox, Ariz., has been appointed an agent for the Moon cars.

Monarch Auto Repair Co., St. Louis, has been appointed distributer for the compensating air plug.

The St. Louis Electrical Works, St. Louis, Mo., will shortly begin the erection of a two-story factory building at Sarah Street and Forest Park Boulevard.

VOL. XXXV NEW YORK—THURSDAY, AUGUST 24, 1916—CHICAGO No. 8

Consolidated Now Abbott Corp.

Moving from Detroit to Cleveland and Increasing Stock from $500,000 to $1,250,000

DETROIT, MICH., Aug. 21—The Consolidated Car Co., manufacturer of the Abbott-Detroit cars, has been reincorporated under the name of the Abbott Corporation, and the capital stock has been increased from $500,000 to $1,250,000. The larger stockholders in the concern are F. C. Hull and A. W. Gardiner of this city.

It has been definitely decided to remove the business of the Abbott Corporation to Cleveland, Ohio, where a factory has already been secured which will have ample facilities for the increasing of production over the fifteen to twenty-car-a-day output possible in the present factory here. Difficulties in getting materials and the labor situation here are given as two reasons for the change, although Messrs. Gardiner and Hull have material financial interests in Cleveland, according to M. J. Hammers, vice-president, and this move will, therefore, serve to group the holdings of those principally interested and provide the best of financial and commercial support for the Abbott concern. The personnel of the company will remain the same, with the exception that an executive officer will be appointed to succeed C. L. Lewis, who recently retired from the presidency to become affiliated with the General Engineering Co.

—

U. S. Truck Capital Now $1,000,000

CINCINNATI, OHIO, Aug. 21—The capital stock of the United States Motor Truck Co., this city, was increased from $300,000 to $1,000,000, at the recent stockholders' meeting, to take care of rapid growth of its business and to greatly increase its factory facilities.

This increase in stock was divided into both preferred and common, the preferred is cumulative 7 per cent, and participates in the earnings with the common up to 10 per cent.

The directors declared the regular annual dividend of 7 per cent on the preferred, and placed quite a large sum to the credit of surplus from the excess earnings.

—

Metcalf a Simplex Director and Vice-President

NEW BRUNSWICK, N. J., Aug. 21—Morris Metcalf was elected a director and vice-president of the Simplex Automobile Co., at a recent directors' meeting. He will be in charge of all the commercial departments, including sales, body, service and publicity.

—

Large Peerless War Truck Order

NEW YORK CITY, Aug. 18—One of the Allied governments has placed through Gaston, Williams & Wigmore an order for 2400 Peerless trucks, delivery to commence immediately. Delivery will be made at the rate of from eighty to 100 trucks a week until late in 1917.

—

Iowa Rubber Co. Formed

DAVENPORT, IOWA, Aug. 17—The Iowa Rubber Tire Co., capitalized at $1,000,000, was formed here recently, with a number of local men as incorporators. Chief among those interested are: J. W. Bettendorf, J. R. Lane and Judge J. W. Bollinger. A plant will be erected, either in Davenport or in Bettendorf, the suburb of this city, in the near future.

—

Browne Heads Anderson N. W. Division

DETROIT, MICH., Aug. 18—L. M. Browne, formerly of the eastern sales division of the Anderson Electric Car Co., this city, has been placed in charge of the northwest sales division, with headquarters in Minneapolis.

Timken Buys Out David Brown

Worm Gearing Concern Merged with Axle Company—Myers Leaves Organization

DETROIT, MICH., Aug. 21—The Timken-David Brown Co., this city, the majority of the stock in which was originally owned by the Timken-Detroit Axle Co., has been bought out entirely by the Timken-Detroit company, and the manufacturing operations will be consolidated under the management of the axle company. That portion of the Timken-David Brown stock which previously was not held by the Timken Axle Company was owned by David Brown & Sons, Huddersfield, England, and the new move divorces the two entirely. The Timken-David Brown Co. has always been regarded as a part of the Timken factories here, being under the same roof. It manufactures worm gearing for motor trucks and power transmissions, and the gear generating machinery was brought over originally from Huddersfield.

Coincident with the announcement of this merging of the Timken units comes information that Cornelius T. Myers, formerly chief engineer, and later manager in charge of engineering, manufacturing and sales of the Timken-David Brown Co. has severed his connection with the concern, disposing of his interests to the Timken-Detroit Axle Co. Mr. Myers, it is announced, will again take up consulting engineering in this city, making a specialty of motor truck, tractor and worm gearing applications to all kinds of power transmitting machinery. Myers has had an active engineering experience, having been mechanical engineer for the General Motors Co., and chief engineer of the General Motors Truck Co. He is a prominent member of the Society of Automobile Engineers.

Ford Agencies Increase Rapidly in Every City

Unrestricted Territory Plan Occasions Formation of Many Agencies—Ex-Salesmen of Ford Branches and Others Not Heretofore Connected with Ford Branches Have Become Retailers

NEW YORK CITY, Aug. 21—With the adoption of the new merchandising policy by the Ford Motor Co., hundreds of Ford salesmen have set up for themselves and in other instances have formed partnerships with their co-workers. In still other cases, they have readily obtained positions with the many new Ford agencies that are being established.

The unrestricted territory plan has occasioned the formation of many agencies even by those not heretofore connected with Ford branches and many garagemen, equipped to give service, have become Ford retailers. The change is most noticeable in those cities where there have been Ford branches. In towns where representation has been by a dealer only, new agencies as yet have not been established in any great number, and sometimes not at all.

One of the greatest changes will be in America's biggest city, New York. In Manhattan it is estimated there will be twenty-five or thirty and in Greater New York, which includes Brooklyn, Manhattan, the Bronx and Staten Island, fifty or more.

In Chicago, where there will be about thirty Ford dealers who will handle 10,000 Ford cars during the coming year; none of them will be allowed more than 500, and the minimum, according to the plan, will be ten.

In St. Louis nine new agencies are to be formed, making ten, including the Johnson Auto Co., the original Ford retailer. Several of these agencies have held openings, served lunch and entertained the public.

While additional appointments may be made, there are already in Milwaukee ten and in the suburbs two. In Wisconsin and upper Michigan, the business in the immediate future will be handled by 254 dealers of whom 238 are in Wisconsin and sixteen in upper Michigan. Many of these have been handling the Ford. The branch had thirty salesmen, most of whom have already made new connections.

In Louisville, Ky., four dealers have already been appointed, and in Lowell, Mass., the agency has been given up by Stephen L. Rochett of the Lowell Motor Mart, and has been taken over by Harry Pitts of the Pitts Auto Supply Co.

In Connecticut the number of dealers has been increased from twenty-two to thirty-eight. The Elmer Automobile Co. has controlled the territory and states that it plans to operate much as in the past. It has headquarters in Hartford with branches in Manchester, New Britain, Willimantic, Torrington and Winsted. John M. Butler, manager of the Elmer company said he expected to dispose of 28,000 cars during the next 12 months. Dealers, who heretofore have had more than one town, will concentrate on one town, which means an increase of 73 per cent in the number of dealers. It is stated that in Columbus, Ohio, the Ford branch, has, where possible, given preference to its former sales force. In fact, oustide of one dealer who formerly handled the county, every Ford agency in Columbus will be controlled by former Ford salesmen. There will be eight in all in the city and quite a few in the county, although it is said that most of the country dealers will be unchanged.

Ten of the fourteen Philadelphia salesmen have left the branch to open agencies.

Conditions similar to these exist throughout the United States, and while the unrestricted territory plan will vitally affect some dealers and distributers, there are instances in which the actual operation of the plan will be less revolutionary than its theory indicates. This belief seems to hold true especially with regard to country districts where agencies equipped to give service are not as numerous as in the cities.

Richmond, Va., will have at least four firms acting as Ford retailers. The factory representative will only sell the Ford automobiles, trucks and tractors at wholesale. It is stated that at least four agencies will be opened in Norfolk.

The Ford company in Pittsburgh has been besieged with applications for new agencies. The company has so far established nine agencies covering all parts of the city. It is expected that at least three or more agencies will be placed there.

Up to the present time about eight agencies will handle Ford cars in Washington, D. C. Applications for five other prospective agents are being considered. The fact that any dealer who wants to handle Ford cars will be limited in territory to the District of Columbia has come as a district surprise, as it was generally understood that under the new selling plan there would be no restrictions as to territory.

Five sales shops will be opened in Dallas, Tex. Three branches have been established in Baltimore, Md. Several of the Baltimore newspapers have been carrying blind advertisements asking prospective Ford buyers, who desire some special consideration to communicate. It is thought among the trade in that city that these cars will be sold on the payment of $100 deposit and $25 monthly. It is expected that there will be about twelve agencies in Baltimore. At present there is a little hesitancy on the part of prospective agents in the matter of forming companies on account of the guarantee to sell a car for every working day in the year. There is little doubt that the Ford company will dispose of about 5000 cars during the fiscal year to Aug. 1, 1917.

Twelve agencies are lined up in Minneapolis for Ford cars to replace the branch selling agency. Nine of these are closed and three are in abeyance. In some instances as high as three salesmen have gone with an agency. Contracts in the country remain as territory line-ups and are unchanged. In the city the minimum for cars is twelve.

Conditions will be somewhat similar in St. Paul. There will be eight to ten agencies, possibly more.

Parent Company Abandons Repair Business

DETROIT, MICH., Aug. 22—Supplementing the exclusive publication in last week's issue of the details of the new Ford selling plan, which is revolutionary in the automobile industry, complete information as to the workings of the new method of marketing Fords has now been secured.

The plan is really very simple in its workings, and requires only that the prospective dealer have financial responsibility and a garage at which he can take care of service for the car. The dealer can interpret the word service in any way he sees fit. Possibly Ford will continue to give service for some months yet at the various branches and assembly plants throughout the country, but when a man comes for service he will be told that that time is the last from the Ford company direct.

The number of cars that a dealer may secure for the year is based upon an estimate of his possibilities of selling them. There is a regular discount per car, and if the dealer meets the estimated number of cars he has arranged for per

month he will get a bonus on each car at the end of the fiscal year. If, for instance, a dealer contracts for twenty-five cars a month for the year and takes this number, his discount per car is increased by a bonus payment.

The number of agencies in any city or locality will be based upon the population and experience in that locality. In Detroit the maximum number is to be twenty-five agencies, and this will vary for other points. Already some eighteen dealers are either selling or getting ready to take contracts.

The contract limits the dealers to selling cars in Detroit, Highland Park and Grosse Point, which are really all a part of Greater Detroit. Thus, in any locality the dealers will have to confine themselves to certain selling fields as per their contracts. Dealers must do their own advertising.

American Vanadium Co. Sold for $7,000,000

PITTSBURGH, PA., Aug. 23—The American Vanadium Co., this city, which owns 92 per cent of the known deposits of vanadium and which sells very largely to the makers of high-speed tools and automobiles, has been taken over by eastern capitalists for $7,000,000. J. L. Replogle, Kuhn, Loeb & Co., Harrison Williams and others, are at the head of the syndicate.

Mr. Replogle, now vice-president and general manager of the company, will be made president after the conclusion of the sale. J. J. Flannery, head of the present company, will become chairman of the board.

A year ago American Vanadium stock was considered to be worth $152 a share. The last sale reported was made at about $600. The syndicate is offering $1,000 a share, of which $650 will be paid in cash and $350 in 6 per cent notes, or in the stock of the company. The new company, which will retain the name of the old, will have a capital of $13,500,000, made up of $5,000,000 of 7 per cent preferred stock, $6,000,000 of common, and $2,500,000 of 6 per cent short-term notes.

426,892,673 Barrels Petroleum in 1915

WASHINGTON, D. C., Aug. 19—Petroleum production in 1915 amounted to 426,892,673 barrels, exceeding the 1914 production by 28,194,307 barrels, or 7 per cent. Nineteen-fifteen was the most successful year of production in the history of the petroleum industry. The bulk of the increase in 1915 came from the United States and Mexico, though Russia, Argentina and Japan recorded significant gains.

The marketed production of crude petroleum in the United States in 1915 was 281,104,104 barrels of 42 gal. each.

20-Cent Gasoline Predicted

Fuel Continues Recession Throughout Country—Middle West Prices Lowest

NEW YORK CITY, Aug. 22—Gasoline continues its rapid drop in price. No logical reason is given for the sudden shift. All that is definitely known about it is that the investigation of the Federal Trade Commission had nothing to do with the reduction. Some authorities state that the recession is the outcome of the digging of new wells.

It is believed that gasoline prices will reach the low level of 20 cents a gal. in practically every section of the country within 2 weeks. Prices have been falling steadily throughout the West and Middle West during the past week. Figures collected from all parts of the country show that automobile owners of the Middle West, from Chicago to Denver, are paying the lowest price at present for gasoline. Chicago and Des Moines quoted the lowest price, 17½ cents, and the average is 18 to 19 cents. These prices average 2 cents below the rest of the country. The Standard Oil Co. has reduced prices in St. Louis to 17.9 to 16.9 at filling stations. The independents in that city also commenced quoting the same price. The first drop in gasoline prices in the Rocky Mountain section occurred on Aug. 15, when a cut of 1 cent was made. Oil companies there are wholesaling to garage and filling stations at 22 cents a gal. Columbus prices have been cut a cent to 22 by the Standard Oil Co.

A reduction of 1 cent per gal. for the lower tests of gasoline was made effective in Milwaukee and throughout Wisconsin and Upper Michigan this week. The Standard Oil Co. and the independents authorized the drops at the same time. Present quotation at filling stations or delivered in Milwaukee, is 17.6 cents per gal. on the Red Crown grade. The independents' lowest test, marked 59 deg., is now 17.6 cents, tank-wagon basis, or 18.6 cents, filling stations. Higher tests, or grades running from 65 to 74 deg., are not affected by the reduction. Practically all retailing of gasoline in Milwaukee is now done directly by the Standard and independent companies through filling stations. Garages which sell gasoline for the most part do so on commission for the big wholesalers and thus are designated as filling stations for these companies. Garages connected with agencies for cars do not want gasoline trade because it is wholly unprofitable.

The Texas Co. to-day announces reductions of 1 cent a gal. tank-wagon basis, to conform with cuts by competitors in the territories named, as follows: Illinois, to 17½ cents; Minnesota to 18½ cents; Missouri to 16.9 cents minimum, 17½ maximum; Florida to 22 cents minimum, 22½ cents maximum; Georgia, 22 cents minimum, 25 cents maximum; Louisiana, 18½ cents minimum, 20½ cents maximum; Mississippi, 20½ cents minimum and 22½ cents maximum; Alabama, 22½ cents minimum, 26 cents maximum; and Ohio, 21 cents.

The Eastern section of the country has also been favorably affected the shift in prices, though the average price being paid is somewhat higher than in the West. Pittsburgh prices, retail, have been cut 2 cents a gal. within the last 4 days, quotations prevailing at from 22 to 23 cents. Detroit prices, tank wagon basis, have been reduced 1 cent to 18 cents. Buffalo owners are paying 23 cents and in Albany prices are ranging around 25 cents per gal. New Yorkers are paying 23 cents a gal. in 1000 gal. lots. Gasoline in New York City may now be had at the Socony stations at 23 cents a gal., though, representing a drop of 3 cents since the beginning of last week. Louisville prices have received a further cut of 1 cent to 20 cents wholesale.

Gasoline Report Expected Soon

WASHINGTON, D. C., Aug. 19—The Federal Trade Commission met again to-day to consider the gasoline phase of its oil investigation that has been in progress for several months. It announced that the report on gasoline would be issued shortly, but those in close touch with the commission say the report will not be submitted before the adjournment of Congress. That the commission was co-operating closely with the Department of Justice also was learned When the investigation was first inaugurated, such co-operation was planned; any specific complaints in regard to gasoline prices were to be turned over to the trade commission and anything of interest to the Department of Justice was to be noted.

G. C. Todd, assistant attorney general in charge of anti-trust prosecutions, met with the commission to-day and listened to some of the information it has collected to report to Congress on the causes for the rise in the price of gasoline. The Department of Justice has kept an eye on the companies into which the old Standard Oil Co. was dissolved under the supreme court decree several years ago, but never has discovered evidence to show that decree has been violated. Mr. Todd declined to discuss the value of the evidence collected by the trade commission, but it was understood that so far the Department of Justice had not determined whether there was new information in government hands to warrant proceedings.

ACCESSORIES In South America

No. I

With 30,000 U. S. A. Cars in Argentina There Is No Doubt As to the Great Value of Field

By David Beecroft

"IT is hard to do business with the accessory manufacturers in the United States of America. I carry a stock of accessories here worth $50,000 United States gold. I sell the majority of my accessories to be paid for in 60 and 90 days. I cannot sell for cash. If I try to the buyer goes to three of four other places in the city."

Antonia Prado, owning and conducting one of the largest supply houses in San Paulo, Brazil, so summed up his attitude with regard to our accessory makers. Señor Prado only said what several other supply houses in different parts of Brazil and Argentina told me at different times. There was a startling unanimity of criticisms from many different cities within the course of a few weeks. They all told the same story:

"It is hard to do business with United States of America accessory firms."

There is literally no reason for such a verdict being lodged against us. These South American accessory dealers and supply house people want our accessories. They want our accessories because in many instances they cannot get any from France, England, Germany, Belgium, Italy and the other European countries they have been in the habit of buying from.

Again: They want our accessories because to-day there is a lot of U. S. A. cars through these South American countries, and it is imperative that owners of these cars secure necessary accessories.

Speedometer Shortage

Take a few examples: The majority of Ford cars sold in Argentina, Uruguay, Chile and Brazil are sold without speedometers. A car owner on the Argentine pampas is just as anxious to know how far he goes in a day as a motorist in New Jersey or Connecticut. You have more need for an odometer in Argentina and Brazil than you have in New York State or Pennsylvania. In Argentina, through the country or camp, you travel uncharted roads and have every need for the speedometer and the odometer. The same is true in other countries such as Chile, Uruguay and Brazil.

Try to buy U. S. A. speedometers and you cannot buy them in many places; in fact, it is the exception if you can buy them. We tried in four different cities outside of Buenos Aires in Argentina and could not. These supply houses generally buy from the three or four large houses in Buenos Aires, but complain that they are not able to get supplies in quantities. They may be able to get three or four or perhaps a dozen speedometers, but that does not in any sense meet the requirements. Two of the supply houses in Buenos Aires showed quite a don't-care attitude toward our cars and accessories. One house has strong German sympathies and the other leans strongly to the French. The third and perhaps the largest is very favorable to U. S. A. goods and is eager for information on the accessory field in U. S. A.

¶ *This is the first of three articles outlining what accessories there is a good market for and what business principles should be followed in the business.*

Delays on Shipments

This speedometer example can be applied to other lines of our accessories. Here is example No. 2:

While in Rosario, a city of 400,000, and 6 hr. by train from Buenos Aires, the following information was given before I had an opportunity of getting properly seated in the office:

"On Jan. 16 I placed an order for U. S. A. accessories through a New York shipping house. Under date of March 22, I got an acknowledgment stating the goods were being shipped by same steamer and would arrive by the end of April. To-day it is June 5 and I have not heard of the goods. I am out of stock and cannot get any in Buenos Aires. I am sending a second order to this same firm. I do not know when my first order will arrive, but I must have goods and am placing a second order and I may have to place a third order before I get the first order of goods. The U. S. A. cars are selling around here and I need these accessories."

This is a story you will get in seven or eight different cities in Argentina. It is a story I got in Uruguay, and it is similar to stories I got at two cities in Brazil.

Before trying to answer why it is hard for the supply house men and accessory men in Argentina and Brazil to do business with us, let us see if the possible field in Argentina is worth while. We take Argentina first because it is the greatest field for U. S. A. cars, trucks, tractors and accessories in South America.

There are many accessories which we manufacture that will prove popular there, and are proving good sellers to-day. In perhaps twenty supply houses in ten or twelve different cities in three different countries we went over a good percentage of the accessory stock on hand to see what U. S. A. goods were being carried and also to ascertain what lines were proving good sellers. We found a fair repre-

sentation of U. S. A. goods and saw many articles that are big sellers. We found many lines of French and German goods and also many English, Italian and Belgian lines.

Thirty Thousand Cars in Argentina

From a careful canvas of all sources there are approximately 30,000 automobiles in Argentina. Here are some figures on automobile imports that very nearly give this total:

Argentine Total Automobile Imp.	U. S. A. Automobiles Imported
Prev. to 1905..3,517 cars imported	1905 to 1909..... 333 cars
1905 to 1909... 244 cars imported	1910..... 217 cars
1910...1,581 cars imported	1911..... 489 cars
1911...2,461 cars imported	1912..... 708 cars
1912..4,281 cars imported	1913.....1,296 cars
1913..5,515 cars imported	1914.....2,100 cars
1914..3,004 cars imported	1915.....1,400 cars
1915..1,838 cars imported	1916.....4,444 cars
1916..4,444 cars imported	

These 30,000 cars, of which 8000 are U. S. A. cars, require many lines of accessories that call for frequent renewal. They call for certain supplies not falling in the line of accessories that can only be supplied by U. S. A. to-day. These 30,000 cars call for certain garage supplies that can really only be obtained from this country at present. The accessory market for these 30,000 cars exists, thanks to no special efforts we have taken, but due to the misfortunes of others. These 30,000 cars are literally asking for our accessories and yet we are not even making it easy for the supply house people there to do business with us. This is their outspoken verdict.

What does 30,000 cars mean as a possible accessory field?

Hand Horns in Demand

Some of the best U. S. A. sellers are hand horns, soaps, body polishes, spark plugs, speedometers, batteries, vulcanizers and dry cells.

Hand horns are very good sellers, but we rarely saw more than one or two different makes. Each of the 30,000 cars in Argentina is a prospective market for a hand horn. The field is large enough to warrant our large horn makers starting after. They should at least get their feet firmly on the ground. Very often when you asked where the dealer bought the goods he remarked, "From a New York exporting house." As to why he did this the answer came that so many of the accessory houses were hard to do business with. They had not Spanish stenographers, they did not know how to properly pack goods for ocean shipment and there were other excuses. These dealers were willing to pay an exporting house 2.5 per cent more for the goods solely because it was easier to do business in that way than with the manufacturer.

If our accessory manufacturers are asking themselves if it is worth while going after export business or not, let them not forget that during the fiscal year ending June 30, 1916, practically 8.5 per cent of our entire automobiles manufactured were exported. Where these exported cars go our accessories should follow. We are to-day becoming an exporting nation of such proportions that our makers must seriously consider this export question. We have a big export business to Europe, Canada, Australia, South America, West Indies, Africa and Asia. We can scarcely afford to close our eyes to the magnetism that our cars exert in these countries, and it is poor business if our accessory makers do not at least try to follow in the wake of our car builders in the export field.

Requests for Polishes

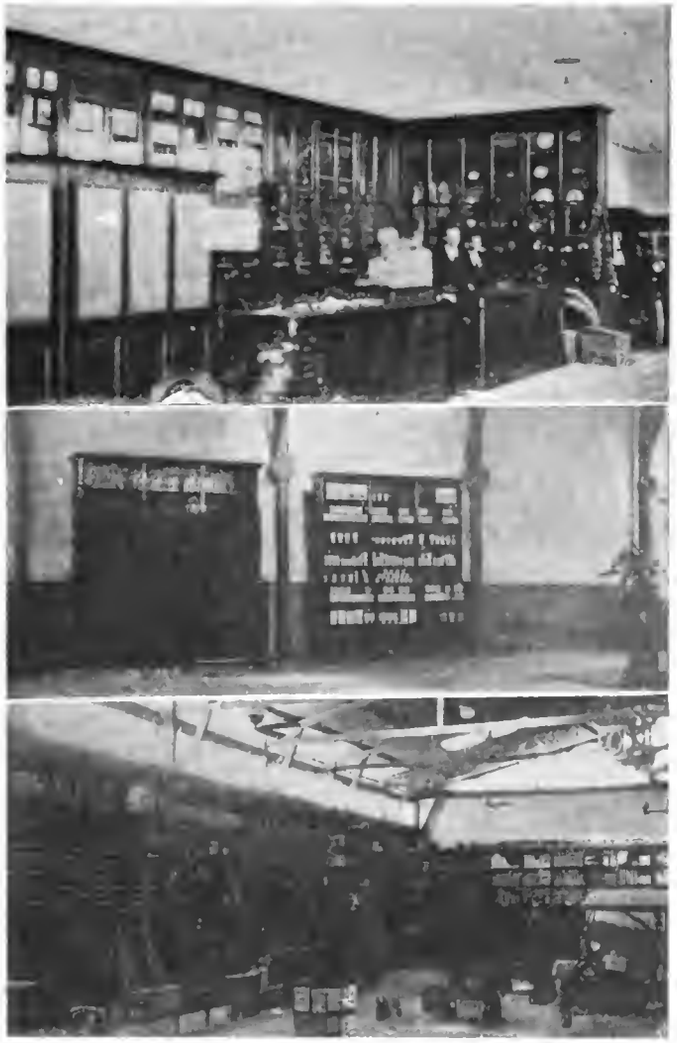
Metal and body polishes are good sellers in South America, where many of the chauffeurs are required to wash and polish their own cars. It is very common to do this, particularly where the cars are kept in individual stalls under lock and key. The driver is entirely responsible, and if a single scratch appears he is looked to. This means a very wide market for polishes. One or two supply house men wanted such in litre cans to retail at 75 cents, United States gold.

There is a brisk market for soaps and hand cleaners. Where each chauffeur becomes a body polisher it is essential that he have plenty of soap. More soap is needed per car per month than with our system of washing where four or five men in one garage wash 100 cars. We need soap for four men, whereas South America needs it for 100.

Spark Plugs Very Strong

Spark plugs are fine sellers. In nearly every supply house you see three or four makes of U. S. A. plugs, three or four French makes, one or two German, a couple of English and perhaps one Italian. You meet with Champion, A-c, Bethlehem, Mosler, Grossman, Splitdorf and some others. One criticism applies to nearly all of our plugs sent to

Goodyear tire establishment in Buenos Aires, Argentine Republic. This is typical of the high-grade accessory quarters and also illustrates the Spanish tendency of the South American architecture. The wide street should be noted. This is also typical of Buenos Aires



Top—Cadillac agency supply department in Cordoba, Argentine. Center—Valentine varnish display in Cordoba accessory store. Lower—U. S. A. accessories on shelves in a Cordoba shop

Argentina and Brazil, namely, that prices are marked on the cases. The same pasteboard boxes seen in Chicago or Kansas City supply houses are seen in Buenos Aires, Rio, Sao Paulo. This is bad. If a spark plug sells for $1 in New York it is a certainty that it cannot sell for $1 in Buenos Aires. The sign $ is the same in Buenos Aires that it is in New York, but the $ in Buenos Aires stands for only 44 cents of United States gold. In Buenos Aires that plug may sell for $4. You readily see the difficulty of a dealer trying to convince the buyer to pay $4 when the sign in plain figures on the pasteboard box is $1.

Our spark plug people who do business direct with Argentina should leave all prices off their goods. You should get special boxes with all reading in Spanish and leave the price off. Germany learned to do this some years ago and very often when you see German plugs they are in neat pasteboard boxes with the reading in Spanish. The Argentines like such. It makes sales easier. For Brazilian trade have the prices left off and print the reading in Portuguese.

The South American dealer has his troubles getting spark plugs into the country. Here is what a large supply dealer in Cordoba, Argentina, told me, and substantiated it by documents. Cordoba is a city of 140,000 located in the central part of Argentina and a night's ride by train from Buenos Aires.

The dealer has constant troubles with the custom authorities: He buys them in cases of a dozen, and out of each case there is stolen in the customs two plugs. He pays $5 United States gold in New York for the dozen and has to get his profit out of the ten reaching him. He has to add $3.52 for freights, customs, insurance, etc., so that the plugs cost him practically 85 cents United States gold each. He sells them for $1.32 United States gold each in order to break even.

This custom house trouble is not new in many of the South American countries. Very often several of such small articles are missing and the custom officials seem so strongly entrenched in their positions that nothing remains but to accept the inevitable. While in Rio de Janeiro a U. S. A. citizen had a 3-lb. box of chocolates forwarded from a friend in New York. It took nearly a week to get the box through the customs. Three different custom authorities were engaged in the job, and when the chocolates finally arrived the entire top layer was missing. There was no use complaining. The trouble is not local to automobile accessory concerns, but unfortunately is a serious one in South America, and one that must be settled sooner or later.

Need Tire Vulcanizers

Reverting to the accessory field, there are many other U. S. A. lines that you already see in South America, but which have been purchased through New York exporting houses and the makers may yet be ignorant of the fact that their goods are on sale in South America. You ask every supply manager where he buys his goods and he generally replies that it is through an exporting house. It astounds you to think that some of our largest accessory houses are not selling direct to these large South American dealers. Selling direct would give their goods better representation and the maker would be much closer to the market.

Our tire vulcanizers are not well represented. Every one of the 30,000 cars in Argentina has tire troubles, and they are just as careful of their tires as we are, in fact, more so. There is a good market for small vulcanizers, such as chauffeurs can use. There is also a good market for shop vulcanizers, for nearly every garage is well prepared to look after tire repairs. We saw in Cordoba one of the most up-to-date vulcanizing departments that could be found, the goods all coming from a U. S. A. house.

Weed chains are strong sellers in every part of South America where U. S. A. cars are sold. Many Ford dealers sell the chains as a part of the car equipment. The same is true with several of the other makes. Our cars are generally going into the camp or country where roads are not good in many places, but where the cars must go nevertheless. Chains are an essential. Oversize tires are generally sold. Every Ford dealer is stocked with Weed chains, but in many places their stocks were running low in June.

Ford slip covers are popular and good sellers. All South American countries are favorably disposed toward slip covers for seats. They are universal in the cities and the demand for them in the country gives good promise.

Gear Blanks Needed

Forge companies can do a fairly good trade in gear blanks of all sizes. Many of the large dealers in Argentina and Brazil are well equipped with gear cutting machines. You will see some of the finest German, Swiss and French machines, but too few of ours. These gear cutters will handle any size of spur or bevel used in an automobile. The dealers found it good business to fit up with such machinery.

There is a good market for steel stock in all bar sizes. The large accessory supply houses handle it.

In every supply house you will see spring clips of all sizes and similar forgings for cars. It is impossible to mention what accessories are not needed in South America. The same accessories that we use they will have to use. There did seem to be a dearth of shock absorbers, particularly the cheaper types that are in such general use on Ford cars in

U. S. A. With bad roads the rule in Brazil and Argentina it is certain that the shock absorber business will have a good field.

Paint and varnish concerns have a relatively strong field. There is a great deal of car repainting in the cities, but not so much in the camp. One supply house dealer had a large stock of Valentine goods, and had them well displayed in a special show case.

Brake Lining Needed

There is a good market for various makes of U. S. A. asbestos-copper brake facing and facings of other compositions. You meet with one or two makes, but frequently find that a supply house is short of many sizes. Keeping an adequate stock is a problem. The supply house man orders only fair-sized lots because he pays cash or sometimes cash against document in New York. In order not to keep his money tied up too long his purchases are not so large as they should be. Selling on 90 days' time will solve that difficulty and result in larger sales. The U. S. A. maker can charge, perhaps, 8 per cent extra for the time, and in addition will find his sales increasing.

We found very general requests for priming cups and grease cups. Solely because you have to cross the equator to get to Argentina is no reason to imagine that it is always hot there. Argentina has its seasons just as we have. It has its winters, and they are cold. We were there in May and June during their fall, for their seasons are directly opposite to ours, and although we wore our New York winter overcoat we were colder than in New York in February. It gets very cold in Argentina, and you feel it more so because the buildings are not heated. Garages are not heated, and naturally a car gets very cold, making priming cups an essential. There was a shortage of them in one or two places.

Grease cups of all sizes are needed. For European cars the metric thread is best, but for U. S. A. cars our standard threads will do. It would be beneficial to us if we used the metric threads on all of such parts, as it would simplify our export trade.

Big Bearing Field

Our bearing concerns are not so well represented as they should be. One of the surprises that meet you when looking through large accessory supply houses and in many garages is the large stock of bearings carried. I have seen two shelves over 12 ft. long each piled nearly 1 ft. high from end to end and for nearly a foot in width with various sizes of French, English, German, Swiss, Italian and Belgian ball bearings. You soon see the reason. Argentina is 3 weeks from Europe, and it is necessary to keep very large stocks. We found New Departures in one or two places; we found Hyatts stocked in a few places, but looked for several other makes that should have been represented, because of U. S. A. cars being sold, but could not find them. Our ball and roller bearing makers should get into the South American field. They will have to supply bearings for the U. S. A. cars, but there is no reason why our ball-bearing makers should not be supplying for a percentage of the European cars. The field is there. We must get after it.

Demand for Lamps

A brisk demand was noted for hand electric repair lamps. So many of the European cars use acetylene lighting that the electric repair lamps are good sellers. There is in this connection a good possible market for the individual electric searchlight which we fit to the frame of the windshield and operate by hand. The Argentines are fond of attachments, and their poor roads would make such a lamp very attractive. Lamps are heavily stocked in all supply houses.

Several requests were made for top-covering materials which are cut and ready to be used in recovering such standard models as the Overland, Ford, Buick and others. Tops are not given good attention in Argentina; in fact, all of our cars going into the camp get rough usage. Sometimes they are never under cover for months. To make a speedy top-recovering job these tops, cut ready to be applied, are much in demand. The life of a top in Argentina is considerably less than the life of one in our own West.

Ford Dealers Good Sellers

Nearly all Ford dealers carry a large stock of accessories, including two or three tire lines. The Ford dealer in Cordoba, Argentina, has the whole side of his shop occupied with one large showcase with glass front. It is filled with Ford spare parts and all of the accessories he can get. He was short of Ford accessories in June. He can sell 200 Fords per year if he can get them, and as all cars arrive without speedometers he was particularly anxious to get such lines. He does not want speedometers that read in miles per hour, but they must read in kilometers per hour.

(To be continued next week)

Studebaker agency along a South American automobile row. In a great many instances in South America the dealer in cars will also carry a wide range of supplies both for automobiles and other purposes. The illustration herewith shows an agency which is devoted to the sale of Studebaker cars and which is typical of the case where an American maker has secured a firm foot-hold

British Idea of Inexpensive Car Vastly Different from American

Suggested Chassis for Quantity Production in England After War Has Many Novel Points—Elimination of Moving Parts Studied with Exceptional Thoroughness

OUR British contemporary, *The Automobile Engineer*, has in its July issue a suggested specification for a car which the author considers could be produced in England after the war to sell for $800. In the light of American manufacturing experience there are many points which are highly debatable: for instance, it is stated that if a four passenger car could be sold for $800, the two-passenger roadster ought not to cost more than $750, which suggests a misconception as to the relative cost of bodywork made in a modern fashion. However, the article is not concerned so much with the details of cost as to show the general way in which cost can be cut and to "convey some impression of the *kind* of chassis that is required, as it is feared that the average British manufacturer starting on the production of a quantity car will inevitably end up by producing something of a quality in excess of what is required for the market and the purpose for which the chassis is intended."

As such it certainly creates thought. The authorship is not stated, but it is easy to see that American practice has been studied carefully, has even been taken to greater lengths than any engineer in America has yet dared to carry it. Another striking point, wherein the chassis differs from American practice, is its lightness of detail. The enormous overhang on the front axle and the almost flimsy construction of the rear axle would be suitable to the smooth highways of the old world, no doubt, but hardly in a rougher country.

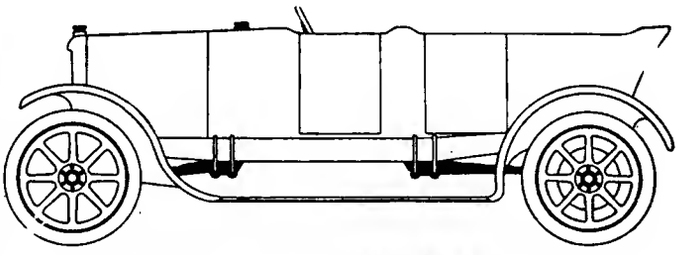
Doubt About Spring Suspension

The author himself is obviously doubtful about the spring suspension. With the points of attachment so close together the "spring base" of the car becomes so small that rolling and plunging would seem almost certain faults. It is rather surprising that this suspension should even be considered as practicable in a country where high speed is the rule. There would seem to be possible advantages in shortening the wheelbase somewhat and reversing the rear springs so that they are attached to the rear end of the frame and point forward to the axle, as was done with marked success on the baby Peugeot, which has the same type of shackleless springs. Even a cross spring at the rear would seem better than the type suggested.

However, it is not fair to criticise without quoting the author's own description of his ideas which follows:

"The main points that have been borne in mind in the chassis lay-out given are economy in detail manufacturing costs, economy from the point of view of erecting shop costs, and economy of attention when in use. The last-named objective is a most important one, and to carry out this scheme all possible 'attention-requiring' points must be eliminated. No greaser or oilcan hole must occur in the chassis. On this account fixed cantilever springs fore and aft are adopted. These are rigidly clipped to both axles and frame, so that the use of shackles, spring bolts, etc., is avoided, and the suspension thus embodies no moving parts.

"For steering connections the O.S. bearings or bearings of this type are suggested. The O.S. bearings are American productions, and are of a nature that is different from ordinary British practice. The wearing or bearing surfaces consist of compressed graphite impregnated material that needs no attention in use. In this way steering or other likely parts are made self-lubricated, or lubricated statically instead of dynamically.



Exterior appearance of British idea of an $800 quantity production car

"The engine, clutch, gear, and steering formed an integrally oiled unit in the original lay-out, but from the viewpoint of production economy it was deemed advisable to separate the steering gear, the advantage of self-lubrication of this unit scarcely warranting the extra complexity involved in the casting. This is a debatable point, and it may still be found advisable to combine the parts in the manner suggested. Both foot and hand brake actuation is by cable—an arrangement that gives at once compensation and freedom from pin joint and other 'attention-needing' spots.

"By reference to the general arrangement of the chassis it will be seen that, for side members, two straight channel pressings are proposed. They are of good deep section at the center, tapering away at either end, and are set up at the rear to allow for back axle movement. Being without curves or formed dumb-irons, economy is effected in die costs, and also in production prices, as the shaping of the dumb-iron bend on a side member adds considerably to its cost; moreover, even when the channel has been bent and completed, the actual dumb-iron brackets, either castings or stampings, must be provided.

"Four cross members are used, the rear cross member being strongly reinforced by angle plates to insure stability endways. At the front of the chassis the two engine arms, by being made of particular strength, might be employed to serve as a cross member, so that the extreme front cross channel might conceivably be eliminated altogether. This cross member, instead of carrying the starting handle, has a starting handle bracket that is blanked off by a cap fitted in front, as is usual where a starting motor is installed. In the event of the front cross channel being eliminated, an extension of the timing gear cover casting could be arranged to form the starting handle bracket. If this scheme were adopted, it would be as well to carry the engine feet as far forward as possible on the crankcase. The steering box is attached by the engine foot bolt, an arm on the box clamping between the engine arm and the frame block. This enables the steering column angle to be readily set for two or four-seaters. A steering column bracket on the dash insures rigidity.

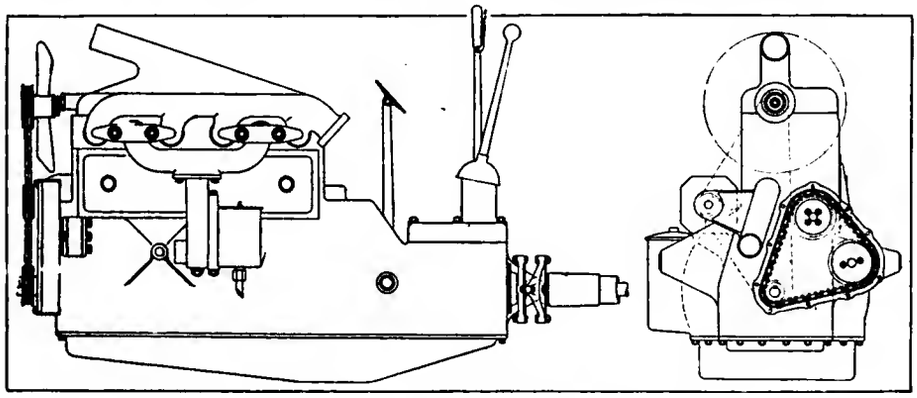
"The springs—fixed cantilevers front and rear—are bolted direct to the underneath of the channel section by clips circling completely round the side members and springs. The extremities of the springs are, as previously mentioned, clipped rigidly to both axles, half the spring end being turned down and a corresponding turn up on the spring seating being used to form a natural register in both directions to avoid any necessity for doweling or machining of spring seatings in order to obtain location.

"This system of suspension offers many advantages from the viewpoint that has been adopted in this particular lay-out, as not only does it give extremely low cost in manufacture and erection, but it is also in line with the minimum of attention and trouble ideal upon which this, and for that matter most future cars, will be laid out. There being no spring pins, spring bolts, shackles, greasers, etc., the suspension should last indefinitely, provided the springs themselves are wrapped up. While considering this system, it is as well not to overlook the fact that it possesses one or two rather obvious disadvantages. If the system is adopted without tie or radius rods, as shown in the drawings, it will evidently be necessary to have as light an engine as possible. The lateral stability of such a system is poor, and too much mass directly over springs of the type shown is inadvisable, and would inevitably make the front of the car roll. A further point is that, having one coupling point only to the frame, breakage of a spring might prove more disastrous than in the ordinary semi-elliptic lay-out. Much depends upon quality of material and design, and with care such an arrangement should be safe enough; it has been employed on one or two chassis of light build, and is apparently satisfactory.

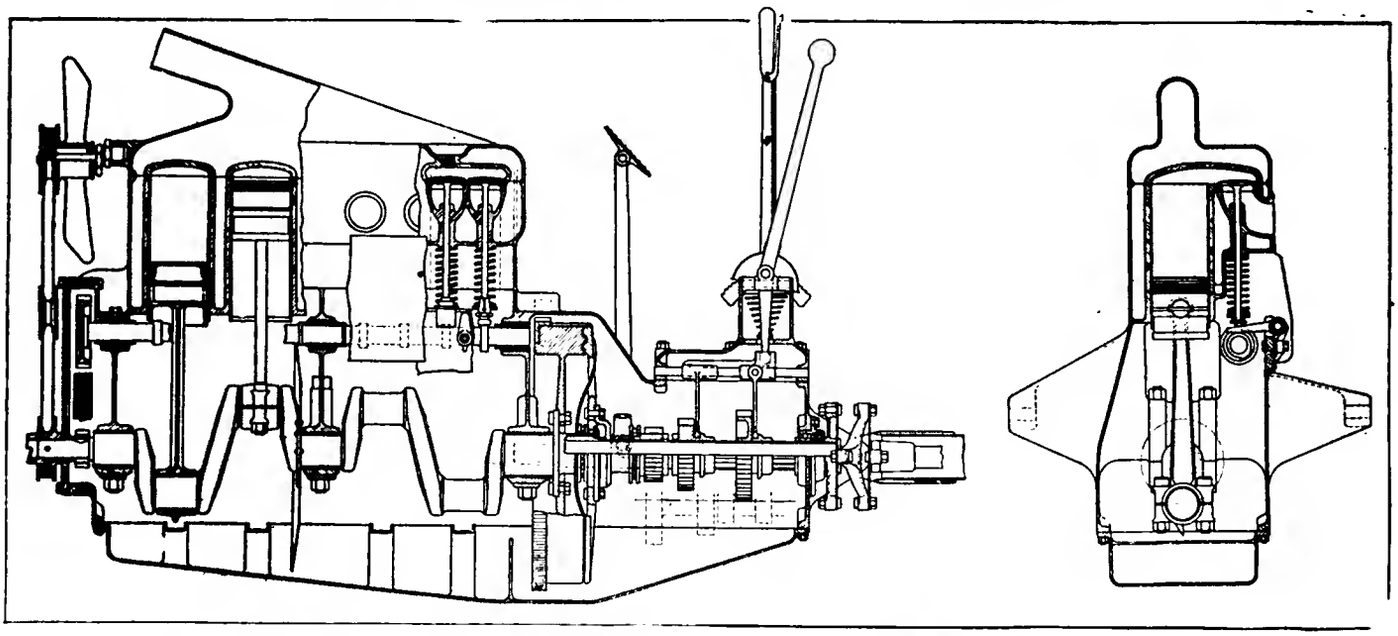
"The lay-out in these pages is for a 3⅛ in. by 4¾ in. engine, but evidently the general scheme is applicable to an engine of anything about this size; 3½ in. by 4¾ in. would probably be better, but it seems, however, that 3⅛ by 4¾ in. certainly under present and possible future persecution will be all that any ordinary human being will be able to pay for; moreover, fuel prices and probable shortage even after the war will make small capacity engines essential. The engine body and cylinders are a one piece aluminum casting with the gear box also. Separate cylinder linings and valve seats will, of course, be necessary with the material proposed, but aluminum gives so many advantages in other ways that it will probably not be found an unpractical arrangement, assuming normal material prices. This proposal, particularly with the large size casting outlined, is admittedly an optimistic one; whether or not we have a firm of founders in this country capable of tackling such a job is an open question. The proposal, however, is not an impossible one, and with a large output would be worth while. In any case, slight modification of the casting—such as the provision of a vertical joint somewhere in the flywheel or clutch region—would make the casting problem much simpler. This arrangement, nevertheless, would add to machining and erecting costs, and on that score would be best avoided.

"Aluminum pistons would be used, the gudgeon pin being probably fixed in the connecting-rod and turning in the piston.

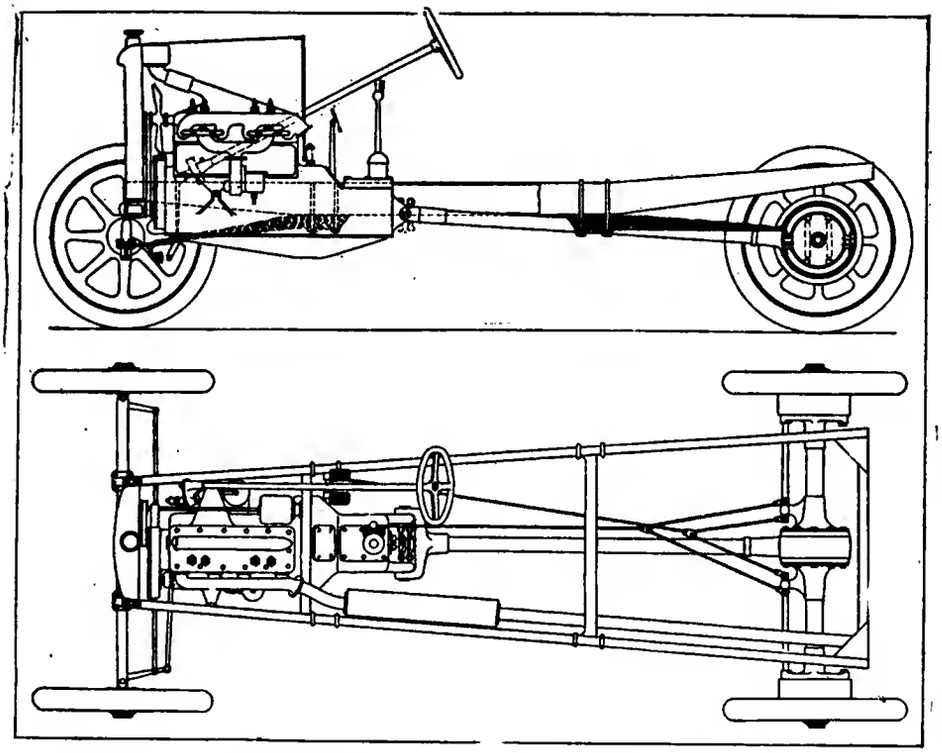
A detachable head with integral water outlet that can also be of aluminum is suggested. A chain-driven camshaft is proposed, the chain extending in triangular form, as seen in the front end view, to drive also the distributer. For chain adjustment the distributer, and its driving wheel, slide in the timing gear case, the joint face on the outside of the casing being covered by the flange on the distributer bearing. Slots in this flanged bearing permit of the necessary sideway movement.



Exterior of unit power plant to be used in a British low priced large production automobile



Section through motor suggested as suitable for a low priced car to be manufactured in British shops



Elevational and plan views of a low priced chassis, suggested for British production

"The water inlet pipe to the cylinders from the bottom of the radiator is incorporated in the main casting, and will be seen alongside the timing gear in the end view of the engine. On the side of the inlet water pipe the dynamotor driving spindle bracket is shown—also cast on—an arrangement that would probably make more for complexity than simplicity. The better plan would probably be to bolt this on as a separate part. The water pipe butts against the pipe on the bottom of the radiator, a rubber ring being employed, making a joint against the faces or ends of the pipes in place of the usual hose pipe type of connection.

"Obviously the main casting is sufficiently complex as it stands, and for this reason the inlet and exhaust branches are separate, being attached to the cylinder by dogs and clamping set-screws.

"With an aluminum cylinder block there is not much option as to the matter of making the exhaust branch separate or otherwise, as aluminum is scarcely suited to be the first receiver of hot and unexpanded exhaust gases.

"With a view to economy, it is suggested that the usual valve pressers and guides be done away with and a rocking lever system of presser be substituted, an adjustable end to the valve being used in place of the usual method of valve adjustment. This arrangement lends itself to economical construction, as all the rocking levers can be threaded on a tube with tube distance pieces, the whole assembly being then clamped against the front of the casting.

"With the general lay-out of gear and clutch shown it is evidently of vital importance to reduce to a minimum the length of the mainshaft. It is quite possible that the length of the unsupported mainshaft in the arrangement shown will produce a noisy box. On the other hand, with a view to economy, it is important to keep the number of bearings to a minimum, and on these accounts a compact narrow clutch is imperative; further, all increase in clutch length and movement means increase of shaft length, so that the reasons for the arrangement shown are fairly evident. It is difficult to arrange an economical design of the ordinary single plate clutch, the actuation for clutches of this type being usually fairly costly.

"The splitting up of the cone surfaces into steps will increase the speed of engagement in direct proportion to the number of steps, a clutch with a large number of steps giving practically instantaneous clutching if arranged with the cone usual angle. On this account the angle of the clutch cone becomes much greater than usual, the angle in the clutch illustrated to transmit the necessary power coming out at about 60 deg. to the horizontal with the leverages adopted, and using a spring requiring reasonably light pressure at the pedal pad for disengagement.

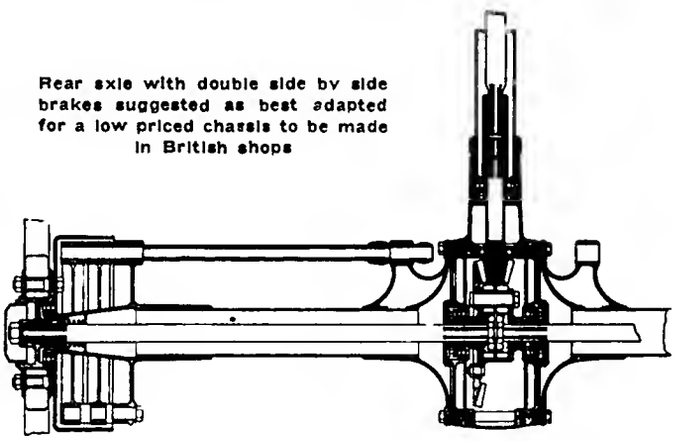
"Three speeds and reverse are suggested for the gearbox, with all sliding wheels arranged on the mainshaft. The selector, or striking lever, gate and selector mechanism, are all in a single casting that forms the gearbox cover.

"With regard to oiling details, considerable economy over the usual systems must be effected, and it is suggested that for the purpose of oil delivery a large pressing or spinning should be attached to the crankshaft center to form an oil thrower. Oil is lifted from the central portion of the sump, and thrown up into the delivery well or collector, seen on the off side of the engine body. This pot or collector forms also the oil filler, and has been arranged so that oil delivered into it is filtered, and feeds the four troughs under the big ends. Oil will inevitably be delivered by the thrower faster than it can run to the troughs, and a higher level overflow from the collector delivers to the gearbox, whence the oil flows back to the sump over the central dividing web into the crankcase, maintaining a constant level in the gearbox, and circulation to all parts of the system without much expense, complexity, or the use of an oil pump. The usual oil wells would be provided for the camshaft and crankshaft bearings to hold the splashed oil.

"With regard to arrangements at the rear, it is suggested that a torque tube be employed sliding in a T-piece of broad base that fulcrums on pins through brackets on the gearbox.

"The rear axle lay-out, as shown, is necessarily very tentative; that is to say, in certain particulars it depends so much on what is obtainable in the way of large-sized pressings. On this account the outer casing construction is extremely difficult to settle. That shown in the drawing is a large diameter tube with castings at each end, the one being the differential box end or cover and the other the axle tube end and spring seating. Both brakes are on the rear wheels,

Rear axle with double side by side brakes suggested as best adapted for a low priced chassis to be made in British shops



Measuring gasoline and on the road on the King test

King Economy Test Over the Road

From Pittsburgh to Milwaukee Under Touring Conditions Average Over 14.6 m.p.g.

CHICAGO, ILL., Aug. 19—A fuel economy test under actual touring conditions over the roads from Pittsburgh to Milwaukee has just been concluded by a King eight-cylinder, seven-passenger, stock touring car. The average was 14.658 miles per gallon of gasoline and 962.4 miles per gallon of oil. The run was in charge of F. E. Edwards of the Technical Committee of the American Automobile Association accompanied by A. A. A. observers.

In his application for a sanction Artemus Ward, Jr., president of the King company specified a car owner fuel test to be run under touring conditions. The association was asked to conduct the test in such a way as to determine the mileage that an owner would secure in touring and not a maximum economy record. No change in the equipment of the car was made.

The car left Pittsburgh at 8 a. m., Aug. 15 and travelled to Milwaukee by way of Youngstown, Cleveland, Toledo, South Bend and Chicago, covering all sorts of roads during the 616.4 miles. An average speed of 19.44 m.p.h. was made including stops and 22.67 m.p.h. excluding stops. Gasoline was measured to the fraction of an ounce. The car was the regular eight-cylinder King, 3-in. bore, 5-in. stroke, Ball & Ball carbureter, nozzle size 70, Atwater Kent ignition, Ward-Leonard electric units, Carter gravity feed, Champion plugs and Firestone tires. Mobiloil B was used and a Boyce Moto-Meter and a spot light were fitted. The car weighed 4250 lb. with full passenger load.

Summary of Stock King On-the-Road Fuel Test

From Pittsburgh, Pa., to Milwaukee, Wis.
Miles traveled, 616.4.
Gasoline consumed, 42 gal. 7 oz.
Oil consumed, 2.5 quarts.
Water consumed, 1 gal.
Miles per gallon of fuel, 14.658.
Miles per gallon of oil, 962.4.
Miles per gallon of water, 616.4.
Tires—finished on Pittsburgh air.
Miles per hour, including all stops, 19.44.
Miles per hour, excluding all stops, 22.67.
Number of stops at controls, 6; duration, 2 hr. 50 min.

---

a necessity from the point of view of economy in detail and erection, and wire cable is employed for the actuation of both brakes, as this gives a ready and inexpensive compensation, and eliminates the brake cross-shafts, brackets, etc., etc., with advantages both from the viewpoints of production economy and minimum of lubrication attention in use. Arrangement could be made to conduct a portion of the rear axle lubricant to the brake actuation shafts and fulcrum pins, so that no outside attention was required.

"It was originally intended to include among the published drawings an axle scheme without a differential. In the low-priced chassis the differential does not really justify itself, it having been repeatedly proved that tire wear on an axle without a differential is little, if any, in excess of that which obtains with a rear axle of the usual type. It is suggested that this is due to the fact that with a differential gear scraping of the tires results from wheel spin when one wheel only bumps, a happening that is avoided with a solid axle.

"If the 'differentialless' axle were adopted it would be necessary to arrange a clutching system to enable one wheel to revolve free if required, a small hand lever, similar to the gear change lever, and located in front or at the rear of the brake and hand levers, and actuating a dog clutch, being a likely arrangement. Thus, when the car was moved by hand, as in garage maneuvering, the one wheel would be released. It could also be freed even in the smaller maneuverings under power, such as backing into awkward corners, etc., etc. The saving in unsprung weight, resulting from an arrangement such as is outlined in the foregoing, is a strongly favorable point, apart from great saving in cost.

"The axle lay-out illustrated is still rather complex, and little in advance of the usual schemes, although a certain economy in fitting and erecting costs has probably been effected by arranging the differential box with separate sides, so that the bevels and differential gear may be erected and adjusted before the axle tubes are bolted up. In any case it seems impossible to effect sufficient economy, if the usual scheme with differential is followed at all, so that the rear axle without differential, or even a substitute, appears to be the correct arrangement in the circumstances. With a dog clutch, as already outlined, a practical working scheme should be evolved."

Some Comments

Regarding the combined casting for engine and transmission, it has not been the experience of either European or American engineers that the one-piece transmission and en-

Galvin in Sunbeam winning second heat after close race

gine is as cheap as the divided units with a bell housing attachment. The large castings are much more difficult to make, more troublesome to handle, and more costly to machine than the separate parts. The extra labor in assembly consists merely of doing up a dozen nuts, and the greater ease of putting in the gear and clutch parts separately from the engine assembly much more than offsets the saving in coupling the two portions.

One of the most interesting points is the suggestion for a torque tube as this would certainly cost more than would a Hotchkiss drive with half elliptic springs. The half elliptic springs, being lighter, would be intrinsically less costly.

Aluminum Powerplant

Another thing which is well worthy of note is the use of aluminum for the power plant, cylinder, crankcase and gearbox. This is absolutely new to British practice and is quite foreign to American cheap car convention. It means that the lower cost of upkeep obtained by lighter weight is thought so valuable as to offset the great saving possible by using cast iron instead of aluminum.

However, the most interesting thing of all is that this idea of what an $800 car should be contrasts so strongly with the sort of car an American manufacturer could put on the British market at this figure. Any manufacturer who in America is making a car selling for $650, could start a British factory on a 20,000 output, and reproduce his American model for $800 or less, quite easily. Putting it another way American production men and American engineers could show a British factory how to make something far less unconventional for the same money.

The author constantly mentions the fact that the car should not be finished too highly, that it must have no needless money lavished upon it, which means that he does not intend to give a better finish than that customary on the $650 class of American car. If this is so, then the cost ought to be less than the amount stated, if proper methods of production are employed.

Resta Easily Wins Speedway Grand Prize

Ralph De Palma Out Early in Race—Struggle for Second Place in Finals on Chicago Track

CHICAGO SPEEDWAY, Aug. 19—Dario Resta had a walkaway in the American Speedway Grand Prize Race held here to-day. With Ralph De Palma in his Mercedes out of the race early in the day, no competition remained to push Resta to anything like a close contest. The race was run in heats of 20 miles, the winners participating in the 50-mile final. Resta drove against a field that he apparently did not fear and after taking the first heat of 20 miles in 11 min. 42.6 sec., he easily won the 50 mile final at an even 100 m.p.h. The afternoon netted him $5,000 of the $10,000 prize money.

It was a close contest in the first heat for three laps between De Palma and the Peugeot of Resta. Then a cylinder head on De Palma's Mercedes blew out and after that it was all Resta. The fight for second place in the first heat was between Galvin in the Sunbeam and D'Alene in a Duesenberg who finished respectively second and third. Resta's average for the 20 miles was 102 m.p.h.

One of the best battles of the afternoon was found in the second heat, which Galvin took in the Sunbeam in 11 min. and 37.72 sec., or about 5 sec. faster than the heat won by Resta. Galvin's speed was 103 m.p.h. Lewis in the Hoskins made Galvin give his mount all it had in it and there was a margin of less than a car length between Galvin and Lewis at the finish. Galvin, Lewis and D'Alene ran one, two, three all through the second heat.

Lewis took the third heat in 12 min., 7.3 sec., his average being 99 m.p.h. D'Alene and Buzane, both driving Duesenbergs, were second and third, respectively all through the third heat. The fourth heat went to Buzane in 12 min. and 27.68 sec., his speed being 96.5 m.p.h. D'Alene crowded the little Greek hard, but could not head him. Milton brought his Duesenberg to the pits at the end of 14 miles in the fourth heat and Christiaens docked his Sunbeam at the end of 10 miles. The Belgian was having considerable trouble to

Four-Wheel Drive for Heavy Tractors

By W. F. Bradley

Special Representative of the Automobile on the French and English Front

Renault tractor near the front pulling a heavy field piece up a steep incline

PARIS, July 29—From the time guns were invented until the opening of the present war, the only known means of hauling artillery was by horse traction. In the various small wars prior to the present war use had been made of armored cars, carrying machine guns or very light artillery, but there does not appear to have been a single instance of the use of the internal combustion motor for the haulage of heavy artillery. So far as the French army is concerned, it was only on the eve of the war that the military authorities had finally decided on the adoption of the four-wheel-drive tractor for hauling big guns. Although the type was well developed when war broke out, it is certain that the number of tractors in existence was small, and the number of officers and men trained to the use of mechanically hauled artillery was very restricted.

It is not necessary to state in what proportions horses have been replaced by tractors in the present war. This much is certain, however; all the more difficult artillery work can be done by gasoline tractors better than it can be performed by horses, and there are no positions accessible to horse teams which cannot be reached by mechanical means.

Notwithstanding this, military experts are of the opinion that the horse will always be retained for certain classes of artillery work, notably for the haulage of the lighter guns. It must be remembered, too, that it is easier to convert material than to change officers and men. Long training makes it possible for men to get better results out of old-fashioned material than it would be possible for them to secure for a certain length of time with a more modern and efficient material.

There is no secret about the types of tractors used in the French army. They were all described in detail early in 1914—before the war clouds had begun to form—and they have only been changed in detail since then. To the four French makes, Panhard, Renault, Latil and Schneider have been added the Jeffery quad and some Holt caterpillars. It is not possible to make close comparisons between the Jeffery quad and the three leading French makes, Panhard, Renault and Latil. The Jeffery is a light tractor without a winch not primarily designed for war conditions, and only capable of being adapted to the haulage of light artillery over made roads or moderately easy country. There are many conditions such that the most powerful tractors can only reach commanding positions by hauling themselves up the hillside by means of the winch and then hauling their guns or trailers up in the same way. The Jeffery type has its own field of usefulness, but is not built for this class of work.

Jeffery Quad on a 30 per cent gradient

Expert opinion tends toward the belief that the final type will be the four-wheel-drive tractor similar to the Panhard, Latil and Renault. Owing to its lower pressure per unit of area the caterpillar can travel over soft ground inaccessible to the four-wheel

driver, but this advantage is offset by its destructiveness of made-road surfaces, and officers who have had charge of both types for hauling artillery boast that with their four-wheel drivers they can do anything possible with a caterpillar.

Another type of tractor is represented by the Knox, Fiat and Isotta-Fraschini in Italy, and the Daimler-Forster in England. All these have been used in the war and important data exists regarding them. They are all, however, rear-wheel drivers, and as such incapable of doing some of the work possible with the four-wheel driver, or, as the French term them, total-adherence tractors.

All the four-wheel drivers mentioned above drive and steer at both ends. For a given wheelbase they have a turning radius considerably smaller than that of any rear-drive truck. There are, however, disadvantages in steering at both ends, for it sometimes happens that on very difficult hills the front wheels will get in one track and the rear wheels in another, making it a very difficult matter to move the vehicle. Such a condition only arises with the combination of a very steep hill, rough surface, and no width to turn. Because of this, one firm has produced a four-wheel-driver steering at the front only.

Training Tractor Crews

An interesting feature in connection with the four-wheel-drive tractor development is the training of crews to handle these vehicles. Quite independently of its truck and touring car schools, the French army has a special organization for the training of sub-officers and men in the driving and handling of tractors attached to heavy batteries. While it is comparatively easy to train men to handle ordinary trucks on made roads, and not exceptionally difficult to transform an intelligent soldier into a first-class chauffeur, it is a somewhat elaborate process to produce men capable of getting the best results out of tractors.

It is the conviction of the officers in charge of this school that a four-wheel-drive tractor can go anywhere, providing the surface is sufficiently resistant to carry the weight of the vehicle. But to pass through a forest, to climb over clumps of trees, to get up a 30 per cent gradient of natural earth, to slide a gun down a 60-deg. embankment and haul it out again calls for considerably more experience than the turning of a steering wheel and the moving of a couple of levers.

While many of the men received at the tractor school have had previous automobile experience, every profession and every grade of life is represented. A glance over the dockets of the men received for training revealed a comic artiste from the Folies Bergere music hall (incidentally he contributed to the gaiety of the army), an opera singer, a professional photographer, a working tailor, a solicitor, a footman, a taxicab driver, and a man of independent means. Naturally their ability is varied, but the material being of good quality and a spirit of emulation existing among the men, it is possible to make them all fit for artillery tractor service.

If the pupil has never previously driven an automobile, it is found that 15 days' instruction on an ordinary truck are sufficient to make him a passably good driver. After this he goes to the tractor section, and at the end of 3 weeks, on an average, is fit to be sent out to the armies in the field. In addition to his personal record card, each pupil entering the school is given a progress card divided into thirty-one numbered squares representing the days of the month. At the end of each day the number of points accorded by the instructor is recorded on the card, thus forming a permanent record of the progress made by the man during his stay in the school.

The driving instruction is of an intensely practical nature. In the neighborhood of the school is a large amount of very hilly forest land with a clay soil difficult to operate on after rain. The tractors distribute themselves in this forest, each vehicle having a dozen pupils aboard and being in command of a couple of sub-officers. The superior officers move about from group to group, supervising the general work and giving instructions as necessity arises.

When I was introduced to this school two Renault tractors were coming along a mud track by the side of a lake. Although weather conditions this day were fairly good, there was about 8 in. to 1 ft. of mud before solid earth was reached. A sharp right-hand turn brought the tractor into the forest, on a narrow, steep track just wide enough for one vehicle. The gradient being only about 10 per cent, the tractor worked its way along slowly, with a trailer in tow, without any difficulty.

After the 10 per cent gradient came a level portion, then a 32 per cent gradient for a distance of 150 yd., the track being rough earth with either high banks on each side, or thick forest growth. The trailer was unhitched and left at the bottom of this hill, the tractor advancing alone and paying out cable as it proceeded. The differential was locked, the sprag was dropped and two of the crew placed behind with big blocks of wood to scotch the wheels. On the most difficult portion a partially choked gasoline feed pipe caused a stoppage of the motor and necessitated quick work on the part of the men with the blocks of wood. When the full length of cable had been paid out the brakes were set, the wheels blocked and the winding drum put into engagement. Slowly the trailer was hauled up, the instructors meanwhile giving attention to the men who were handling the cable on the capstan and the winding drum, and also to the crew of the two men aboard the trailer. With only a few yards to go, and while on the steepest portion of the hill, the cable snapped. Quick work with the brakes prevented a mishap and the incident was taken advantage of to give a lesson in making knots.

The climb was accomplished with locked differential and chains on all four wheels. The previous day, after heavy rain, it had only been possible to climb this hill by the use of block and tackle attached to a stout tree, and when the first tractor reached the summit, it had to help haul up the second one.

Owing to the narrow width available, it is doubtful if horses could have got any load up this hill by direct haulage. In any case, animal traction would have been much longer and would have required a greater force of men than mechanical traction.

Rough Work in Training

After some work under easier conditions, but all over forest dirt roads, the crew was taken to a hollow resembling a huge shell hole. Here a Jeffery was found at work with a number of sub-officers who were being given a superior training to fit them for the handling of tractor crews. Here an officer gave a demonstration of how to take advantage of the nature of the ground. Sliding the tractor down the steep bank until it looked as if the tractor would stand on its nose, he attempted to come up the steepest portion of the bank. The first three attempts failed, the tractor attaining an inclination between 40 and 45 deg. and the motor then stalling. The causes of the failures were pointed out for the benefit of the pupils and other attempts made until after considerable difficulty the Jeffery reached the top of the bank. The private soldiers then went through the same tests with a Renault and a Latil tractor.

To get as near to actual war conditions as possible, a heavy gun was taken into a hollow assumed to be a suitable emplacement for firing on a distant enemy and the pupils instructed how to get it up a 60-deg. banking with soft surface and only just sufficient room to pass between the trees. This maneuver could only be accomplished with the use of a couple of tractors, both using their winches, and a considerable

Sometimes it is necessary to haul the vehicles over mere wagon trails

amount of block and tackle. It was explained to the men how to place the tractors and the tackle so as to use the available power to the best possible advantage. While some of the easier driving tests are being carried out, those members of the crew not required aboard are left at some convenient point and given a lesson in making knots, in splicing, and in fitting up block and tackle, for it is recognized that much of the value of a tractor lies in the ability of the men to use the machine intelligently.

Sub-officers, who will later command tractor teams, are given an entirely separate training. It is required that these men shall be really skilled drivers capable of taking a tractor over the wildest kinds of country, and capable of giving an example to the men of both skilled and daring driving. Great attention is also paid to their theoretical instruction, lectures being given them on the application of tractors to the haulage of artillery, and they are also made to spend a few weeks as apprentices in the factories manufacturing the army tractors. It is thus certain that they will possess a complete mechanical knowledge of the vehicles which will later be placed in their charge.

When an artillery battery is motorized it becomes entirely dependent on gasoline for its ammunition and other supplies. Thus during the period of training it is not necessary to haul a gun on every occasion; cases of sand can represent shells, food, gasoline, chains and other equipment which, under actual war conditions, must be taken to the gun with unfailing regularity.

Conferring Life Through Care of Finish

By M. C. Hillick

MORE care of the finish and longer life for the car is a shibboleth that may well be observed in an attempt to keep it from going prematurely to the scrap heap. This is the day of the metal car body, principally sheet steel, and it requires no chemist to tell us that rust and corrosion, once developed upon the surface, gnaw remorselessly at it until the metal collapses and buckles under the strain. To prevent this result is the chief concern of the car owner and the car maker, for in the last analysis the manufacturer profits best by making his products to wear to the utmost.

Grant that the brand new car comes from the manufacturer well painted and finished, and in other respects is a credit to his skill and reliability. It is bought by some one who takes pride in keeping the car in fine condition, and he starts out with that purpose in view. Lack of information of a practical nature leads him to neglect some of the vital points in care taking, with the result that rust starts at some of the exposed parts of the surface. The methods of prevention are simple but indispensable. The cure, if any, is correspondingly difficult. First, constant attention to the needs of the surface. The sheet steel, even when buried under the weight of much paint and varnish, requires constant watching, for here a little and there a little, the waspish sting of the rust nips at the metal, finds a niche to cling to and keeps on nibbling.

To begin, scrape the rust clean from the surface, using for the work a hook scraper and some emery paper, cleaning off all the corrosion and preparing a foot-hold for the rust-inhibitive metal primer. Touch the afflicted part with this material, and let it dry thoroughly. In due time fill the cleaned-out spot with enough hard drying putty to make the depression level with the surrounding surface. When this putty, applied smooth to lessen the labor of sandpapering, is dry, bring it down smooth and fine with sandpaper, and then coat with some of the body color, making the first coat to dry "dead"—that is, without gloss of any sort. Apply a second coat into which is stirred enough varnish to develop the necessary luster. Then when this coat has dried cuff the gloss off to match that of the finish, using for the work a piece of plush moistened in water and flicked across a bit of pumice stone flour to increase its erosive effect.

The above class of work may be performed by the car owner or the chauffeur, none of the details being too technical for the lay mind to master, nor the processes too intricate to accomplish. By keeping a close check upon the appearance and wear of the car, and taking any outbreak of the surface at its initial stage, the wear of the surface may be greatly prolonged, with the best feature of the finish consistently maintained throughout the life of the vehicle.

Rust May Develop

Perhaps the question may be raised as to the tendency of the cars with the oven baked finish to show rust development, etc. At the edge of panels, about the moldings, and where laps occur, there one needs to look sharply for corrosive manifestations, for here dampness finds a foot-hold and rust appears. Therefore, in addition to the prevention here indicated, take advantage of other precautionary measures, chief among which are the following: Light, ventilation, washing and renovation, and storage quarters.

The newly varnished car may safely be washed with clean, cool water which will serve to harden the varnish and increase its brilliancy, and keep it from spotting when used over muddy or dusty highways. When it is deemed desirable to use a feeder for the varnish—in a word, to renew its diminishing powers for service—then resort may be had to some of the reliable renovators and polishes now available. Use these mediums with judgment, and as often as the requirements of the service suggest, bearing in mind, meanwhile, that no renovator or polish is qualified to take the place or do the work for which the varnish of efficient and capable composition is designed.

Secret of Aluminum Piston Success

Errors in Design More Serious with Alloy than with Iron—Service Depends on Correct Proportions and Correct Alloy—Modified Theory of Side Pressure Distribution

By A. Ludlow Clayden

THE aluminum alloy piston has just completed its first year of usage as a stock part of an automobile. Thousands have been made both by the sand-cast and the permanent mold processes; tons of aluminum are to-day reciprocating within the cylinders of American automobiles. That the aluminum piston has been an absolutely unqualified success is only true in the cases where all the conditions have been correct. There have been troubles due to many different causes, but these troubles have been of a character which has allowed engineers to perceive the reason and to avoid it in future. Some manufacturers have had no trouble, others have had a good deal, but the average experience has been quite satisfactory. Considering how new a thing it was a year ago, the aluminum alloy piston has established itself with much less difficulty than most novelties, the set-backs have been comparatively few and their causes readily traceable.

Importance of Right Alloy

Among the many alloys used for casting pistons there are all sorts of mixtures of metals. Most alloys are kept a secret by the foundry firm which owns them, and most firms have now discovered the best alloy for piston purposes. It is a metallurgical question, complicated by the desire to cast as thin as possible so as to avoid wasting the precious metal in machining, and it is not yet possible to say that just such and such a mixture is the best for all purposes. It would be absurd to deny that wrong alloys have been used in the past year in some cases. A good many pistons did get out with too soft a metal, and these pistons have worn rapidly, too rapidly to make them commercially satisfactory. The bulk, however, have been of better material, harder and much more durable, and it is safe to say that hardly a casting firm in the business but knows more about the proper alloy and the proper method of casting than it did a year ago.

It is particularly noteworthy that the troubles due to wrong alloy have been almost all shown up by rapid wear and not by failure. Absolute fracture has been an uncommon fault. This means that engineers and aluminum experts do know the proper proportions for strength, that they knew them a year ago in fact; what remains to be settled finally is the best metal for surface durability and not the best metal for strength. If we can get the surface hardness the strength will be satisfactory with normal design for the parts exposed to stress.

Engineers are perhaps a little apt to forget that an automobile piston has two functions to perform. It has to transmit the driving force of the expansion and it has also to act as a crosshead. In a steam engine the piston is purely a piston, the crosshead which takes the side thrust of the connecting-rod is a separate part, better suited for its work than the piston itself. Light weight and limitations of possible height, together with the desire for simplicity, make a crosshead for an automobile engine altogether out of the question; it would be an absurdity, but having thus discarded the crosshead it must not be forgotten that the functions of this part have merely been transferred to the piston and the latter must therefore be designed once as a piston and once as a connecting-rod guide.

Gas engines of the stationary type have always had long, heavy pistons with a very large surface in proportion to the expansion thrust on their heads, so large a surface that the unit side pressure due to connecting-rod angularity is very small and durability correspondingly great. The early automobiles followed the gas engine and their pistons were designed in accordance with gas engine rules, but it was soon discovered that the length and weight of the piston could be cut down without trouble; the factor of safety of the gas engine was unneccessarily high for an automobile motor. Simultaneously a desire to reduce the bulk of the whole engine led to a general shortening of connecting rods, thus increasing the side pressure due to the angularity, and at the time of the introduction of the aluminum piston we had practically reached the limit of small piston surface and great connecting-rod angularity possible for iron pistons.

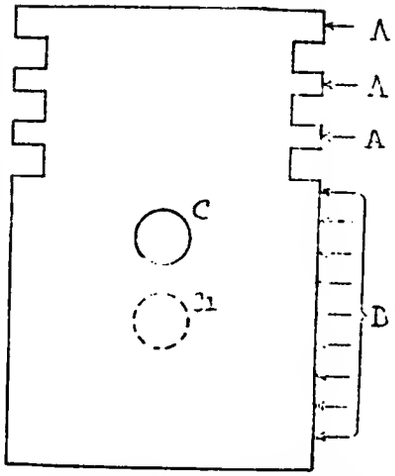
This being the case it was manifestly impossible simply to substitute a softer metal for the already very highly stressed iron; such a procedure was to court failure, yet many engineers took a chance at it. Those who did so and had no trouble really proved that their iron piston was larger surfaced than it need have been. The absolutely correct proportion for iron cannot be also the correct proportion for aluminum alloy.

Equalizing Side Pressure

In the design of pistons it has been a rule in gas engine practice to take moments about the piston pin, and to arrange the pin so that it is at the center of balance; *not* the center of the piston. The rings are neglected and the piston is regarded as touching the cylinder on the lands between the rings and over the skirt. A calculation on this basis will then enable us to locate the piston pin so that the unit side pressure between piston and cylinder wall, due to connecting-rod angularity, is the same at every point of contact. Neglecting the spaces occupied by the rings this will make the correct position for the piston pin a little below the center of the piston length. This is partly offset by the effect of friction which causes the proper position to be above the center, so, following gas engine practice, the pin position commonly is very little removed from the middle of the piston length, with the short automobile type of piston.

Now this assumes that the piston touches the cylinder on the lands between rings, and there is very grave doubt if this is ever the case in automobile practice. Firstly, the expansion of the head has to be allowed for to an extent which makes it impossible for the first land above the top ring ever to touch the wall. The case of the second and third lands is little better, in fact the clearances recommended for modern high speed engines are such as to prevent these narrow bands of metal from coming in contact with the cylinder. Thus, instead of neglecting only the spaces occupied by the rings, we have to neglect the whole

part of the piston which carries the rings. If there are three rings ¼ in. wide and ¼ in. apart, and the top ring is ¼ in. below the top of the piston head, there will be six ¼ in. which do not touch instead of three ¼ in. allowed for by the old formula. This means that when we begin to figure the piston as a crosshead we should imagine it cut off at the bottom of the lowest ring groove. Then we are left with the skirt, then add on top of it such rings and ring grooves as pin comes out at just a trifle above the middle of the skirt. In other words, we design a crosshead consisting of piston skirt, then add on top of it such rings and ring grooves as we think are necessary.



This shows the two ways of figuring the piston pin position. Including the arrows A (that is including the patches between the rings) the pin position to give equal unit pressure is the upper position shown. Neglecting all the ring-carrying part of the piston the position of the pin works out as shown in the lower place. Of course this is just a diagram and not in strict proportion

It is instantly obvious that the effect of this method of treatment is to increase the distance between the piston pin center and the top of the piston, which means that the height of the whole engine is increased a little unless we allow the bottom of the skirt to come well out of the cylinder at the bottom of the stroke. There is no harm in doing this, as the piston has little guiding to do when nearing the bottom.

If this new way of attacking the problem is the correct one, and there seems every reason to think that it is, then we must abandon the idea that the length of a piston should bear any definite proportion to its total length. Rather it may be suggested that the part of the piston below the rings should bear a proportion to the bore. For example, it is possible that a length of skirt or contact portion of piston should be provided equal to the bore. Possibly a little less than this is sufficient, but in a general way it is probable that length-bore is about right. With ¼-in. rings this means that the total length should be equal to the bore plus about 1½ in. for the ring carrying portion. Another possibility is that we may be able to place the rings closer together, having given up all idea that the lands between the rings have any function as a guide. For example, with ¼-in. rings it may be enough to allow 1/16 in. between each ring and ⅛ in. at the top. This adds up to 1 3/16 in. as against 1½ in. Experiments along this line are expected, so it may be found that it is possible to get sufficient guiding surface without a piston of *much* greater length overall than the present practice.

Effect of Expansion

Another matter that is affected by the precise alloy used is the clearance required. Some alloys have a much greater rate of expansion than others, and this means they require a correspondingly greater clearance. Luckily it appears to be the harder and better wearing alloys that have the smallest rate of expansion. Here again the dual function of the automobile is the thing which is causing the trouble. If the lower part of the piston which is really only a crosshead could be kept at a constant temperature it could be made a close fit in the cylinder and there would be no slap. Thus attempts have been made to so separate the head part carrying the rings, and the skirt part acting as the crosshead in such a way as to prevent the conduction of much heat from the head to the skirt. The earliest example of this sort of construction is, of course, the Zephyr steel piston which had a head and a skirt connected by a small diameter column in the middle.

Summing up the present situation regarding the aluminum alloy piston it may be said that every one wants to use it, but we are not yet able to state exactly how it should be designed to give long wearing qualities. In a year of use the question of the right alloy has been fairly well settled, and there are several alloys which are entirely satisfactory. We now want to find some means for reducing the unit side pressure, and some means whereby the clearance can be reduced a little more. Possibly the long piston is the answer, possibly some special form may arise that will be still better, but present appearances are strongly in favor of the long piston as the most probable answer.

—

A Chance for Invention

ONE conspicuous blemish on nearly every seven passenger car is the two slots in the tonneau carpet which occur where the support of the folding seats goes through into the floor. However neatly the seats themselves may stow away into the back of the front seats, and many do now disappear completely, their presence remains obvious as long as the carpet has to be cut. In fact, the slits in the carpet are made all the more prominent by reason of the complete disappearance of the seat itself.

If the "leg" of the seat came away from the floor altogether and stood in a socket, this would not be such a disfigurement to a fine car as the present carpet slits.

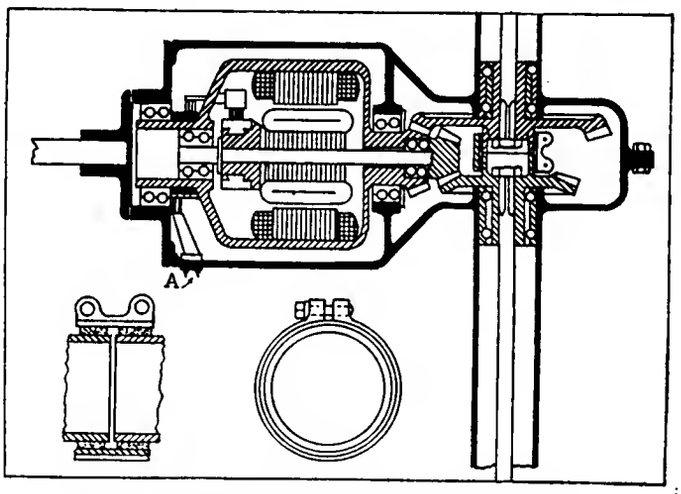
—

A Novel Drive for Electric Car Axles

A NOVEL rear axle drive for either electric cars or gasoline-electric has been invented by L. J. Monahan, mechanical engineer, Oshkosh, Wis. The apparatus comprises an electric motor mounted on the rear axle, the armature connecting one axle section by bevel gear and the reversely revolving field element connecting the other axle section so that the combination forms virtually an electrical differential.

A feature of importance is the frictional device which is located between the axle sections. This is shown in Figs. 2 and 3 and is for the purpose of preventing too easy a differential action which would take place with this free operating drive. The frictional bands allow slippage for corner turning but place a burden upon one wheel which prevents it from slipping too easily, thus providing internal differential friction.

The current is fed to the motor through the collector rings *A* and reversing action is given by a reverse current switch.



Section through axle with electric motor differential

Kissel All-Year Town—Victoria Body

Sedan and Coupe Types Continued and Now Mounted on the Smaller Six—Elm, Ash and Steel in Bodies and Tops

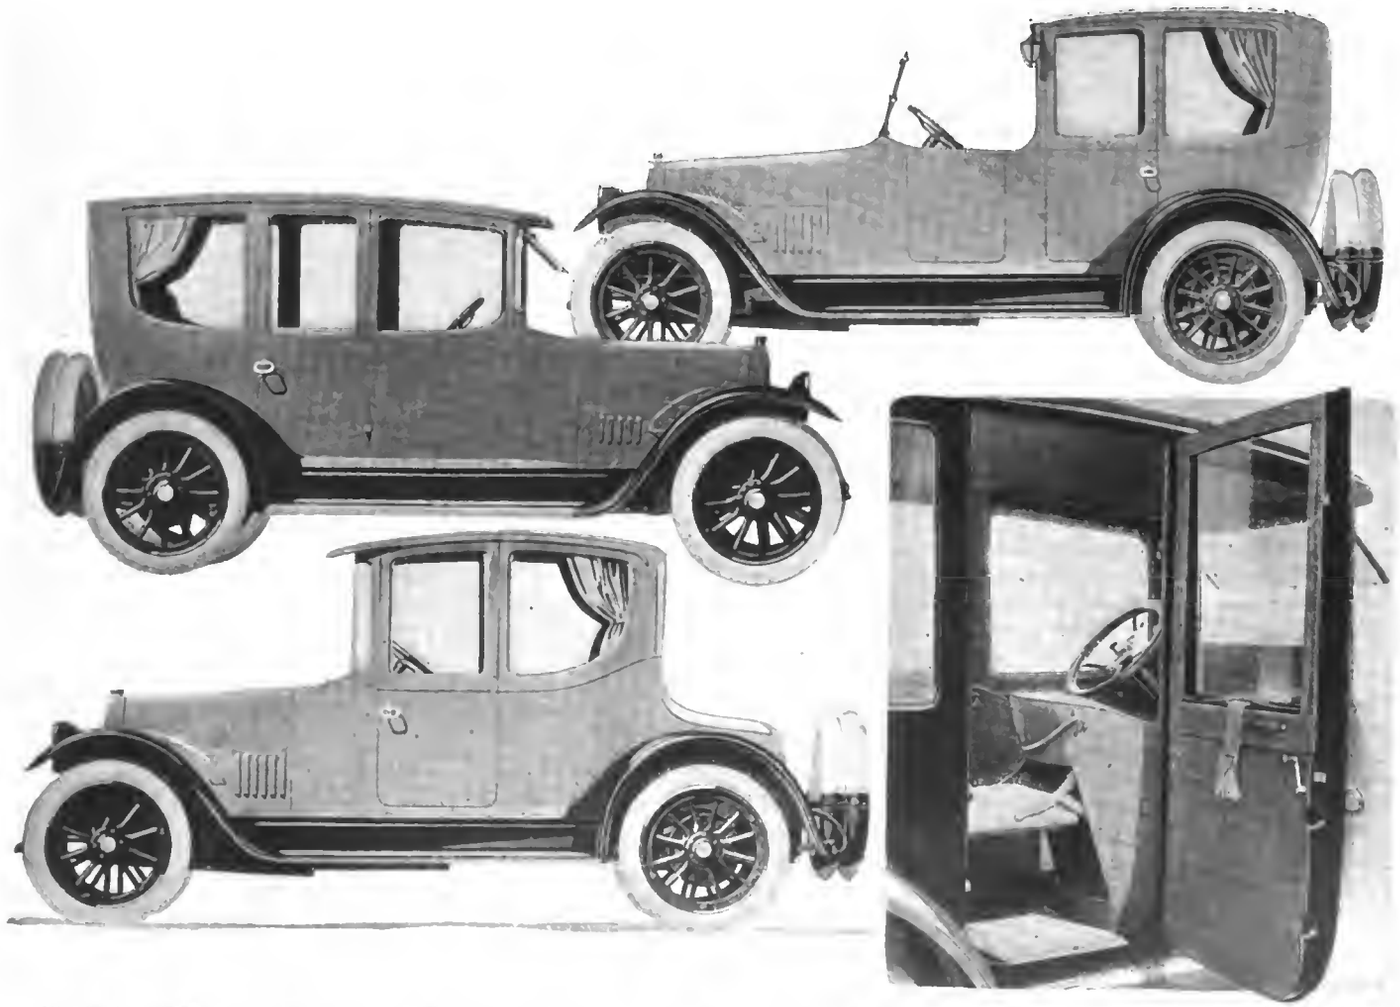
FOR the winter of 1916-1917 the Kissel company has brought out a number of its improved All-Year bodies for the chassis model marketed under the title of Hundred Point-Six. This is the smaller of the two Kissel sixes and the larger one will also be equipped with the All-Year tops as before.

The new top line includes the sedan and coupé designs which were marketed last year and in addition a town car top mounted on a victoria body. The price of the sedan and coupé bodies is $1,520, while the victoria town car lists at $1,850. These bodies are about the same in construction as those of last year. They are featured by their easy convertibility from the open to the closed type, thus allowing the owner to have all the benefits of two cars for practically the price of one.

Selected white ash and elm is used for the main and door frames of the detachable top with a covering of sheet steel. The roof is three-ply paneled white wood under heavy duck canvas laminations. French plate glass is used for the windows, and these are set solidly into hard rubber to prevent leaks and to eliminate rattles. The standard tops are leather lined and special cloth lining can be secured at additional cost.

The body and the top are connected at ten points by means of rectangular bolts fitted into sockets which are arranged to prevent any projections from marring the appearance. Between the body and the top there is inserted a layer of felt anti-squeak material. In attaching the top the electric wiring is connected automatically by spring plungers. The winter bodies are all equipped with dome lights operated by push buttons.

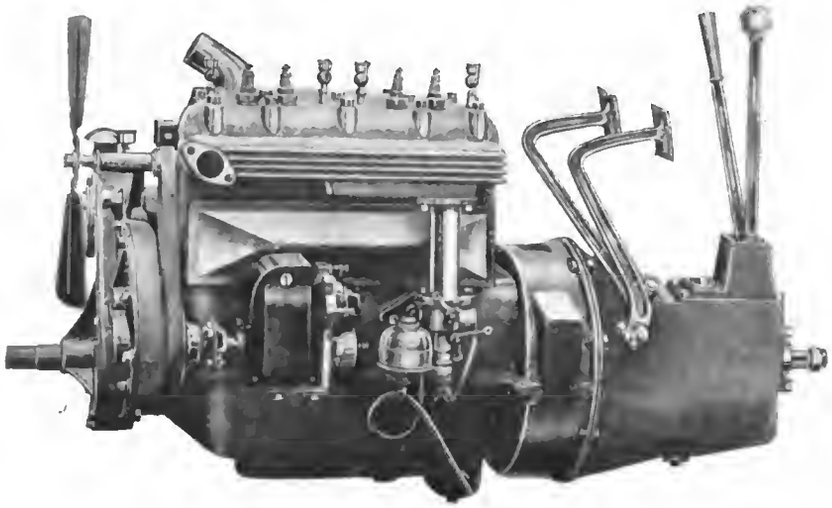
All the Kissel bodies are fitted with divided front seats, a wide corridor being provided, allowing for easy passage. Seventeen coats of paint are used, requiring twenty-two finishing operations. The hinges are pressed steel and are concealed. Ventilation is secured by dropping the windows into the lower halves of the doors.



Illustrating the all-year bodies which will be mounted by the Kissel company on the small six known as the Hundred Point model. This is the same line of bodies as was marketed last year with the addition of the Town-Victoria body shown in the upper right. The center body is a sedan-touring and the lower a coupe-roadster. All of these are convertible types, changing the car from a summer to a winter job in a short time

Rainier Delivery Car Ready Soon

Passenger Car Maker Enters Truck Field With 1000-lb. Wagon to Sell for $850. Chassis Assembled from Standard Units



Unit power plant used on the Rainier 1000-lb. delivery wagon

JOHN T. RAINIER, who used to make passenger cars is now associated with P. N. Lineberger, in the manufacture of a 1000 lb. delivery wagon to sell for $850. Production will start in October on this car car which is to be known as the Rainier. This is the first time this name has been linked with a motor vehicle since the absorption of the Rainier interests by the General Motors.

While of conventional design in the main, there are points in general appearance which are distinctive. The radiator, is a reproduction of the Rolls-Royce form. It is high, as is the square, blocky hood, which gives a good head of water above the motor for the thermo-syphon cooling system. The hood is of the three-part type with top and sides separate, snap fasteners being located at the eaves, such as found in big trucks.

The frame has been carried very low and all of the way back to the tailboard, to eliminate any body overhang. The cab floor hugs the frame closely and with the foot-board and dash is a single steel stamping. Fenders are wide and follow the curvature of the wheels in the approved style. Running-boards extend the full length and are covered with aluminum. The tubular bumper at the front is secured to brackets integral with the front spring horns.

Load Space 74 in.

Tires are 33 by 4-in. all around, and mounted on demountable rims. The 115-in. wheelbase permits of the use of larger bodies than is customary on ½-ton cars and this has been taken advantage of by the design of a number of distinctive body features as for instance, the length of 74 in. of load space back of the driver's seat.

The engine is a block-cast unit of the high-speed type. It has two bearings and is very compact due to integral casting of the cylinders, crankcase and both manifolds. The cylinder heads are in a separate casting.

With a bore and stroke of 3¼ by 4½ in., it rates 16.92 hp. by formula but at 2000 r.p.m. it develops according to the makers, 28 hp. The crankshaft bearings are 2¼ and 2½ in. long, respectively, and the connecting-rods are drop-forged I-beams 9½ in. between centers with 2-in. crank-pin bearings. Mild steel against cast iron teeth helically cut serve to quiet the timing gears, their face width being ⅞ in.

Valves are to the left, their mechanisms covered by a single pressed-steel plate. They are 1⅝ in. diameter.

The Carter multiple-jet carbureter of 1⅛ in. size, bolts to the inlet pipe on the left side, just behind the Dixie magneto and has an air control on the dash. The magneto is driven from the timing gear-case by a leather coupling from the fan-belt pulley. It is fitted with a dash spark control.

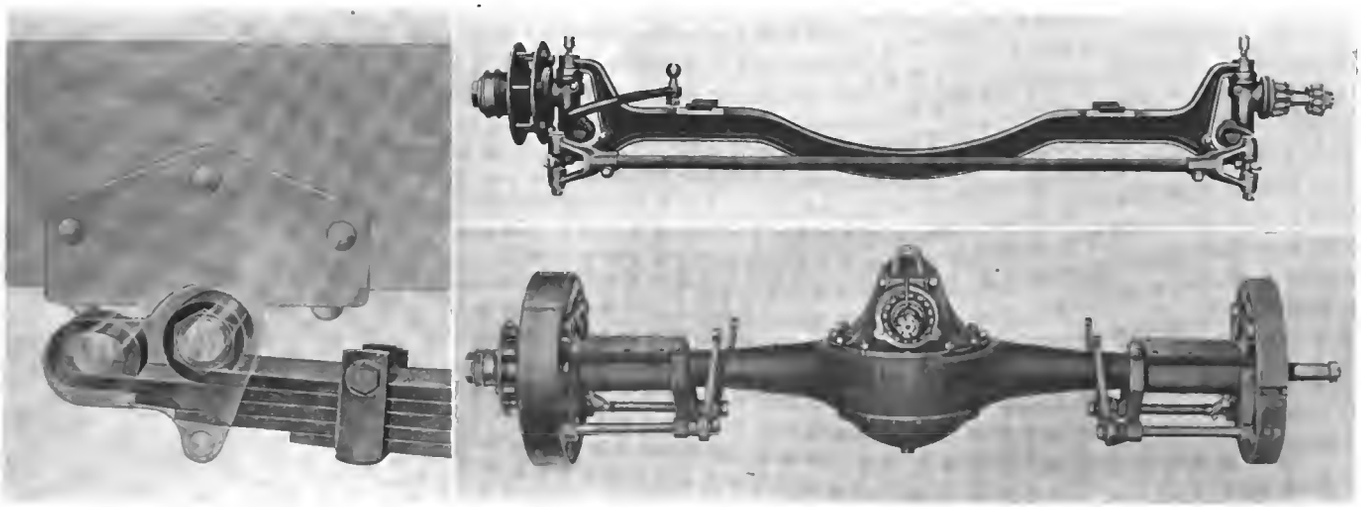
Splash Lubrication

Circulating-splash lubrication is employed, the oil being strained and pumped from the reservoir by a plunger pump eccentric-driven from the camshaft. This delivers the oil to troughs beneath the cranks. Overflow is fed by a pipe to a groove cut in the inner face of the camshaft gear, communicating with the gear teeth by holes drilled between them. Pockets also collect the splashed oil and direct it to the main and camshaft bearings. Excess oil splashed on the cylinders is prevented from causing smoking by holes drilled in each piston below the scraper ring. There is an oil gage on the dash and a level indicator at the side of the crankcase.

A Borg & Beck three-plate dry clutch drives the Grant-Less three-speed selective gearset. This clutch is adjusted by shifting two bolts. The gears are of nickel steel.

Final drive is through a shaft with two universals to the Timken pressed-steel worm-driven axle, Hotchkiss drive eliminating all radius rods or torque arms. The spring construction consists of a double-eye arrangement at the fixed front ends of the rear springs. The top leaf is provided with the usual bronze-bushed eye. The second leaf, instead of ending just below this eye extends beyond it and is bent to form a secondary elliptical eye which normally floats about an auxiliary pin. The third leaf extends out as far as the first leaf, so that 50 per cent more strength is said to be provided at this, the weakest part of a spring. In the event of the breakage of the top leaf, which ordinarily would make the operation of the truck impossible, the second pin and eye come into play, being otherwise out of action.

Typical body standard on the Rainier 1000-lb. commercial vehicle chassis



Some of the Standard units used in the assembled Rainier chassis which will be ready for delivery in October, according to the present plans of the manufacturers

Safety at this point is still further provided for by a side plate and a pin below the bracket. The rear springs are 50 in. long, extending back nearly to the end of the frame, and 2¼ in. wide. They have eight leaves. The front springs are 38 in. long, 2 in. wide and have seven leaves.

The frame is of unusual size, being 4½ in. deep, of 5/32-in. gage pressed steel, and properly necked in at the front to provide a short turning radius. This is a clear inch deeper than on some trucks of the same rated capacity.

The front axle is of Timken make, I-beam type, of 2½-in. section, having nickel steel steering knuckles. The steering gear is at the left, of Gemmer make, with an 18-in. hand wheel. The throttle lever is below the wheel, of the same type as applied to Renault cars. The throttle is principally controlled by a foot throttle. The levers are in the center of the cab.

Standard equipment consists of one extra rim, three oil lamps, the front lamps being attached to the rear of the dash, with their lenses flush, a Long horn, a tire pump, jack and full set of tools. Electric lighting and starting will be applied for $85 additional.

Several standard bodies are offered, modeled upon the designs used by leading New York department stores. The open express type, 74 in. long and 44 in. wide, known as Model E sells for $100.

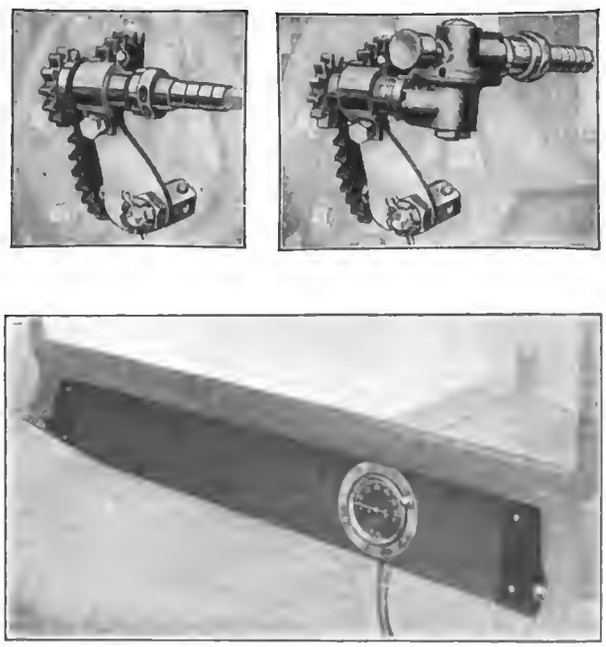
Standard painting is in contrasting colors, special painting being charged for extra. Regularly, Model E, the express body type has a green body with red crest panels, red wheels and black chassis, selling for $100, so painted. Model S, panel type, has middle and lower panels of blue, upper panels of black, red wheels and a black chassis, selling for $110.

New Ford Speedometer Easily Attached

THE Standard Thermometer Co. of Boston, Mass., has just brought out a new Ford speedometer combination consisting of an instrument board to fit in the cowl, flush mounted speedometer and flexible shaft mechanism.

The instrument board is covered with imitation leather and is cut out for the installation of the speedometer. It may be installed on the Ford car by removing one nut on each side of the dash cowl, slipping the metal and pieces of the instrument board over the bolts, and then replacing the nuts.

The installation of instrument board and speedometer can be made by any Ford owner without drilling any holes. The driving sprocket for the Standard speedometer is bored to fit the hub flange of the Ford car; the instrument board fits the Ford cowl and the speedometer head fits the instrument board.



Flexible shaft connections on wheels and new instrument board sold with Standard Ford speedometer

Two outfits of this type are at present being furnished for the Ford cars: Outfit No. F-330 consists of instrument board, flush type speedometer, 66-in. flexible shaft and case, and the Standard Thermometer Co.'s regular Ford drive with the new support which permits installation on any Ford car whether or not the steering arm may be drilled for speedometer installation. This outfit lists at $14.

Outfit No. F-355 is similar to the above with the exception that the drive is the Standard Thermometer Co.'s patented swivel type, which is particularly advisable for use on cars equipped with shock absorbers, as it removes the driving shaft from every possibility of collision with and damage by the shock absorber case. This outfit lists at $15.

The Rostrum

Speedometers Should Be Easy to Read

EDITOR THE AUTOMOBILE:—On page 179 of THE AUTOMOBILE for Aug. 3 appeared an item entitled Efficiency vs. Neatness.

There are 5280 ft. in 1 mile. If a car is moving at 60 m.p.h. it advances 5280 ft. in 1 min., or 88 ft. per sec. Roughly speaking, one and one-half times the mile speed per hour is the foot speed per second.

It is not when going slowly that the driver is most apt to be interested, but when speeding. Even at 20 to 30 m.p.h., he is moving at 30 to 45 ft. per sec.; if at 40 to 50 m.p.h., at 60 to 75 ft. per sec. What driver at such times dares take his eyes off the roadbed for ½ or even ¼ sec. to study the figures? If he desires to know the time of day, a quick glance at the clock is sufficient—the position of the hands tells him; the figures on the dial are of no consequence. It should be so with the speedometer.

There are speedometers made with black dials and white hands, but the designers could not resist the temptation to make them pretty; so they are delicate scroll work. Drop the pretty, and consider only utility—make the hands solid, straight bars, ⅛ in. wide, and charge them with phosphorus so that they will shine at night. With such an indicator, a furtive glance is all that the driver will ever need.

It would cost no more to have speedometers so built as to be easily read, if the manufacturers of automobiles would insist upon it when placing their orders.

This brings up another point. Every indicator on the dash should, regardless of appearance, squarely face the driver's line of vision.

Utility First is the elder of its twin brother, Safety First.

Retiming a 1905 Mercedes Car

Editor THE AUTOMOBILE:—I have a 1905 Mercedes which originally had a make-and-break ignition, which I changed to a high-tension. I would like to know what is the correct valve timing for maximum speed.

2.—What is the correct valve timing for ordinary running?

3.—Correct timing for the magneto in each case?

W. L. W.

Port Chester, N. Y.

—The changing of the ignition system from low-tension to high-tension should not affect the valve timing. In regard to ignition timing, it may make a difference. THE AUTOMOBILE has no record of how the 1905 Mercedes was timed when it left the factory, and if there are no marks on the flywheel or other parts of the engine gear showing how the engine was timed, it will have to be done experimentally. In doing this, it is well to work with the opening of the intake and the closing of the exhaust, allowing the closing of the intake and the opening of the exhaust to fall where it will with the shape of the cam contour.

First try letting the intake valve open at as near 10 deg. after upper dead center as possible. The exact number of degrees will depend on the timing gear and you will have to take the nearest tooth mesh to 10 deg. making what difference there is on the low rather than on the high side of 10. Then set the exhaust camshaft so that it will close the exhaust valve at about 5 deg. after upper dead center. With this as a starting point you can work the engine back and fourth a tooth at a time on both the intake and exhaust valves. It may be that the timing stated will be perfectly satisfactory.

2—The timing given under question 1 will be correct for ordinary running and up to as high speeds as you will be able to secure from this car. In general the rule for timing motors for racing is to push everything ahead. That is, both intake and exhaust valve openings and closings as well as the spark timing.

3—For ordinary running the magneto should be so placed that on full retard the spark occurs exactly at upper dead center. For racing the magneto is generally advanced one or two teeth.

Found Click in New Engine

Editor THE AUTOMOBILE:—What would be the most likely reason for a click in the engine of a 1916 six? This click

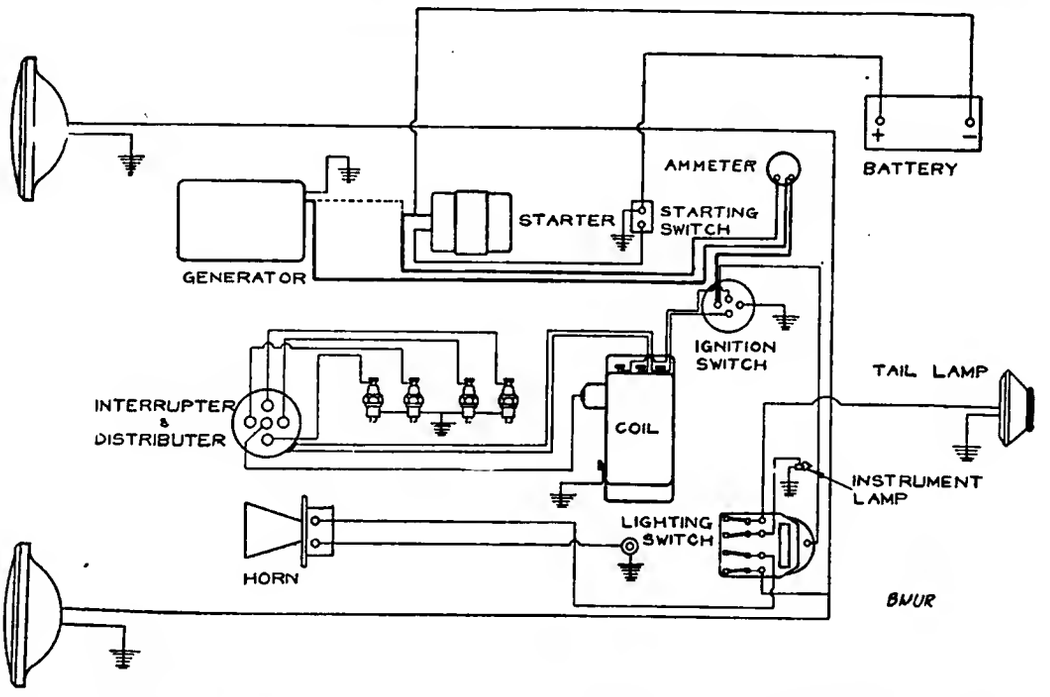

Fig. 1—Wiring diagram showing the installation of an ammeter on Hupmobile with the Bijur system

sounded like a valve tappet. The car was returned to the factory but they were unable to locate it so put in a new motor. Could it be that the camshaft was a little out of true?

2—Has the Buick company announced its 1917 sixes yet?

3—What is the bore and stroke of the Grant six, the Buick little six and the new Overland little six which was just announced?

4—Kindly give the names and prices of all three-passenger roadsters under $1,000 and state whether or not they are the clover-leaf type.

Waltham, Mass. C. H. B.

—It is quite difficult to state with any likelihood of hitting the truth which of the many moving parts of a motor would be most likely to make this clicking sound. An undercut cam, a valve stem which is too short, a loose piston, misaligned crankshaft bearings or faulty rod bearings are all possible causes.

2—So far, for the coming season the Buick company has announced the continuation of its present small six and in addition a four-cylinder car.

3—The bore and stroke of the Grant six for 1916 is 3 by 4¼. The Buick little six is 3¼ by 4½ and the Overland model 85 six is 3¼ by 4½.

4—For a complete list of body types and prices you are referred to THE AUTOMOBILE for Dec. 30, 1915, in which the price list of these cars was given. No lists have as yet been made up of 1917 cars as these are being announced by the manufacturers every day.

Needle Valve Probably Misadjusted

Editor THE AUTOMOBILE:—I have a 1915 model 37 Oakland touring car equipped with Maxwell carbureter. This spring I had the engine overhauled, put in new pistons, scraped out the carbon and ground the valves. The air valve broke off its hinge just before I put the car up for the winter, so this spring I sent that to the factory to have it overhauled and put same on after overhauling.

Now the engine runs smoothly at anything less than full opening of throttle and pulls well also, but when the throttle is opened first it pulls all right, too, but on a long pull holding it open all the way it will die down suddenly and commence to backfire through the carbureter. On a long pull in second it will do the same thing. This seems to be at speeds in excess of 25 m.p.h. in high and in excess of 18 m.p.h. in second. When it starts to spit like that and I release the throttle it will run smoothly, but, of course, the car will slow until I have to throw it in low, as it does not get the gas to push it. Have tried closing off air almost completely, also opening very wide, but am still puzzled. Can you help me?

A. T. McG.

Liberty, N. Y.

—Most probably your trouble is incorrect adjustment of the needle valve which controls the size of the nozzle. If this is wrong it cannot be compensated for by air valve adjustment. The gasoline nozzle setting is controlled by the thumb screw at the bottom of the carbureter directly under the flange where it attaches to the manifold. Try slacking this back a quarter turn at a time. The symptoms you describe are also occasionally caused by faulty spark plugs.

Putting Ammeter on 1916 Hupmobile

Editor THE AUTOMOBILE:—Kindly advise me how to install an ammeter on a 1916 Hupmobile roadster. If possible, I would like wiring diagram showing where to put the ammeter in.

Keene, N. H. G. P.

—The method of installing an ammeter on the 1916 series N Hupmobile will vary according to whether the electrical equipment is Westinghouse or Bijur. The accompanying illustrations, Figs. 1 and 2 show the installation for both these systems.

Changing National to Racing Car

Editor THE AUTOMOBILE:—I have a 1914 improved series V model National. It is now a seven-passenger and I would like to make a racer out of this car. Would like you to give me an illustration or two and some advice through your columns. I do not want to use the bucket seats but cut down the regular front seat and use it so that there will be some comfort to it.

Cutting the seat down, building the cowl and rear end is the parts I want advice on, also on lowering the steering gear.

I am in a position to do this work myself, also the metal work, cowl and stern. Where could I obtain fenders that could be fitted. I am counting on cutting the running-boards about half in two.

Helena, Ark. W. N. B.

—In building the cowl and tail, the point which must be had in mind is that the car presents no surfaces which would increase the wind resistance. Therefore, the cowl should be a continuation of the line of the hood, whether this line is curved or as it should be preferably, straight. The tail does not make such a material difference unless you are traveling at speeds above 80 m.p.h. Probably one of the best worked out streamline racing bodies in this country is that used on the Packard aeroplane racer shown in THE AUTOMOBILE for May 4, 1916.

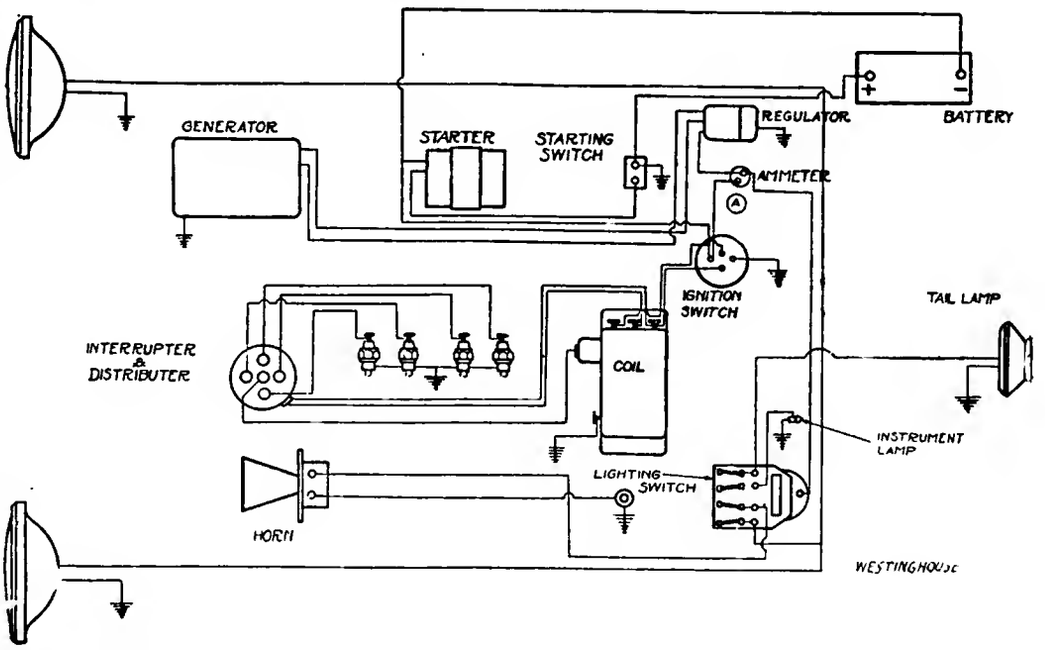

Fig. 2—Wiring diagram showing the installation of an ammeter on a Hupmobile with the Westinghouse system

The FORVM

ECONOMY OF THE SEMI-FLOATING AXLE DUE TO PRINCIPLES—MEETING THE DIFFICULTIES WHICH ARE TO BE FOUND IN THE TWO-CYCLE ENGINE

Semi-Floating Spells Economy

By A. M. Laycock

DURING the last few years the semi-floating axle has become very popular, not only in the passenger car field but in motor truck service as well, even up to 5 tons capacity.

However, there are still people who have very decided views as to the relative merits of the semi, three-quarter and full-floating rear axle. Perhaps it has never occurred to most readers that *the tonnage* of the world is carried on semi-floating axles.

All railway rolling stock, including locomotive, freight car and passenger coaches are operating on semi-floating axles. If we should subsitute the term—"fixed hub"—for semi-floating, as one of the axle manufacturers has lately announced, it might be better understood applied to railroad work, as all heavy rolling stock has the wheels keyed or fixed to the axle. In all railroad designs, the dead weight of the vehicle is carried on the axle itself, and the torsion as well; while every one can realize at a glance that the dead weight is carried on the axle, it is not so easy to grasp that there is a considerable torsion also.

On large European railroad engines, using inside and outside cylinders, it is quite easy to realize that torsion is present in the driving axle, and even with the conventional engine, using two outside cylinders; but with the passenger and freight cars, it is difficult to appreciate that considerable twisting takes place on the axle, but on rounding sharp curves when the outer wheel is running on a larger radius than the inner, the twisting moment in the axle is equal to the total weight carried multiplied by the radius of the wheel and the coefficient of friction on the rails which, when figured, amounts to a considerable torsional stress in the axle—in fact, absolutely in the same proportion to the twisting moment in the semi-floating 5-ton worm drive axle, as this is figured in the same way, particularly when propeller shaft brakes are used.

Advantage in Widely Spaced Bearings

Taking for granted that we have the combined bending and torsion in the axle with a fixed hub, the outstanding feature in favor of this construction for real heavy duty, lies in the fact that bearings are spread so very far apart—in fact, on most passenger and freight cars the bearings are on the outside of the wheel, and in European locomotive practice, with inside cranks, the bearings are always on the outside, while on the tender of the engine they are generally spread as far apart as possible. This, of course, greatly enhances the life of the bearings, as the unit pressures are so much lower, particularly when rounding curves when bearing pressures are maximum. It would be interesting to note what would happen to a full-floating axle taking curves regularly at 35 m.p.h. under these extremely heavy loads. We prophesy that the train officials would have an anxious time between hot boxes and time schedules.

Contrasting this heavy design with the full-floating type, where the bearings are spaced 4 in. to 6 in. apart as against 64 in. in freight car service, considering that the wheels are approximately 33 in. diameter, as against 36 in. to 40 in. on the motor truck and that the freight car is operating on a perfectly smooth road bed, whereas the automobile is subjected to direct violent blows on the tires due to rough roads but suffers very much more from the side blows delivered at the rim of the wheel when swaying back and forth in deep ruts over country roads, and always having in mind that the designer's chief aim in motor truck axle design is to take care of these tremendous reactions from side skidding, curb work, etc., it is difficult to appreciate the reasons for the automobile truck designer following the full-floating construction, where the centers on which the reactions are taken are so very close together, contrasting so widely with the semi-floating design—in fact, the difference in these designs is so radical, that it is hard to conceive of both of them being on right principles. Even forgetting principles for the moment, there is such a weight of precedent in favor of the semi-floating, that the writer can only come to the conclusion that the full-floating is only used on account of the accessibility of the driveshafts. If the full-floating construction had been adopted by railroad engineers for the same reasons, people who knew these facts would have a very creepy feeling when taking any long journey by rail.

We prophesy before very long that advertising men in the automobile field will not boost the full-floating axle on account of its accessibility, when driveshaft failures take place. It is infinitely better to put a driveshaft in there that will not break. This is the least that one can expect with our present knowledge of alloy steels and their proper heat treatment.

Full-Floating Impossible on Locomotive

Imagine locomotive designers starting out to design a full-floating axle for the locomotive itself, particularly on the main drivers. It would be considered by railroad engineers a practical impossibility. The bearings would be so large that there would be no spoke left in order to take care of the reactions when rounding curves, always having in mind that a choice of bearings is made from the side pressures at the rim of the wheel and not the straight static loads on the axle.

The illustration as shown in Fig. 1 is quite well known but clearly outlines the relative merits of each. The one with outstretched arms representing locomotive or semi-floating axle construction while the other represents full-floating or wagon practice.

Taking for granted that the locomotive, passenger and freight cars are all of the semi-floating or fixed hub construction and that the full-floating is horse-drawn practice (so far as its capacity for taking curves is concerned)

should the motor truck builder follow locomotive practice or revert to horse-drawn design? This is no reflection on the carriage axle—the present form of axle serves its purpose well for horse-drawn work, but this design would never do for real heavy haulage where speed is a consideration.

Again, on locomotive design the unsprung weight is really not a consideration on account of the very slight spring deflection due to the excellent condition of the road bed, but where such large unsprung weights have to be used as in modern worm drive axles, it is very much more essential that the semi-floating axles be used on trucks than in locomotive practice, as one of the principal items in the maintenance cost of heavy motor trucks is the tires consumed.

One of the most wonderful designs in the pleasure car world, noted for its exceptional gasoline economy and big tire mileage, attributes some of its success very largely to the semi-floating axle, full-elliptic springs and the Hotchkiss drive, particular attention being paid to reduction of weight at the wheel hubs themselves, even carrying this out as far as the rim and dispensing with the conventional demountable rim in favor of the fixed one in order to save weight where it is most detrimental.

Motor truck users who have had experience or even know of the above machine will expect the same relative tire mileages from their trucks and will certainly demand the lightest possible weight at the wheels on any axle equipment, even going so far as to condemn heavy cast malleable brake shoes and their attendant two-point contact, necessitating much heavier flanged and reinforced brake drums than are required with the self-intensifying band type of brake.

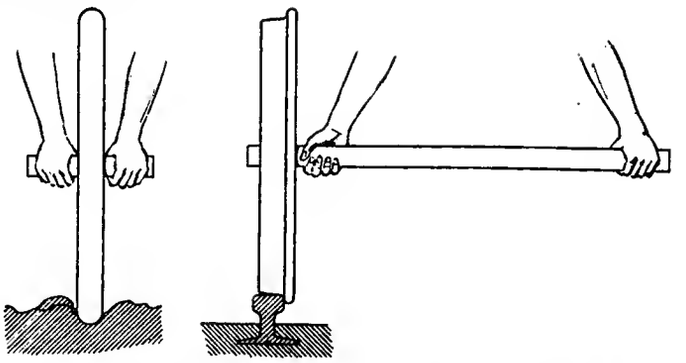

Fig. 1—Illustrating full and semi-floating axle arrangement

If all these considerations are being made in the pleasure car field, we prophesy that before long motor truck users will demand the same attention to details *for economy* of operation which has characterized the endeavor behind this design for the last nine years.

Solving Two-Cycle Problems

By Harmon J. Kline

THE recent articles appearing in the Forum of THE AUTOMOBILE seem to cover the pros and cons of the two-cylce motor situation pretty well. Some engineers are open to conviction while the majority seem to think the game isn't worth while.

The experience of most of these men appears to have been a matter of disappointment. My own experience was of about the same nature but still there is always a hope that luck will change. Theoretically the two-cylcle should begin to appear at this time since the performance of the multiple cylinder four-cycle motor may be had in the two-cycle type having only half as many cylinders and at a lower manufacturing cost. However, the hope seems a long way off if the opinions of the majority are to hold.

It is true that a motor using crankcase compression is troublesome, particularly with the low grade of fuel we are now getting. Oil leaks are also a bad feature and stuffing boxes a nuisance.

Probably a still greater disadvantage is the fact that a fresh charge from the crankcase must be forced into the cylinders at each cycle. I say "forced" because it must of necessity displace a sufficient quantity of dead gases in order that ignition may take place at all. However, this forcing process does not give good results in the ordinary type of two-cycle motor because the fresh charge always enters the lower end of the cylinders and part of it makes a bee-line for the exhaust ports. If the ports are carried around the cylinder walls far enough to allow a free escape of the dead gases, a greater proportion of the fresh charge is wasted for the sake of speed. So it is that in practice there seems to be a strata of inert gas at the top of the cylinder and one of fresh mixture at the lower end. The combination must be rich enough to allow ignition to take place, and it is obvious that trouble will ensue. At light loads the motor will four-cycle, back-fire or stop. At full loads the operation is better, but more fuel is wasted by passing out at the exhaust ports, due to the forcing process.

Is it any wonder that with raw fuel in the crankcase and a contaminated mixture in the combustion chamber, that the majority of engineers have hopelessly lost faith in any two-cycle type of motor?

If the cylinder action could be reversed properly without too much complication, I think the past reputation of the two-cycle motor would be better.

By forcing air into the upper end of the combustion chamber to scavenge the cylinder before forcing the fresh charge in, the motor will two-cycle under all conditions of load and speed. The motor may be flooded when using the overhead vaporizer so that dense clouds of smoke come out with the exhaust and yet it will two-cycle almost entirely.

When operating on gasoline with a carbureter I found out, under actual operating conditions, that back-firing would occur occasionally, due perhaps to a complete circuit of explosive mixture from the crankcase to the combustion chamber. However, the motor would not stall because the back-firing always occurred in one crankcase and the other would immediately fill the storage chamber with a fresh charge.

The motor was never known to back-fire when using the overhead vaporizer except when a valve cage in the piston came loose or a valve broke below the head.

As for starting on gasoline with a carbureter to the crankcase, starting is a bit difficult by hand but if a belt is run to the flywheel to give the same speed as an electric starter would give very little trouble was experienced. Perhaps the ordinary two-cylcle would start better now, even on our low grade gasolines with a starter but the two-cycle died before this day of extensive equipment.

Need for Cool Crankcase

As to running with hot crankcases. I think it would not be feasible to do so, particularly as means of lubrication cannot be so advantageously used in the two-cycle as the four and yet the four-cycle operates at too high a temperature to give absolutely reliable operation in the hands of the public. If some sort of cooling could be used to keep the bearings and oil at a comparatively low temperature it would be a good thing, especially with the two-cycle motor where a copious supply of oil is not advisable.

There is another point in favor of the two-cycle motor as applied to air cooling. That is the positively operated valve action. It is unnecessary to compensate for the difference in expansion of the cylinders and the push rods, valve tappets or valve stems as in the four-cycle motor.

The History of the Pneumatic Tire—16

Early Use of Pneumatic Tires on Automobiles and Other Vehicles—Motorcycles First Motor Vehicles To Use Them—Michelin's First Automobile Pneumatics

The History of the American Automobile Industry—43

By David Beecroft

PROBABLY suggested by The Lovell-Diamond advertisement of May, 1897, containing a cut showing letters on the tire of the wheel, an article appeared in one of the bicycle publications about this time, describing an advertising device, consisting of a bicycle wheel having the legend to be printed on the road formed in raised type on the tire tread. In April, 1898, the National Herringbone tire was advertised.

First Use on Automobiles

The first use on automobiles seems to have been the corrugated tread tires used on the Mark 111 Columbia in 1898. This vehicle was introduced in 1897 and may have used corrugated tires earlier than the date above mentioned.

For Horse-Drawn Vehicles

The increasing use of pneumatic tires very naturally suggested their application to other road vehicles than bicycles, and the application to sulkies by Elliott, Bidwell and Sercombe-Bolte has been mentioned. In the Winter of 1891-1892 A. H. Overman of the Victor Co. had his buggy fitted with ball bearings and the Victor arch or cushion tire which he was strongly advocating, and with which he was trying to stem the tide of favor sweeping toward the pneumatic. In the Spring of 1892, Bidwell fitted pneumatic tires to two Stivers runabouts and drove one of these himself about the city. This use seems to be the first use of pneumatic tires on horse-drawn vehicles in this country, if we omit the reported use of a carriage with Thompson tires in 1847.

First Use on Motorcycles

Since the motor vehicle developed so naturally from the bicycle which required better machine shops than did the carriage, it is to the motorcycles that we must look to see the first use of the pneumatic tires or motor vehicles. Most of these earlier motor attempts, however, were made on cushion or solid tires because the maker felt that the bicycle tires were not able to carry the heavier load. The first use on motorcycles seems to have been that of Pennington about 1894, who employed small wheels and having a very slow-running motor, with no flywheel, used quite large tires specially built for him to absorb as many as possible of the jolts. Pennington claimed earlier date than this, and this date is believed to be conservative. The *Blacksmith and Wheelwright* of September, 1894, describes an English four-wheeled car propelled by electricity having ball bearings, 24-in. wheels and pneumatic tires. Whether this use was earlier than Pennington's, is not known, but, being a four-wheeler, it more nearly approached automobile construction.

Early Use of Single-Tube Pneumatics

The first use of pneumatic tires on an automobile of accepted gage, wheel size and general road vehicle characteristics, as distinguished from cycle construction, seems to have been on the Duryea Chicago winner, which was fitted with single-tube pneumatics, 44 by 2 in. front, and 48 by 2 rear, about May, 1895. These single tubes were duplicates of others used by the Pope company on its horse-drawn delivery truck, carrying bicycles to the pay-station for some months before. Early in the same year, a New York hospital ambulance, weighing 1850 lb., had been fitted with Dunlop 3-in. tires; so these pneumatics were not chosen by Duryea until such tires had been proved capable of performing the work required.

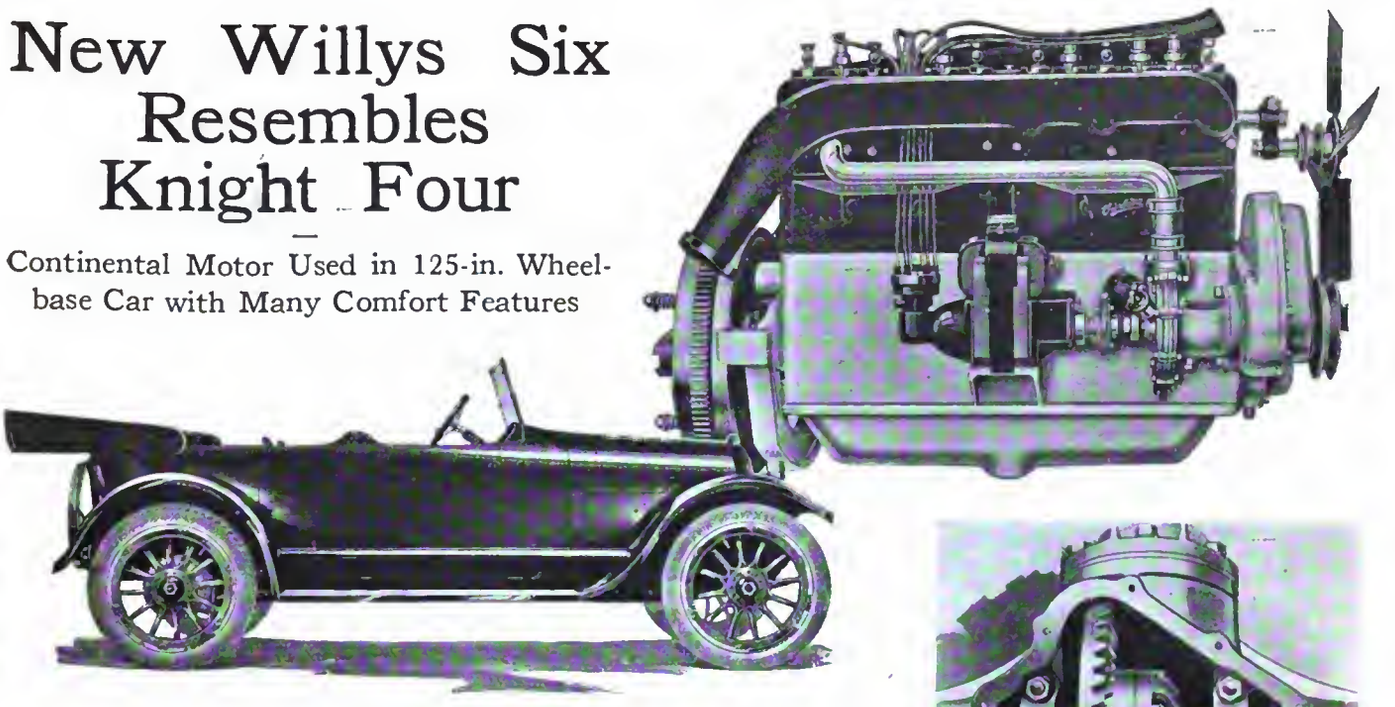
In an Early Contest

Morris & Salon built for the Chicago contest a skeleton bat which was fitted with wire wheels and pneumatic tires and is probably the second use of these tires in the United States. It is, however, hardly fair to compare this skeleton with a full-fledged automobile, for it was built for contest purposes only and was a cycle rather than an automobile.

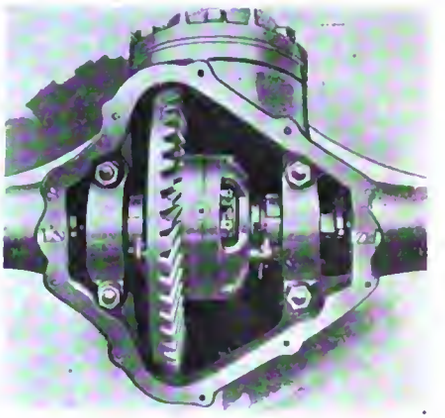
In the Summer or early Fall of 1895, Michelin, the well-known French tire maker, began to supply pneumatics for automobile use. It seems certain, therefore, that America led the world in the use of pneumatic tires, both on motorcycles and automobiles. More than a dozen Duryea cars were made during the winter of 1895-1896 and fitted with 34 by 2½ and 38 by 2½ single tube tires. The sale of several of these vehicles in June, 1896, and later constituted the first commercial transactions in pneumatic-tire automobiles.

New Willys Six Resembles Knight Four

Continental Motor Used in 125-in. Wheelbase Car with Many Comfort Features



Touring car and power plant on Willys 88 six chassis



Final drive in Willys axle, showing differential

WITH the exception of a longer hood, the new Willys seven-passenger 88-Six at $1,325 is identical in appearance with the Willys-Knight four recently described. Cantilever springs have been substituted for three-quarter elliptics, battery ignition made by Connecticut has taken the place of the magneto, the gearbox used on the 1916 Willys-Knight has been adopted, and the gasoline tank has been moved to the rear from under the seat, the change bringing with it the installation of a Stewart vacuum system. Continental motor, Auto-Lite starting and lighting, and the Tillotson carbureter are the same as heretofore.

Comfort and beauty are the features of the new car. The lines are unbroken from front to rear. The radiator edges are rounded, and the radiator is slightly higher, the top edge of the body is rolled in, and there is a double cowl and a tilted windshield. All these details combine to give a very attractive car.

Dark Blue with Nickle Trim

The body is dark blue, with gray wheels. Metal fittings are nickel and polished aluminum, and fenders and trimmings are black enameled.

The car is comfortable. The upholstery is unusually soft, due to the use of smaller springs, and because each one is in a canvas casing, which acts as an air chamber, giving a pneumatic-cushion effect. The body is roomier. There is plenty of knee room when the auxiliary seats are up. Cantilever springs, 48 x 2½ in., make this the easiest riding Overland, since it also has the longest wheelbase, 125 in. Larger tires than usual, 35 x 4½, contribute to the easy riding. The springs have been attached to the axle in such a way that the tendency is for the axle to roll backward slightly, thus reducing the force of the shocks.

The new motor will throttle down as low as 4 m.p.h. on high gear, and still run smoothly, and will pick up quickly from this speed without any difficulty. The ability of the car may be judged from the fact that the motor is rated at 45 hp., has a gear ratio of 4 to 1, and weighs 3515 lb. with all tanks full and a spare non-skid tire and rim.

The bore and stroke are 3½ x 5¼, giving an S. A. E. rating of 29.14 hp. and a piston displacement of 303 cu. in.

The motor is a standard Continental mode, with L-head cylinders cast in a block and mounted on a two-piece aluminum crank case, the lower part serving as an oil reservoir and the upper carrying the three-bearing crankshaft.

Accessibility is fostered by placing the ignition distributer and the generator and the water pump in a straight line on the right side. These units do not interfere with reaching the valves. Each is mounted on a bracket on the motor, and may be removed without disturbing the other.

This leaves the left side of the motor clear for the installation of the steering gear and the starting motor, access to both being easy. The oil-filler opening is at the front, on this side, and the oil gage is plainly visible from its position at the center near the bottom of the crankcase.

Electrical equipment consists of an Auto-Lite two-unit, six-volt system, with head, tail, and dash lamp, and headlight dimmers, as well as an ammeter.

The starting motor is mounted high in order to keep it away from dust and dirt, as well as to make it accessible, drive being by Bendix pinion, which meshes with teeth in the flywheel.

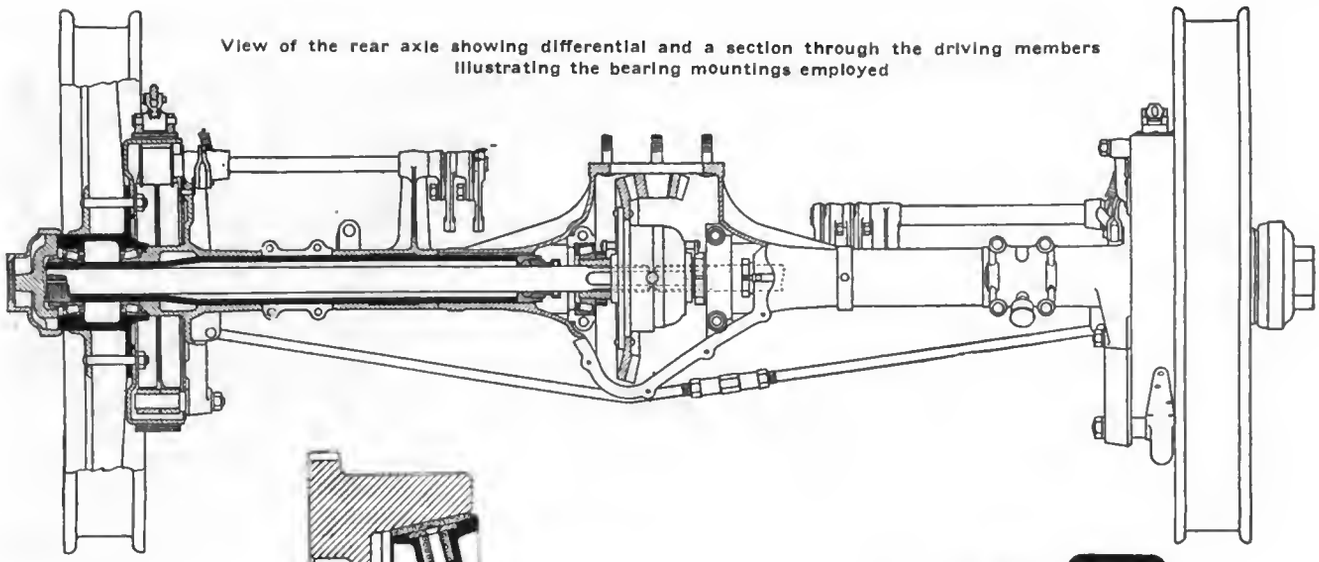
Back pressure is minimized by the fitting of a double exhaust pipe, there being a passage from the three front cylinders and another from the three rear ones.

Lubrication is a combination of force and splash feed, a plunger pump operated from the camshaft sending oil under high pressure to the main crankshaft bearings, camshaft bearings and the timing gears. Troughs catch the overflow and dippers on the connecting-rod caps distribute spray to all parts of the motor.

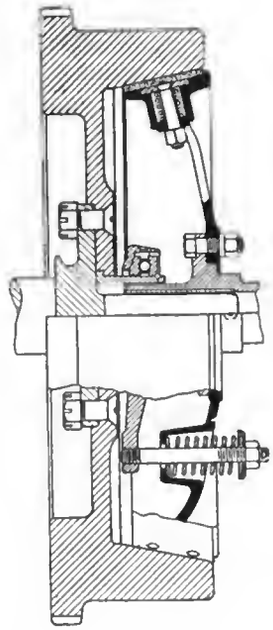
Leather Faced Cone Clutch

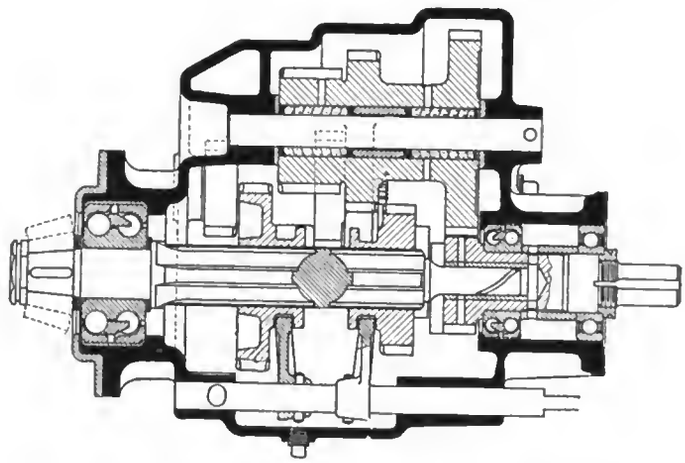
The clutch is a cone with a leather facing, and spring-actuated plungers which are equally spaced give smooth engagement by pressing out on the face. The clutch spider is held in engagement by three comparatively light springs

View of the rear axle showing differential and a section through the driving members illustrating the bearing mountings employed



Section through the leather faced cone clutch showing spring engaging members beneath the leather to give a gradual application and to ease starting shock





Three-speed gearbox used on the Willys model 88 six-cylinder car

placed near the rim, and gear shifting is facilitated by a clutch brake.

The gearbox is mounted on the rear axle, and torque and driving strains are taken by a torque tube which terminates in yoke, which is pinned to a cross member of the frame. The gearbox gives three speeds forward and reverse. The gears are double-treated nickel steel of the stub-tooth type. The main shaft is mounted on annular ball bearings and the countershaft is stationary, but the countershaft gears rotating on it have Hyatt rollers placed between them and the shaft.

The rear axle is a full-floating type with a spiral-gear drive, and Timken adjustable, taper roller bearings throughout.

Double Sets of Brakes on Drums

Service and emergency brakes are internal and external, acting on the same pair of drums, the former contracting and the latter expanding, the respective dimensions being 14⅝ x 2¼ and 14 x 2¼. Both are quickly adjustable.

The front axle is an I-beam drop forging, produced in one heat without welding, and the wheels have adjustable, taper roller bearings.

The steering gear is a worm and full-gear type of hardened steel. It is provided with ball-thrust adjustable bearings.

The doors are particularly easy to open, due to the use of a new handle, which is pulled in the direction to close the door. This movement is easier than that required to unlock the ordinary door, especially when the door is stuck. For the sake of cleanliness and safety, rubber pads with ridges on them have been placed on the running-boards under each of the four doors. They not only act as mud scrapers, but also give a firm foothold.

Light Pressure Releases Clutch

A very light pressure is required to disengage the clutch, merely the rocking of the foot on the heel being sufficient to depress the pedal. Horn button and ignition and lighting switches are placed in a box on the steering post, where they are easy to reach. Gear shift and emergency-brake levers may be operated without leaning forward. The two large pedals are adjustable as to length.

The cowl-board equipment is complete, including a Warner speedometer with ½-in. figures on the speed-indicating cylinder and ¼-in. figures on the 100,000-mile indicator and on the 100-mile-trip register. The latter may readily be set back by turning a small knob at the right. The oil gage registers up to 10 lb., and the ammeter has a range of 15-0-15 amp. A Boyce Motor-Meter relieves the driver of worry as to the condition of the cooling system.

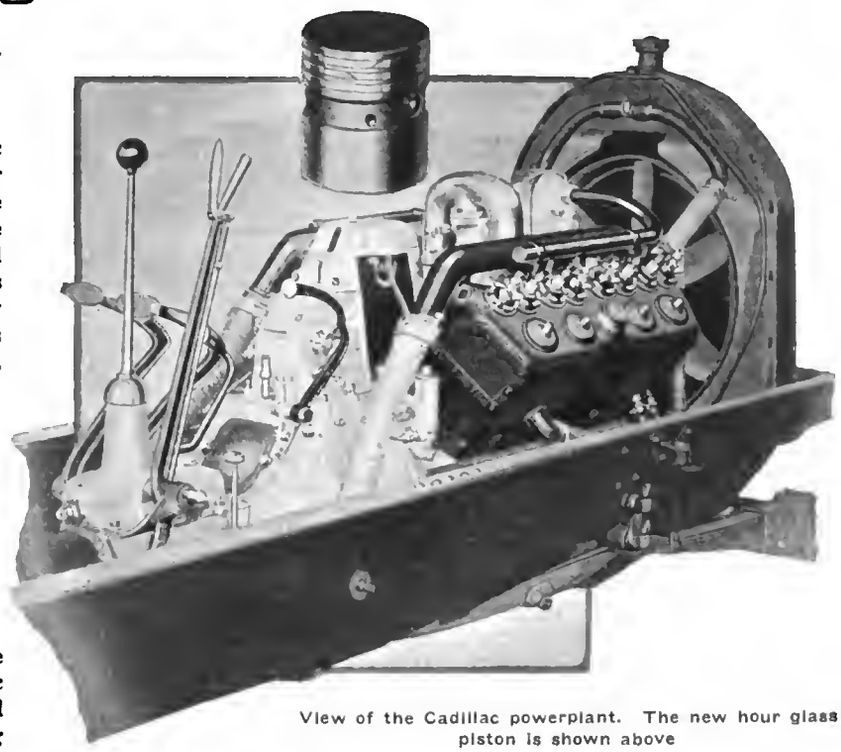
The body lines on this car are up-to-date and carry out a pleasing adaptation of the modern idea of streamline or moulded form. As will be noted there is little or no break at any point on the body as the cowl line joins the line of the body edge with an easy sweep. The rear of the body also rounds off in a graceful manner so that the lines of the car are distinctly long and low. When the top is down this lowness is accentuated, giving a very graceful form with plenty of room in the interior.

Cadillac 55 Longer and More Luxurious

Mechanical Changes of a Detailed Nature Giving Accessibility

FOR the third successive year the Cadillac Motor Car Co. ushers in its eight-cylinder car with no marked changes. There are some differences in the new Type 55 over the Type 53 which it succeeds, but these should be regarded more as refinements. Prices of the open models remain unchanged at $2,080; but the closed-body models, all built upon exactly the same chassis but of 132-in. wheelbase, are raised somewhat, due to the added cost of their manufacture.

Perhaps the most important difference in the new Cadillac is the lengthening of the wheelbase 3 in. to 125 in., a change which adds to the appearance of the car and increases its riding qualities at the same time. The rear of the body has been lowered somewhat, due to a little alteration in the bottom of the body in order to give it more clearance over the axle and also to some revamping of the top body line. These new features, together with the using of crowned fenders, make the new Cadillac the most beautiful car the concern has yet offered the public. As an added touch, there is a molding around the top of the body in the seven-passenger type, which sets it off in admirable shape.



View of the Cadillac powerplant. The new hour glass piston is shown above

Mechanically the changes are very few indeed. The motor has been fitted with new and lighter pistons which are somewhat on the hour-glass order in that the center is of smaller diameter than the top and bottom, thus reducing the bearing surface within the cylinders. There are a number of return oil holes drilled around this center portion to return any surplus lubricant to the crankcase, and, besides this, the wrist-pins have been enlarged somewhat as an added factor of strength. Last year's car had straight pistons. It is stated that the redesigning of the pistons and the slight refining of the rod assembly have resulted in the reduction of 1 lb. per rod and piston assembly, this meaning the two pistons, connecting-rods and bushing for any two opposite cylinders. This makes a net reduction of 4 lb. per motor due to the new piston design, etc.

Valves More Accessible

The valve alley between the blocks of cylinders has been made more accessible by redesigning the exhaust manifolds so that each is 1⅛ in. closer to its block of cylinders, a gain of 2¼ in. between these manifolds.

Due to the lengthening of the wheelbase the frame has been strengthened principally by making the side members 8 in. deep in the channel, an increase of 2 in. as compared with the previous model. This refers to the maximum frame depth, of course, there being the usual taper. A new feature in the frame also is the use of tubular cross-members at front and rear in place of the more generally used pieces of square or rectangular section. These, together with the deeper channel, make a more rigid frame that ought to be proof against any weaving that might be expected under severe road conditions. These tubular cross-pieces are not only stronger, but they are lighter than members of a different shape would be.

Another slight difference, which is nevertheless important in its effect, is the shifting of the torque arm from the left side of the propeller shaft to the right side, this being done to better absorb the torque of the motor, which turns from left to right. In the axle the mounting of the drive pinion shaft has been improved by placing both bearings ahead of the pinion itself instead of having one bearing either side of it, as in previous designs. This takes care of the thrust to best advantage.

These are all of the differences over the previous car, with the exception of several refinements that add to the convenience and comfort of the motorist as well as to the appearance. The tail lamp, for instance, has been redesigned so as to throw light upon the gasoline gage, making a very convenient detail at night. A splash shield now runs out horizontally at the front of the radiator and between the front ends of the frame, this giving better protection to the radiator than did the slanting guard formerly used.

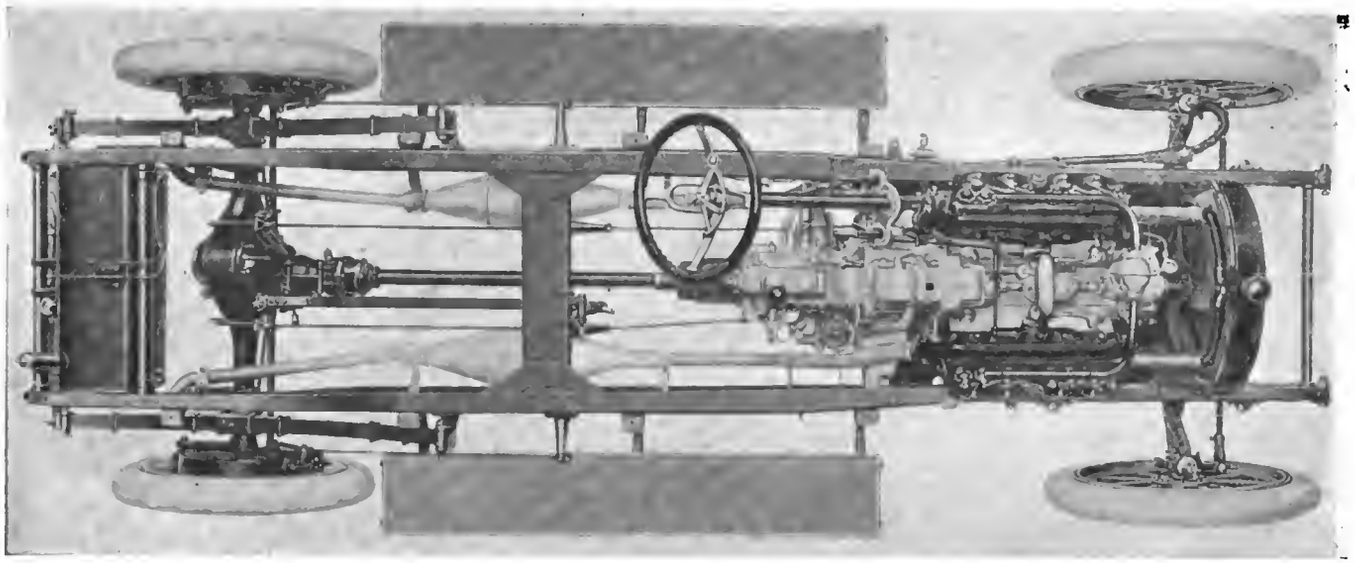
There has been a big upholstery change, adding materially to the comfort of the car. A new form of upholstery spring is used that is unusually soft, though it stands up well and will not settle. The leather is of dull grained variety instead of having a glazed finish, and in addition it is plaited instead of being tufted, undoubtedly adding to the appearance and comfort.

Head lamps of a new shape have been added, these having just a suggestion of the shape of the Cadillac coat of arms as it appears on the radiator and adding to the car's general good looks.

Gabriel snubbers swell the list of standard equipment, and are fitted both front and rear. A deep blue has been selected as the body color this year, taking the place of the dark green that was used on last season's cars. The color change, however, does not apply to the closed-body types; they still have a dark green paint.

Having summarized all of the important changes in the Type 55, it might be well to review the salient mechanical features of Cadillac construction for the benefit of those who are not familiar with them.

Since the Cadillac eight was first announced in 1914 there has been no alteration of the bore and stroke or of the motor



Plan view of the Cadillac model 55 chassis showing the accessible V powerplant and layout of the drive and torque members

basically. Cylinders have a diameter of 3⅛ in. and the stroke is 5⅛ in., giving a displacement of 314 cu. in. and a horsepower rating by the accepted formula of 31.25. This is nominal, for the motor will do well over 70 hp. on the block. In its general scheme the cylinders are in two blocks at 90 deg. and cast integral with the water jackets, heads and intake manifolds, making a simple construction. The aluminum alloy crankcase has the two blocks bolted to it in the usual fashion, and it carries the camshaft in its upper part, the crankshaft directly below the camshaft, and the oil reservoir at the bottom. A third shaft is placed vertically above the camshaft, this driving the Delco generator, ignition distributor and fan, and running in the alley between the cylinders. Actuation of the camshaft and generator shaft is by silent chains at the front, which are completely housed; and at the rear of the crankcase is the gearset, the bell-housing of which serves to complete the inclosure.

No Change in Principle

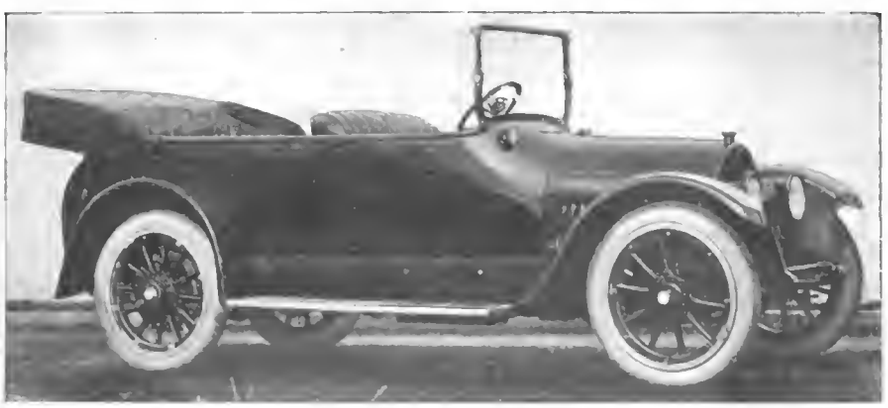
As the eight-cylinder type of engine is now known to the majority of persons, it need be said only briefly that the crankshaft is of the same form as used in a four-cylinder motor, only each throw bearing carries two opposite connecting-rod big ends instead of one. In the Cadillac adaptation the method of attachment of these two mating rods to the one bearing is by forming one rod with a yoked end and the opposite rod end of such width that it fits between the arms of the yoke. Two caps are, of course, required for the yoked end, one for each arm of the yoke; and in order to afford a proper bearing surface for each rod end the big-end rod is pinned to the outer ends of the bushing, while the other rod fits to the bushing within the yoke and is free to turn. Thus the bearing for the yoke rod is the inner surface of the bushing against the shaft, whereas that of the outer rod is the outside surface of the bushing.

Valves in the Cadillac engine are actuated by only eight cams, each cam operating two opposite intakes or two opposite exhaust valves, as the case may be. The cam assembly is on the under side of a plate which bolts to the top of the crankcase between the cylinder blocks, and pivoted to this plate are sixteen rockers (one for each valve), these being interposed between the ends of the push-rods and the cams so that the lift will be straight upward along the valve instead of having a side thrust, as would be the case if the cam worked directly against the end of the valve rod.

Force-feed lubrication remains practically unchanged in the new model. A gear pump positioned at the front of the motor and driven from the crankshaft draws on the supply in the oil reservoir at the bottom and forces it through a reservoir pipe running along the inside of the crankcase, from which there are outlets to each of the main bearings.

Thermostatic control of the water temperature is still used, there being interposed in each water pump line a thermostat which automatically closes the supply of water from the radiator when the temperature gets below a certain level, causing the jacket water to circulate and recirculate through the cylinders until such time as the water temperature mounts to the height at which the thermostatic valve is opened and the whole supply of water admitted, permitting the circulation of the water as in any other motor. Incidentally, each cylinder block has its own centrifugal pump, driven off the end of a transverse shaft below the crankshaft, to which it connects by spiral gears.

Some of the other specifications include a multiple dry-plate clutch having fifteen carbon steel plates 7¾ in. in diameter; floating rear axle having spiral-bevel driving gears and a pressed-steel housing; tubular open propeller shaft with universal joint at either end; platform rear-spring suspension that has long been a Cadillac feature; 20-gal. gasoline tank with fuel fed to the carbureter by pressure; power tire pump attached to the side of the gearcase and operating through the gears. The tire equipment consists of 36 by 4½ smooth treads in front and non-skids in rear.



Cadillac 55 touring car which has been rendered more comfortable and lengthened 3 in.

ACCESSORIES

Forbes Extension for Fords

THE Forbes extension renders the Ford chassis 36 in. longer. The change is made by removing the body, rear mudguards, splash plates, running boards, gasoline tank, muffler and exhaust pipe and cutting both side members of the frame through at the middle of the car with a hacksaw. A channel is then hot-riveted and swedged into the opened section, thus lengthening the frame. A cross-plate of cast steel is arranged between the lengthwise members of the extended section to take the thrust of the driveshaft. Each side of the frame is trussed throughout its length with steel rods secured to steel brackets at the ends of the frame. An intermediate driving shaft is furnished, together with brake rod extensions, longer running boards and splash plates and all other parts required in making the installation. The capacity of the truck is 1500 to 1800 lb. Price, packed for shipment, $100; installed, $135.—Walter J. Forbes, 243 Columbus Avenue, Boston, Mass.

Hartman Automatic Switch

When the switch is used fuses are not required, according to the maker, for an automatic circuit-breaker is incorporated in the switch and is said to instantly open the circuit when a ground occurs, and positively indicates the fact by throwing out a small button below the switch key. To close the circuit again it is only necessary to push the button in, and if it remains in position it shows that normal conditions have been restored. The switch key may be removed with the lights burning, so that they cannot be tampered with in the absence of the driver. A similar type of switch is made for the ignition circuit, thus preventing the draining of the battery in case the switch should be turned on while the motor is stopped.—Hartman Electrical Mfg. Co., Mansfield, Ohio.

Faw Wiring for Fords

Several improvements have been made in the Faw wiring sets designed for Ford cars. The terminals, which were formerly soldered on at the end of the primary wires, have been displaced by self-made terminals, which are produced by looping the end of the copper conductor and soldering it. Thus a solid terminal is made integral with the wire itself. A copper ferrule protects the end of the insulation at this point. Another improvement is the elimination of the rubber nipples at the end of the flexible metal tubing, a metal ferrule which screws in place being used instead. The primary wires are of different colors so that they may be easily traced. The outfit consists of four high-tension ignition cables cut to the right length and provided with soldered terminals and four primary wires. Price, $1.—J. H. Faw, Inc., 41 Warren Street, New York, N. Y.

Hartman automatic switch

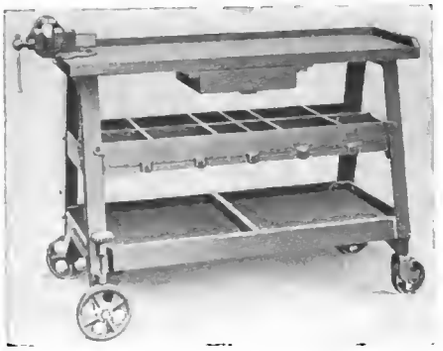
Howe searchlight

Howe Searchlight

The feature of this parabolic light, which is designed for mounting on the windshield, is the universal bracket, which has coil springs to provide a constant tension on the joints and thus holds the lamp firmly in place in any position. These springs, however, do not interfere with the ready movement of the lamp. The wiring is inclosed in the hollow bracket. Prices, $7.50; with rear-view mirror, $9.—Howe Mfg. Co., 61 East Twenty-fourth Street, Chicago, Ill.

Manley Portable Bench

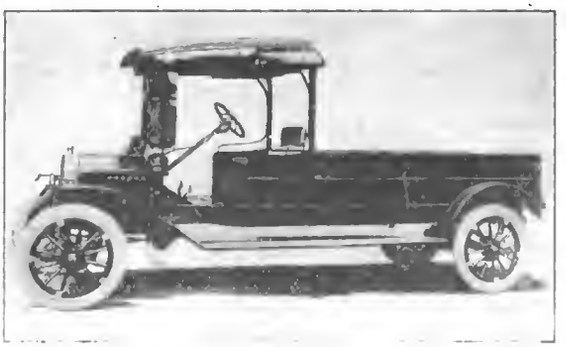
A floating machine shop is what the maker calls this bench. It is mounted on wheels on casters. The top is 12 by 44 in. and is equipped with a vise at one end as an extra. There is a drawer below the top of the table, and underneath are two shelves, the upper one having several compartments for parts of various sizes and the lower for heavier parts and tools. It should prove valuable in the repair shop, for it may be used right at the car, thus saving many steps. The construction is cast iron and steel throughout except for the top of the bench, which is wood.—United Engine & Mfg. Co., Hanover, Pa.



Manley floating machine shop

Economy Piston Ring

Economy piston rings differ from many in general use by not having pins to secure them in position. The illustration shows the method of joining the ends of the rings, with a tongue-and-groove device. They are concentric. In theory a concentric ring is said to insure equal bearing on the walls of the cylinder and consequently an even wear on the rings. This, and the absence of pins and loose parts, promote full compression, as the



Above—Forbes Ford extension. Right—Faw wiring

Anchor weatherproof top for Fords

ends of the rings can be sealed so tightly as to prevent any leakage whatever at the joint. The rings range in prices from 90 cents for 2½ to 3½ in. diameter, to $2.25 for 6 to 6½-in. diameter.—American Piston Ring Co., Minneapolis, Minn.

Anchor Tops for Fords

These tops are designed to be quickly attached to Ford cars, so that a closed car may be had for cold weather use and an open car for warm weather. The frame is of wood and the sides and back are glass. The doors of the top and car doors open together being operated by a single patented locking device. The interior of the top is upholstered and the windows can be lowered or may be removed and curtains substituted. Price, sedan $57.50, coupe $47.50.—Anchor Buggy Co., Cincinnati, Ohio.

Badger Tire Holder

This tire carrier is designed especially for the 490 Chevrolet, which is not regularly equipped. It is made to carry a single tire at the rear, and is suitable for a plain tire or one mounted on a wire wheel. It is attached to the rear body sill by through bolts. Price, per set, complete with straps, $3.25.

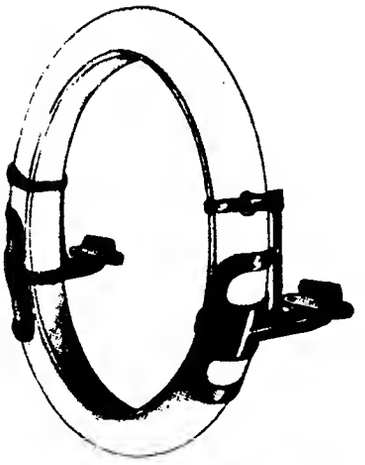
A new rear tire holder has been designed for Fords, consisting of a single drop arm which is clamped to the rear spring and from which extend two arms to support the tire at the side and also a central arm which carries the tail light and the license plate. Complete, without lock, $3.25, and with lock, $3.75.—Auto Parts Mfg. Co., Milwaukee, Wis.

Mud Cover for Ford Cars

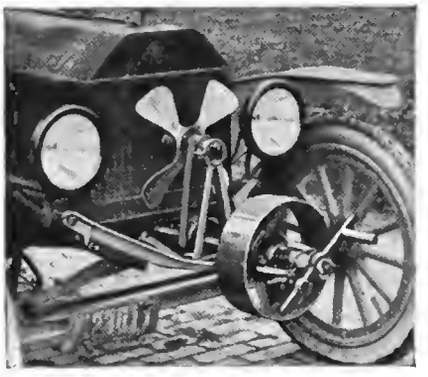
This is a new mud cover which slips on over the fenders, body and doors, and may be put on or taken off in 5 min. Waterproof material is used. Fasteners of the ordinary kind found on gloves are used. The covering protects the finish of the car against mud and water in wet weather.—Edward McClintock, Minneapolis, Minn.

Apco Spring Leaf Lubricator

These lubricators consist of a pair of semi-steel plates with oil reservoirs and felt inserts, as illustrated. When in position the felt rests against the spring, keeping it lubricated without any attention except occasional renewal of the oil supply. The devices can be installed in 2 min. with a screwdriver. They are finished in black enamel and are tapped to take oil cups. The large size is 2 in. between bolts and the small 1½ in. Ford cars require four sets, two small and two large, while cars with full elliptic springs will need sixteen sets; semi-elliptic need eight; three-quarter with semi-elliptic front need ten, as do cars with platform springs. The lubricators sell for 30 cents per pair.—Auto Parts Co., Providence, R. I.



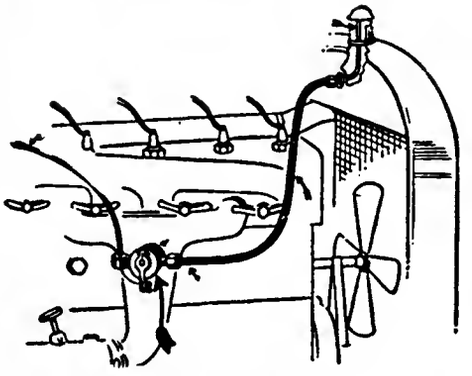
Badger tire holder



Autopower attachment for Fords

Autopower Attachment

Power for driving stationary farm machinery may be obtained from a Ford by the use of this device, which consists of a pulley mounted in front of the radiator and which is driven from the crankshaft. A belt-driven fan supplies extra cooling. It may be attached without any drilling, the only tool required being the wrench. It is capable of supplying 10 hp. continuously, it is said.—Autopower Co., 965 Woodward Avenue, Detroit, Mich.



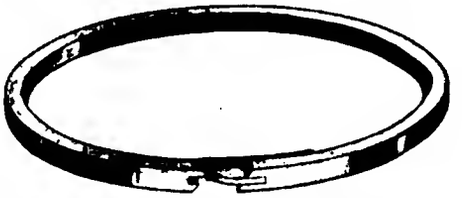
Vapo Humidifier supplies moisture to the carbureter

Vapo Humidifier

This device supplies warm, moist vapor to the manifold, the exact amount being controlled from the dash. It consists of a valve at the manifold from which runs a pipe to the filler spout of the radiator, from which point the vapor is procured. It is said to provide a better mixture and, consequently, to improve the power and smoothness of operation of the engine. Price, $5.—Auto Gas Saver Co., 29 South La Salle Street, Chicago, Ill.

Petry Cut-out

This cut-out is a damper type, one position of the damper deflecting the exhaust gases down into the open and the other position allowing them to pass through to the muffler. The valve may be readily removed for cleaning, and the tension of the closing spring may be varied to suit the requirements. Prices: 1¼ to 1¾ in., $3; 1⅞ to 2½ in., $3.50; 2⅝ to 3 in., $4.—N. A. Petry Co., Inc., Philadelphia, Pa.



Economy piston ring. Note the absence of pins

Federal Gasoline Report

NO one seems to be able to put his finger directly on the cause of the country-wide reductions in gasoline price That it is due to the investigation of the Federal Trade Commission is vigorously denied on all sides, but it seems quite a coincidence that the reduction comes just as the report is due. There has also been talk that the price has been forced down to allow the Standard Oil companies to buy up existing stores at bargain prices, but here again there is a cheerful indefiniteness about the reports.

Gasoline prices run in waves, and each time there is a rise or fall a host of explanations is always ready. The oil magnates cite the law of supply and demand, and yet a close investigation always seems to indicate that the ratio of demand has not varied much. It is to be hoped that the gasoline report from the Federal Trade Commission, which is just about due, will clear up a large part of this mystery.

Some of the oil men state, and very possibly with reason, that as soon as the oil demand rises to a high pitch all the little producers and independents all through the oil-bearing country immediately dig wells, and consequently the production goes up. In other words, it is a question of the production varying to meet the demand rather than a case of the demand being varied to meet the production. All over the country there are numerous wells of small output when taken singly or in small groups, but when the production of these wells is combined it makes a total that can very well swing the tide over toward a lower price scale. There is no doubt, also, that the automobilist is content with a lower-grade fuel now than he would have been a few years ago, because cars are being built that will burn the heavier grades satisfactorily.

Ford Service

FORD'S epoch-making announcement of an entirely new way of marketing automobiles, following closely on the heels of a deep slice into the price list, is so fraught with possibilities that it is only after the atmosphere begins to clear that the deeper significances of the plan become visible. Here and there the question is now being asked if the cut in price is not being made to some extent at the expense of a cut in service.

No doubt the new plan of merchandising will be more economical from every view point. If money is to be saved on service, that money will be left in the pockets of purchaser as well as in the coffers of the Ford company. When a man buys a plow or a lawn mower he does not ask the dealer searching questions regarding service for the implements. He knows that, having been built by a large factory that expects to continue in business, the service feature goes without saying. He knows that through any dealer handling the product of the large manufacturing organization he can buy or order parts.

The low-priced car is as much of a utility device as the lawn mower and the plow. Its use is just as widespread and general. Therefore, it is but natural that, since the marketing method of the car will follow out the plan found desirable in other lines of utility hardware, the service method will do likewise.

Stronger Financing

THE era of prosperity which has swept through the automobile industry, and which is still continuing its sweep, has brought about a result that will be appreciated should a period of depression ever ensue. It has always been said that many of the larger automobile manufacturing companies did not have sufficient reserve. This condition, if it ever in reality existed, is past. Almost each week there is some increase in capitalization among representative concerns in the industry to enable policies of expansion to be carried out.

In addition to expansion, most of the companies are building up a reserve that will prove a tower of strength should a period of need ever arise. Some of the increases made this year are a striking commentary on the vastness of the resources of the country and the tremendous buying power that has still been practically untapped. Larger schedules of production are being announced on every side for the new fiscal year. In spite of the quick growth, a soundness and firmness is being manifested which puts the industry in the best possible light before the banking interests of the country.

Judge Investigates Headlight Device

Makes First Bonafide Decision in Mass., Stating Warner Lenz Complies with Law

BOSTON, MASS., Aug. 19—The first judicial decision on the headlight law where a judge went out for himself and made an inspection of a device was rendered in the Boston courts yesterday when Judge John Perrins, Jr., stated that the Warner lenz complied with the Massachusetts law.

The importance of the decision lies in the fact that a judge has really passed upon the matter after a demonstration. Heretofore the judges sat in court and heard policemen say a light dazzled even if it had a device on it, and the officer's word was accepted, and the motorist fined or his case filed. But no judge would take the trouble to investigate the claims of the motorists. They seemed to hedge on the question when attorneys tried to fight the cases.

The Highway Commission refused to approve any device because the devices were so made that improper focusing defeated the purposes of the inventor. When the case of the Warner Lenz came before Judge Perrins the attorneys laid much stress upon the fact that the judge should investigate the facts rather than rely upon the policeman's word. Judge Perrins said it seemed fair, and a trial was made one evening. The judge was convinced the Warner was not a lawbreaker.

In his decision he said: "The fact is that a certain space must be illuminated, according to the law, and a certain strength of light must be used for this purpose. When space 150 ft. away must be made light, the illuminating source must be accordingly brilliant. But I find this light not to be dazzling." In a former case with a Frecto device he discharged the defendant, but said that it may have been possible to break the law by improper focusing of the bulbs. If other judges follow Judge Perrins' lead and make investigations for themselves the police and the motorists will then know just where they are at. Police officials accompanied the judge on his trip in the Boston parkways while making his tests.

—

A. L. Westgard to Build Tires

YOUNGSTOWN, OHIO, Aug. 18—A. L. Westgard, well known in this country as an authority on good roads, is at the head of a new company which will build tires. He has formed the Westgard Tire & Rubber Co., with a capital of $1,500,000, and will locate a plant on a site of 4½ acres just northeast of Warren.

The concern has its building plans completed and is at present negotiating with contractors for the erection of the plant. Concerning the operations at the new plant, it is stated that 400 tires will be the daily production and 200 men will be employed at the start.

Mr. Westgard is president of the corporation. Other officers are: A. E. Gordon, vice-president and manager, and F. A. Vallbrecht, treasurer.

Mr. Westgard is well known in this section. For many months past he has been connected with the National Good Roads' Assn., and in the interests of the organization has made twelve trips across the continent.

—

Denmo Is New Truck

CLEVELAND, OHIO, Aug. 21—A new assembled truck to be called the Denmo has just been put on the market by the Denneen Motor Co., this city. The truck sells for $1,385 chassis, and is rated to carry 1¼ tons. It has a Splitdorf-Aplco lighting and starting system as stock equipment. The engine is a Wisconsin four, 3¾ by 5 in. and transmission is through a three-speed gearset to a Torbensen internal gear axle. There is a governor driven from the propeller shaft, so that it is the truck speed and not the engine speed which is controlled. Special pains have been taken with the thermo-syphon cooling system, the radiator, a Fedders, being mounted on a cushion base which gives it a more widely spread support than the usual spring brackets at the lower front corners.

Nine feet of loading space are provided, the wheelbase being 124 in., but it is stated that the truck will turn in 21 ft., as a very wide steering lock.

—

Pays Customer for Broken Parts

INDIANAPOLIS, IND., Aug. 21—A novel service policy has been started by the Fisher Automobile Co., local Reo dealer. This company has advertised that all parts broken in normal service within 1 year from delivery date will not only be replaced promptly free of charge for material and labor, but it will, in addition, pay to the customer an amount equal to the price of the new part as shown in the price list, as compensation for the annoyance and loss of time.

—

U. S. Advocates System

WASHINGTON, D. C., Aug. 21—The Federal Trade Commission which was formed to better trade conditions and relations has taken a deep interest in accounting systems and has issued two pamphlets covering the principles of accounting. One pamphlet is for manufacturers and the other for retailers. These do not advocate the use of any particular system, but urge greater attention.

Overland Adds $15,000,000 to Capital

$7,500,000 Has Been Sold and Remainder Is Being Underwritten

NEW YORK CITY, Aug. 23—The Willys-Overland Co., Toledo, has increased its capital from $22,500,000 to $37,500,000 by the sale of $15,000,000 of its common stock held in the treasury to J. S. Bache & Co., and C. D. Barney & Co.; $7,500,000 of this has already been sold and the remainder is being underwritten. The new stock will carry a 5 per cent stock dividend declared payable on April 2, 1917, to stockholders of record on March 15, 1917.

Common shareholders of the Overland company may subscribe at $44 a share to the new stock, two-thirds of a share of the new for each share held. There is also outstanding $15,000,000 of 7 per cent preferred, convertible into common stock.

The preferred shareholders, under the law, have no right to subscribe to any part of any new issue of common stock, but in view of the fact that the preferred stock is convertible into common stock, Mr. Willys has waived, in favor of the preferred shareholders, a sufficient amount of the stock to which he has the right to subscribe, to permit of an offering to the preferred stockholders of one share, par value $25, for each share of preferred stock outstanding.

The new common stock is worth about $2.50 a share less than the stock now outstanding, since the 10 per cent common stock dividend ordered on July 12 last is payable 5 per cent on Oct. 2 next and 5 per cent on April 2, 1917. As stated above, the new stock will not carry the 5 per cent payable in October.

After the receipt of the proceeds of the $15,000,000 of stock, the Willys-Overland Co. will have approximately $15,000,000 of cash and $30,000,000 of other strictly quick assets, with no liabilities other than strictly current monthly bills. The earnings of the corporation on a basis of the first 6 months of this year are approximately 40 per cent upon the par value of the common stock, including that proposed to be issued.

Proceeds from the new stock issue will be used to provide for the company's present requirements, for future growth, to insure prompt delivery of all orders, and to permit of increased disbursements from time to time in the way of dividends.

The company has an authorized issue of $50,000,000 of stock, that amount having been fixed upon, according to a statement issued by the bankers, in order to furnish adequate capitalization for the

growth of the business. Deliveries of cars for the first 6 months of this year were 94,477, being more than for the entire year 1915. The company is now approximately 25,000 cars behind in actual deliveries of cars sold.

Broken Marmon Seals Due to Road Contact

INDIANAPOLIS, IND., Aug. 8—The Nordyke & Marmon Co., this city, has made a statement in regard to the report of the Automobile Club of America on the examination of the Marmon car which established a record between New York City and San Francisco in 5 days, 18 hr. and 30 min. The club had placed seals and marks of identification on the car before its departure and on its return found certain of these broken. These seals that were missing, according to the Nordyke & Marmon Co., were so placed that they came in contact with the road, and were in this way either broken or torn away. The breaking or loss of these seals, under the circumstances, is not significant, being due entirely to an unfortunate choice of position and not for the purpose of making repairs.

The report shows the original wheels were missing. Inasmuch as wire wheels, standard equipment, were used, changes were made quickly by taking the wheels with the tires mounted completely off and substituting others with inflated tires.

King Making 2-Week Run

WASHINGTON, D. C., Aug. 19—An 8-cylinder King touring car is making an unofficial 2-weeks' non-stop run on the boulevard between this city and Baltimore. The start was made at noon, Aug. 12, from the plaza fronting the United States Capitol, and at the conclusion of the first 168 hours' run had a mileage of 3515 miles. The gasoline consumption has averaged 12.126 miles to the gallon. Ankeny and Ldutbecher are alternating as drivers. Edelen Bros., of this city, and J. Stewart Smith, of Baltimore, are promoting the run.

Pullen Will Captain Five Mercers

SANTA MONICA, CAL., Aug. 21—Eddie Pullen will captain a team of five Mercers in the Vanderbilt Cup and International Grand Prize races.

Sixteen-Valve Stutz Roadster Ready

Car Featured by Getaway and Silence—Remains Cool with Retarded Spark

INDIANAPOLIS, IND., Aug. 22—The Stutz Motor Car Co. announces a new speedster model in which will be installed a sixteen-valve, four-cylinder D-head motor. Experimental cars have been on the road since Stutz first introduced the sixteen-valve motor in racing cars, and rumors have been current for some time that the motor would eventually be marketed. The speedster model alone will have the new motor, the four- and six-passenger and roadster bulldogs continuing with the eight-valve motor as stated previously in THE AUTOMOBILE. A representative of THE AUTOMOBILE drove the car and the motor is as quiet if not more so than the eight-valve Stutz. Although twice as many valves are in operation, the second set seems to have been quieted to the minimum.

The car has a getaway rarely equaled in a four-cylinder motor. The acceleration has a smoothness comparable with an eight or a twelve. One of the speedsters was driven a distance of 5 miles on high gear with throttle half open and the spark fully retarded. At the conclusion of this test the radiator was still cool enough so that the hand could be kept on the shell without discomfort. The stock car will easily attain a speed of 75 m.p.h. The motor has a bore and stroke of 4⅜ by 6 in.

The cylinders are cast in a single block, which is a departure from previous Stutz practice. The exhaust ports are separated, there being eight ports extended into the manifold. The crankcase is aluminum and the breather is so designed that oil vapor cannot escape and thus dirty the parts.

Ball bearings are used in the pump and magneto shaft bearings. The crankshaft is three bearings. Valves are operated by roller lifts. Cooling is by centrifugal pump and lubrication is force feed through the hollow crankshaft. Pistons are lubricated from the main and rod bearings. The push rods and valve springs are inclosed by aluminum cover plates held in place by wing nuts, allowing removal of the plates without need of tools.

Woman Crosses Continent in 11.23 Days

NEW YORK CITY, Aug. 19—What probably sets a new mark for women drivers was established when Miss Amanda Preuss arrived here to-day, having driven an Oldsmobile stock eight roadster across the continent in 11 days, 5 hr. and 30 min. Miss Preuss was alone in the car and was checked out of San Francisco on Tuesday, Aug. 8, by Major Hilton of the U. S. artillery. The route followed was the Lincoln Highway which, with detours, gave a total of 3600 miles. The longest continuous run was 580 miles from Cheyenne to Council Bluffs.

Master Carbureter Co. Holds National Economy Test

DETROIT, MICH., Aug. 22—The Master Carbureter Corp., this city has just finished a nation-wide economy test with its carbureter in which over 200 of its dealers participated.

The results of the tests appear in the following tabulation and take up a few of the most important cities:

Car	City	M. P. G.
Pope-Hartford	Phoenix, Ariz	31 7/10
Overland 83	Nashville, Tenn	15 3/8
Overland 59	San Francisco, Cal.	20
Cole	Portland, Ore.	12 4/10
Haynes	Salt Lake City, Utah	22 4/10
Buick	Los Angeles, Cal.	22 3/10
Dort	Boston, Mass.	28
Ford	Tulsa, Okla.	24
Paige	Spokane, Wash.	25

Doble Steam Car in Detroit

DETROIT, MICH., Aug. 21—Abner Doble, expert on steam automobiles, who was at one time consulting engineer for the Stanley Motor Carriage Co., makers of steam cars, and who has spent a number of years in the development and perfection of steam propulsion of motor cars, is in Detroit. He has associated with him C. L. Lewis, former president of the Consolidated Car Co., and M. J. Hammers, also connected with that organization. The General Engineering Co. has been organized with a capital stock of $200,000 to market a high class car after Doble's designs.

Resta Easily Wins Speedway Grand Prize

(*Continued from page* 310)

get his car working right and finally withdrew at this point after having been a poor tail-ender in each of the first four heats. He managed to run the requisite five laps each heat, however, and worked on his car between heats to get the kinks out of a valve that insisted on sticking.

There was little contest for first place in the final 50-mile dash, Resta taking the lead at the start and never giving it up but once—at the end of 36 miles Lewis lead but only for a few hundred feet. Likewise there was no doubt from the first who would be the last to finish, for D'Alene could not get his Duesenberg to perform as he had earlier in the race. Resta was never far ahead of Lewis, Buzane and Galvin. These four kept well bunched and the latter three vied with each other for second place and furnished most of the thrills for the final heat. For example, Lewis crossed the tape ten times in second place; Galvin eleven times, and Buzane three. Lewis was third across the tape five times, Galvin ten times and Buzane ten. Fourth place was held by Lewis nine times, Galvin four times and Buzane twelve times.

Security Prices Are Steady

Firestone Common 20 Points Higher—Chalmers Common Rises 10 Points

NEW YORK CITY, Aug. 22—Automobile and accessory issues continued active and strong last week. The tire issues were especially active and several of them made substantial gains. Firestone common featured with a gain of 20 points and closed yesterday at 935. Goodyear common rose 2 points, Kelly-Springfield 2¼ points, Portage 15 points, and U. S. Rubber 2⅜ points.

Chalmers common featured the automobile issues with a 10-point gain, reaching 170. Chevrolet experienced a setback yesterday and dropped to 198, a loss of 14 points for the week. General Motors common also closed yesterday at a loss, this being 10 points.

Springfield Body saw a good demand and rose 10⅛ points as a result of the announcement that the company's earnings are running at a rate equivalent to over 43 per cent on the $1,500,000 common outstanding.

Peerless advanced to 25½ at a gain of 3½ points. This company has just received a large truck order from the Allies.

General Motors preferred reached a new high record of 123 yesterday. It is reported that this company is about to recapitalize on the basis of $75,000,000 common.

Saxon stock rose to 77 at a gain of 5½ points. This company has just announced a large production for the coming year with a large part of it already contracted for. Changes on the Detroit Stock Exchange were for the most part small, ranging from a fraction to 2 points higher. Studebaker common rose to 129½, a gain of 2 points. Maxwell common also rose 2 points, quoting at 82½.

Both the first and second preferred of the Maxwell company rose 1½ points.

Lead and Steel Higher

NEW YORK CITY, Aug. 22—The rise of lead and open-hearth steel featured last week's market activities. Lead rose 70 cents per 100 lb. and Bessemer steel rose $2.00 per ton. Lead quoted yesterday at $6.75 and Bessemer steel at $45.00. The rest of the metals were steady and in good demand. This was especially so with copper which is being ordered for November and December delivery.

Rubber prices were also higher yesterday in sympathy with the rise on the London market. The price of hard Para moved more or less in sympathy with that of plantation, but it has remained at a comparatively high level, due to the restricted supply available. Last week Para rose to 67½, a gain of 1 cent a pound, while Ceylon rose 2 cents to 58½ cents.

Enger Announces New Financing

One Share of 7% Preferred and Two Shares Common for $105

CINCINNATI, OHIO, Aug. 21—The Enger Motor Car Co., this city, which recently took over the Frank J. Enger Co. for the purpose of handling the company's increased business, this week elected the following officers, all of Cincinnati: F. J. Enger, president and general manager; Daniel McLaren, first vice-president; E. L. Jones, second vice-president; and G. W. Platt, secretary-treasurer. The company will begin at once the erection of an additional building which will give it a capacity of 7500 cars per annum.

The directors are as follows: F. J. Enger, E. L. Jones; D. C. Keller, president of the Dow Drug Co.; R. H. Wurlitzer, president of the Rudolph Wurlitzer Co.; L. R. Marks, president of L. R. Marks Co.; Daniel McLaren, president of the Hamilton County Bank; R. B. Goodrich, president of the Engle Mfg. Co.; F. E. Wesselmann, County Commissioner and President First National Bank of Cheviot; A. A. Taylor, vice-president the Stearns & Foster Co.; W. B. Hay, president the Hay Lumber Co.; Edward Ritchie, president the Guarantee Deposit Bank; and

Receiver for McClurg Tire Co.

COSHOCTON, OHIO, Aug. 21—Dr. H. R. McCurdy is appointed receiver for the McClurg Tire & Rubber Co. The receiver's bond was fixed at $25,000 which was given and the receiver took charge. The suit was brought by Jesse McClain, J. S. McClurg, and Dr. L. C. McCurdy. Inability of the company to market its automobile tires is given as the cause for the receivership. J. L. Rue, M. A. McConnell and C. H. Howell were named as appraisers.

—

Allard on Torpedoed Ship

TORONTO, ONT., Aug. 12—M. L. Allard, assistant superintendent of the Dunlop Tire & Rubber Goods Co., Ltd., has just returned to Toronto after a most adventurous trip to Europe and the Far East for the Dunlop company. Mr. Allard was the only Canadian passenger on board the Yasaka Maru when that liner was torpedoed in the Mediterranean. Mr. Allard lost everything and was for hours drifting around on a raft. Finally the party were picked up by a passing steamer.

Redden Truck to Expand

DETROIT, MICH., Aug. 21—The Redden Motor Truck Co. has recapitalized at $500,000 in order to expand its business. It manufactures an attachment for making a Ford into a 1-ton truck.

Capt. Lewis Pays L. P. C. Debts

—

Personal Pledge of 100% to Creditors Redeemed in Full

RACINE, WIS., Aug. 19—Capt. William Mitchell Lewis, former president of the Mitchell-Lewis Motor Co. and later the moving spirit in the L. P. C. Motor Co., Racine, Wis., has fulfilled his promise to creditors of the L. P. C. company that all claims would be paid at 100 per cent of value, regardless of the amount accruing from the sale of assets.

The L. P. C. Motor Co. made a voluntary assignment 11 months ago. At that time Capt. Lewis gave creditors his personal pledge that none would lose even a penny in the transaction. On Aug. 16, last, the assignee, F. Lee Norton, filed in circuit court his report of receipts and disbursements, amounting to $102,000. It was stated that preferred creditors were paid in full some months ago, and checks were mailed to other creditors on Aug. 15 for 100 per cent of their claims, although the sale of assets gave general creditors only 23.7 per cent of claims. The referee states that Capt. Lewis gave him his personal check to make up the balance amounting to 76.3 per cent, thus making it possible to liquidate every cent of the indebtedness.

The Lewis family recently disposed of its holdings in the Mitchell-Lewis Motor Co. to the Mitchell Motors Co.

—

Swiss Exports Valued at $5,790,000 in 1915

BERNE, SWITZERLAND, July 26—Swiss automobile manufacturers closed the year 1915 with exports valued at $5,790,000. By weights the exports of 1915 exceeded those of the preceding year by over 100 per cent, and by value even a larger gain was made. Proportionally the Swiss automobile export industry, it is said, has increased at a greater rate than that of the United States.

Finished trucks and truck chasses formed the principal exports. The former export increased by more than 300 per cent and the latter by 100 per cent. They were sent largely to France.

The imports fell from 1,868,416 lb. to 571,438 lb. Among imported cars the American product is only slightly represented. But three American cars have been seen in this section during the past 6 months.

About 750 cars and trucks are imported annually. The most popular foreign car is the Fiat. Small 10 to 20 hp. five-passenger cars are in greatest demand.

Local automobile dealers declare that the absence of supply stations for American cars is the principal drawback to the sale of such automobiles here. Repairs under the circumstances are expensive.

At least two high-class cars are manufactured in the country, and in normal times these cars sell, even in France, in competition with French machines. The price of these Swiss cars usually is from $1,660 to $2,190, but 15 per cent increase has been exacted by the manufacturers since the war.

—

Chiniquy Heads Kankakee Co.

KANKAKEE, ILL., Aug. 17—R. L. Chiniquy was elected president of the Kankakee Automobile Co., this city, at a meeting of the stockholders held this week. The other officers are: Vice-President, E. Betourne; treasurer, E. C. Chabot; secretary, O. L. Chiniquy; general manager, R. E. Parker. The directors are R. L. Chiniquy, E. Betourne, E. C. Chabot, R. E. Parker, and O. L. Chiniquy.

The company was incorporated for $500,000, and at the election it was reported that over $300,000 worth of stock had been subscribed for.

The plant is located on North Greenwood Avenue near the N. Y. C. tracks. A small six has been assembled and tested. A new model, a larger six, is being worked out in the shop.

—

Brown Takes Lubricating Bolt

SYRACUSE, N. Y., Aug. 21—The Brown Co., this city, has taken an exclusive license to manufacture the automatic lubricating bolt recently patented by David Landau, New York, and H. G. Farr, Springfield, Mass. The lubrication is from a main reservoir wick of felt that is positively attached to a threaded cap plug with feed wicks.

Ollier Taboos Factory Convention

In Favor of Getting Dealers Together in Their Own Territories Less Expense

DETROIT, Aug. 19—Shedding some new light on the matter of conventions of dealers, L. J. Ollier, vice-president and director of sales of the Studebaker Corp., who has just returned from a long trip to thirty-five of the leading cities in all sections of the country where he addressed conventions of the Studebaker dealers, says that the idea of holding one big convention at the factory each year is all wrong. This method of getting the dealers together is quite generally practiced, but Ollier's plan is to hold territorial conventions, where each man gets more individual attention and feels himself a bigger unit in the general assembly.

Ollier points out that if all the 6500 Studebaker dealers were to attend a big factory convention, the expense of bringing them in and entertaining them would be prohibitive. Of course, only a comparatively small proportion of them would attend, probably about 2000. A factory convention would therefore not be representative. A further difficulty is that those dealers who would attend would get lost in the shuffle, so to speak.

With the series of territorial conventions among dealers, it is entirely different. The dealers can afford to leave their business and travel 100 or 200 miles to attend a one-day convention at a branch, whereas they would not feel like traveling 1000 miles or more to go to the factory for a 3- or 4-day convention. At the district conventions, each dealer feels more important, and he gets a chance to talk with the factory officials and realizes his place in the general factory fabric. In a word, the territorial conventions are simply a means of attaining efficiency and reducing waste. They save time for the dealer at a period such as we are now experiencing when he is busy selling cars.

Studebaker, Ollier says, has never held a factory convention that was nearly so satisfactory, and practically every dealer in every district takes advantage of the territorial gathering and there is an element of personal contact that is impossible in annual factory affairs.

$150,000 Addition for National

INDIANAPOLIS, IND., Aug. 21—For the year ending July 1, National Motor Vehicle Co. sales increased more than 300 per cent.

Work has been started on the new $150,000 addition to the factory which made necessary the purchase of one-half a city block east of the present plant. Two new buildings are to be built at once. The new ground is 140 by 410 ft. Most of this ground has heretofore been occupied by one-story houses which must now give way for factory space.

The new building is to be 60 by 380 ft. and three stories high. It will be of reinforced-concrete and steel of the same general design and construction of the new National buildings which were built just 1 year ago.

The other new building will be 140 by 328 ft. and one story high. This building will be erected on the ground recently purchased.

More than 114,000 sq. ft. of floor space will be added to the National factory by the new buildings.

Fuller & Sons Output Increased

KALAMAZOO, MICH., Aug. 22—The new factory of the Fuller & Sons Mfg. Co., this city, is now completed and fully occupied. This company, which manufactures automobile parts and does a large business in transmissions, increased its output in July, 1916, 400 per cent over the same month last year. This output was nearly as great as the entire output of 1914. The production during the first 6 months of 1916 was 1 1/3 times greater than the entire year of 1915. To take care of this large increase in production, the company was forced to greatly increase the number of employees. At the end of July, 1916, the company had 250 per cent more men than in the corresponding month of 1915.

Overland Secures N. Y. Headquarters

NEW YORK CITY, Aug. 21—The Willys-Overland Co., which recently took control of its sales in this city by the establishment of temporary quarters at Columbus Circle, has leased the property at Broadway and Fiftieth Street belonging to the Wendell Estate. This building has remained vacant for 14 years. The Overland company will be the first tenant and will occupy the entire three floors and basement. The company has also opened a used car department at 1700 Broadway, near Fifty-fourth Street.

Trenton Plants Being Enlarged

TRENTON, N. J., Aug. 17—Trenton's manufacturing activity in the automobile industry is indicated by plant additions in course of construction or about to be erected at different establishments.

The Thermoid Rubber Co. has under way construction work designed to double the present capacity of the plant.

The Mercer Automobile Co. is erecting new buildings which will add nearly 100 per cent to its present output facilities.

In addition to other extensions made during the last year, the Ajax Rubber Co. has started work on a four-story steel and brick addition.

Saxon Employees Get Bonus

Will Turn Out Over 60,000 Cars for 1917—Contracts for 50,755 Closed

DETROIT, MICH., Aug. 21—The Saxon Motor Car Corp. will share a special bonus with its employees both in the office and factory departments, in accordance with a new plan just made public. This action is the result of the knowledge the Saxon officials have of the share the employees have in the success of any organization.

Office employees who have been with the concern for a period longer than 90 days will receive a bonus at the rate of 5 per cent of their yearly salary. Factory workers will share on a like basis, with the exception of those who have been paid a premium on the piece work basis. These will get a bonus of 3 per cent. The payment of this bonus will be made Sept. 1.

Although the Saxon organization has not decided upon a policy of bonuses each year, it is the intention, in years of prosperity, to pay some form of bonus as an appreciation of their services.

The idea is to get the employees interested in their work. and to build the best they can, for each step in manufacture is linked with the good-will of the men who actually do the manufacturing or fill the cogs in the industrial machinery.

DETROIT, MICH., Aug. 21—The Saxon Motor Car Corp. plans for an output for the 1917 selling year of more than 60,000 cars. Contracts for 50,755 cars have been closed within the past 3 weeks with Saxon dealers, and it is expected that the coming week will swell this to over 60,000. There is a definite monthly schedule of cars embodied in each contract which constitutes a bona fide order against which the concern can make shipments, which is a new feature for safety in dealer contracts. It is stated that Saxon is experiencing no let-up in the demand for its cars, and more orders for immediate shipment have been received since Aug. 1 than in any similar period in previous years.

Dodge Will Have Carpenter Shop

DETROIT, MICH., Aug. 21—The Dodge Bros. plant is to be enlarged by the addition of a five-story carpenter shop to cost $40,000 and measuring 240 by 40 by 80 ft., a six-story core shop to mean an outlay of $300,000 and having the dimensions of 425 by 60 by 105 ft., and another smaller building, one-story and 24 by 148 ft. Building operations on these will be started immediately.

Factory Miscellany

Superior Castings Plant Nears Completion—Work is being speeded on the erection of the plant of the Superior Steel Castings Co., Benton Harbor, Mich., whose main factory building will occupy a tract of land 138 by 200 ft. It is expected that the plant will be ready for occupation by Nov. 1. As the name indicates, the concern will manufacture steel castings.

No Homes for F. W. D. Employees—Because of the large growth of the business of the Four Wheel Drive Automobile Co., which has made it necessary to bring several hundred workmen to Clintonville, Wis., that city is confronted by a serious housing problem. To afford relief, business men have formed the Home Building Co., with $25,000 capital and will erect a large number of cottages, to be leased or sold practically at cost.

Case Issues New Shop Paper—The 5000 or more employees of the J. I. Case T. M. Co., Racine, Wis., are receiving the first issue of a new shop paper published at the expense of the company and distributed free to all members of the Case company. The paper is a monthly and much space is devoted to discussions of better shop practices, safety methods and topics bearing on the general welfare of the workers.

Rotary Engine Co. Starts Work—The Rotary Gas Engine & Pulverizer Co., which was organized recently at Antigo, Wis., with $25,000 capital, intends to engage at once in the manufacture of rotary gas and steam engines, tractors, transmissions for automobiles and other mechanical devices. The design is by Clarence Rishel, Denver, Colo., who has come to Antigo to take charge of the manufacture. For the present the production will be done under contract with local machine shops and foundries.

Continental Truck's New Plant—The Continental Motor Truck Co., Superior, Wis., has broken ground for its new $50,000 factory at Belknap Street and the Soo line tracks. The shop is to be ready Nov. 1, at which time the output of trucks will be largely increased. Dr. J. G. Barnsdale is general manager.

Boone Tire to Build—The Boone Tire & Rubber Co., Des Moines, Iowa, has practically concluded negotiations with the Business Men's Association to establish a branch plant in Beloit, Wis., to cost $25,000. The Iowa company is capitalized at $500,000 and operates a large tire and rubber works at Des Moines. This is overcrowded, however, and a branch plant must be provided. It is the intention of the company to build a plant.

Aluminum Co. Adds—The Werra Aluminum Co., Waukesha, Wis., which supplies numerous motor and automobile manufacturers with aluminum crankcases and other castings, is having plans prepared for a foundry addition, made necessary by the demand for its product.

Neverleek Co. Builds—F. S. Carr Co., Boston, Mass., maker of The Neverleek, is putting up two new buildings. The contract has been given and work will be started in Framingham at once.

Agnew Joins Chalmers—W. L. Agnew, who was the advertising manager of the Hudson Motor Car Co., Detroit, Mich., during the past 4 years, has joined the Chalmers Motor Car Co., where he will be connected with the sales promotion department.

Coey School to Build Plant—The Coey Auto School, 2010 South Wabash Avenue, Chicago, will build a one-story automobile factory to cost $50,000.

Chester County Motor Co. Moves—The Chester County Motor Co., Coatesville, Pa., will move to Philadelphia, Pa., where its plant will be located at Cherry Street, near Fifty-eighth Street. This company, of which J. E. Brinton is president, has been manufacturing a light gasoline commercial vehicle.

The Automobile Calendar

ASSOCIATIONS

Aug. 28-Sept. 1 — Milwaukee, Wis., Booster Tour of Milwaukee Automobile Dealers.

Sept. — Indianapolis, Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.

Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.

Oct. 2-7—Kansas City, Mo., Dealers' Show, American Royal Live Stock Show; Kansas City M. C. Dealers' Assn.

Oct. 13—Flint, Mich., Fall Meeting National Assn. of Automobile Accessory Jobbers.

Dec. 2-9—Electricians' Country-wide Celebration.

CONTESTS

Aug. 26—Kalamazoo, Mich., 100-Mile Track Race.

Sept. 1-2—New York, N. Y., Sheepshead Bay Speedway, 24-Hour Race, Trade Racing Assn.

Sept. 4—Elmira, N. Y., Track Race, Elmira Auto and Motorcycle Racing Assn.

Sept. 4—Cincinnati, Ohio, Speedway, Cincinnati Speedway Co.

Sept. 4—Newark, N. J., Track Race, Olympic Park, Racing Assn.

Sept. 4—Des Moines Speedway Invitation Race. Limited to six entries.

Sept. 4-5 — Spokane, Wash., Track Race, Inland Auto Assn.

Sept. 9—Indianapolis Speedway Race.

Sept. 16—Providence Speedway Race.

Sept. 18—North Yakima, Wash., Track Race, Washington State Fair.

Sept. 29—Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.

Sept. 30 — New York City, Sheepshead Bay Speedway Race.

Oct. 7—Philadelphia Speedway Race.

Oct. 7—Omaha Speedway Race.

Oct. 14 — Chicago Speedway Race.

Oct. 19—Indianapolis, Ind., Race, Indianapolis Motor Speedway.

Oct. 21 — Kalamazoo, Mich., Track Races, Kalamazoo, Motor Speedway.

Oct. 22-23—Los Angeles, Cal., Commercial Car Reliability Tour.

Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

GOOD ROADS

Sept. 1-9—Cincinnati, Ohio, Good Roads Exposition and Convention, Music Hall, Hamilton County Dixie Highway Council of Cincinnati.

Sept. 6-7—St. Paul, Minn., Good Roads Congress, Auditorium.

SHOWS

Sept. 2-9—Cleveland, Ohio, Show, Industrial Exposition and Fair, Edgewater Park.

Sept. 2-9—Columbus, Ohio, Fall Show, Ohio State Fair, Columbus Automobile Show Co.

Sept. 4-8 — Hartford, Conn., Show, Connecticut Fair Assn.

Sept. 4-9—Minneapolis, Minn., Show, State Fair.

Sept. 4-11 — Indianapolis, Ind., Show, Indiana State Fair, Indianapolis Automobile Trade Assn.

Sept. 10-16 — Milwaukee, Wis., Show, Wisconsin State Fair, Machinery Bldg.

Sept. 25-30—Salem, Ore., State Fair, Joseph M. Rieg, manager.

Oct. 14-31 — Dallas, Texas, Show, State Fair.

Jan.—First Pan-American Aeronautic Exposition, New York City; Aero Club of America, American Society of Aeronautic Engineers, Pan-American Aeronautic Federations.

Jan. 6-13, 1917—New York City, Show, Grand Central Palace, National Automobile Chamber of Commerce.

Jan. 13-20 — Montreal, Que., Show, Montreal Automobile Trade Assn.

Jan. 27-Feb. 3, 1917 — Chicago, Ill., Show, Coliseum, National Automobile Chamber of Commerce.

Feb.—Newark, N. J., Show, First Regiment Armory.

Feb.—St. Louis, Mo., Show, Auto Manufacturers' and Dealers' Assn.

Feb. 3-10—Minneapolis, Minn., Show, Minneapolis Automobile Trade Assn.

Feb. 26-March 3—Omaha, Neb., Show; Auditorium, Omaha Automobile Show Assn.

TRACTOR

Aug. 21-25—Bloomington, Ill., Tractor Demonstration.

Aug. 28-Sept. 1—Indiana Tractor Demonstration.

Sept. 4-8—Madison, Wis., Tractor Demonstration.

Sept. 11-16 — Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.

The Week in the Industry

Ramsden With Oakland.—J. M. Ramsden, formerly with the implement departments of the J. I. Case Plow Works, Racine, Wis., also the Moline Plow Co., and the Kingman Plow Co., is now a general traveler with the Oakland Motor Car Co., Pontiac, Mich.

French Bour-Davis Purchasing Agent—W. F. French has been appointed purchasing agent of the Bour-Davis Motor Car Co., Detroit. Mr. French is a newcomer in the automobile field, but has been associated in the mercantile and commercial fields in Chicago in a similar capacity.

Riess to Move Sept. 15 — Charles E. Riess, Hupmobile distributor in New York City, will move to 1741 Broadway about Sept. 15, at which address his organization will occupy all four floors. The service station, which will continue at 226 West Fifty-sixth Street, will be enlarged and improved.

Overland to Open Cafeteria — The Willys-Overland Co., Toledo, Ohio, will open a cafeteria about Sept. 1 for nearly 1000 office employees. The cafeteria will be opened simultaneously with the removal of the offices to the new seven-story office building, just completed, on the Boulevard, near West Toledo.

Mason Plant Leased by Ford—The old Mason Motor Car Co. plant, Des Moines, Iowa, has been leased as temporary headquarters for the Ford branch assembly plant for Iowa, which ultimately will be located in a new building at Eighteenth and Grand Streets. The old Mason plant has about 20,000 ft. of floor space.

Canadian Items — The Canadian Double Tread Tire Co., Vancouver, B. C., has removed to 1260 Granville Street.

The Vancouver Motor Co., Vancouver, B. C., has removed to 825 Pender Street.

J. H. Beaton, former assistant sales manager of the McLaughlin Co., Oshawa, Ont., has been appointed to the above position for all of Canada. This company trebled its output in 1916 and will double the output for 1917.

Bour Sells Advertising Interest—C. J. Bour, president of the Bour-Davis Motor Car Co., Detroit, and former head of the National Railway Advertising Co. of Chicago, has become so interested in the automobile business that he has disposed of his interests in the Chicago company. Mr. Bour will devote a great deal of his time to the automobile business, spending the weeks in Detroit and the week-ends in Chicago at his home.

Ohio News Items—The Central West Motor Car Co., Columbus, has taken the central Ohio agency for the Liberty car.

The Broad-Oak Automobile Co., Columbus, will act as central Ohio distributor for the Studebaker. The distribution of the Studebaker was formerly done by the Brasher Motor Car Co.

The Toledo Central Garage Co., Toledo, has purchased the stock of Oakland and Hollier cars from the Toledo Auto Sales Co., and will operate the business in the future.

The Kissel Service Co., Columbus, has taken a lease on a new building on the southwest corner of Spring and Fourth Streets, where the salesrooms and service station will be located.

Philadelphia Items—The Hawley Motor Co., 632 North Broad Street, increased its capital stock from $50,000 to $250,000.

C. W. Mann, for 10 years with the Buick Motor Co., Philadelphia, has opened a Buick agency at 322 West Main Street, Norristown, under the name of the Charles W. Mann Motor Co.

G. H. Patterson, formerly with Hurley & Early, Philadelphia, has been promoted to sales manager of the Lexington Motor Co., 150 North Broad Street. The latter, it is announced, will be in new, larger quarters by fall.

The Remey Motors Co. has been organized here by Robert Remey and A. P. Whitman, who will distribute the twelve-cylinder H-A-L in Pennsylvania, New Jersey, Maryland, Delaware, Virginia and West Virginia.

Northwest News—The Twin City Cord Tire Co., Minneapolis, has amended articles of incorporation permitting increase in capital to $250,000.

The Chevrolet Motor Co. of Minnesota, Inc., is the name of a new factory branch, Minneapolis, opened by the Chevrolet Motor Co. to give service, distribution and repair parts depot for Minnesota, North and South Dakota, western Wisconsin, Montana, Iowa, Nebraska and Wyoming. Address is Sixth Avenue South and Fourth Street.

The Goodrich Tire Co., 506 Andrus Building, Minneapolis, has begun construction of the first unit of a factory at Redwing, Minn. It will cost $75,000, will be three stories, 100 by 100 ft. The capital is $300,000. Officers are: President, H. Scott Ewers; secretary, F. E. Oberg; superintendent, H. J. Smith. The company will make tires and mechanical rubber goods.

New England Trade Items—Connell & McKone, Eastern Massachusetts dealers for the Overland, have opened a salesroom on Main Street, Worcester, Mass.

The Ford Motor Co. has opened its new branch at 75 Liberty Street, Springfield, Mass.

R. O. Spiller has been appointed manager of the Franklin Square Motor Car Co., Dover, N. H.

The Becker-Stutz Co. of Boston has leased a large building at Springfield, Mass., for its branch there.

F. H. Kenney, who has the Chalmers at Worcester, Mass., has moved into new salesrooms.

G. D. Niles has been appointed manager of the Boston branch of the Portage Tire Co.

W. C. Goodchild, formerly manager of the Metz company's branch at Providence, has been made manager of the Boston branch.

P. S. Clark, secretary-treasurer of the Rhode Island Automobile Dealers' Association, and formerly the Mitchell agent at Providence, has formed a new company to handle the Apperson automobile there.

The Pennsylvania Rubber Co. has moved its New England branch at Boston to a new structure on Beacon Street.

Frank Crockett, for a long time with the Knox company, has joined the Connell & McCone Co., to have charge of their Overland service station.

The big Overland service station at Portland, Me., was finished last week, and a similar one is to be built at Bangor.

J. W. McGuire, Pierce-Arrow dealer at Boston, Mass., has had a set of plans drawn for a service station that will cost more than $100,000.

Alvan T. Fullerr, who has the Packard agency for Eastern New England, has just signed a contract for an addition to his mammoth service station in Boston, Mass., that will be a duplicate of the present one. It will be connected with the other by a bridge of U shape, leaving an 80-ft. court between the two buildings. The additional structure will give him 150,000 additional sq. ft. of floor space, and make it what is claimed to be the largest plant in the country controlled by one dealer. The first floor of the new building will be for the used cars, and the rest for a service station. The cost will be about $250,000, making the total plant worth more than $500,000.

A Cowl Board With Every Speedometer for Ford

Just what every Ford owner needs, and wants—a Cowl Board beautifully finished in black enamel with a Stewart Speedometer, set off with a heavy nickel flange, mounted in the center.

It's a beautiful job.

And it gives a finished appearance to the Ford dash—and brings the speedometer up in a position where it can be easily read—even at night.

Ford owners are going to literally snap up this new Stewart product as soon as they see it. It is put on so easily—and is such a marked improvement. And the price complete is only a trifle more than the cost of the speedometer itself.

Dealers. think of the market this new Stewart Product opens up for you.

Speedometer for Ford $10

Cowl Board $1.25 Price Complete $11.25

"It will pay you to see that the car you buy is equipped with Stewart Products"

Cashing in on an Ill Wind

Railroad Strike Would Mean Opportunity to Cars and Trucks

NEW YORK CITY, Aug. 30—Should the threatened national railway strike materialize, automobiles and motor trucks will be offered the greatest opportunity in the history of the industry to demonstrate their ability in practical inter-city service. Already every city in the country is turning to the automobile as a possible means of passenger travel. More important still, these cities are looking to the motor truck as a means of furnishing their populations with food and other necessities from which the cessation of railroad operation would cut them off.

For Inter-Urban Work

Passenger lines may be organized for inter-urban transportation and if the strike should prove of appreciable duration these lines could be arranged without difficulty to form a network covering practically all the more thickly settled portions of the country.

The same applies to motor trucks so that passengers and goods could be carried from Boston to New York by one line, for example, and thence by another line, or perhaps a continuation of the same one, to Philadelphia and so on to Baltimore, Washington, etc. Chicago and Detroit, Buffalo and Cleveland and other large centers not separated by too great distances could be similarly supplied. Operation in a commercial way on such a large scale would do much in proving to the general public the efficiency and economy of the modern automobile and motor truck.

Car, truck and accessory manufacturers, like all other industries, would be handicapped in making deliveries if the railroads stopped running but in the case of the cars and trucks, these could be delivered under their own power in the form of driveaways from the factories to points not too far removed. Accessories would have to be shipped by motor trucks like all other commodities.

—

Chevrolet $490 Electrically Equipped —Baby Grand $50 Higher

NEW YORK CITY, Aug. 26—The Chevrolet Motor Co., this city, has raised the price of its Baby Grand model from $750 to $800 and also announces that hereafter the price of $490 for its small model, known as the Four-Ninety, will include electric light equipment and electric self-starter. Heretofore, the Four-Ninety model equipped with electric lights and starter sold at $550.

—

Daniels Price Raised $200

NEW YORK CITY, Aug. 28.—The price of the Daniels eight will be increased on Sept. 1 $200, to $2,800 on all models.

—

Lozier Resigns as H-A-L Head

CLEVELAND, OHIO, Aug. 29—H. A. Lozier has resigned as president of the H. A. Lozier Co., this city, maker of the H-A-L twelve.

—

Murphy Resigns from Chalmers

DETROIT, MICH., Aug. 28 — Gail Murphy, advertising manager of the Chalmers Motor Co., has resigned.

—

Jones with Federal Brass Works

DETROIT, MICH., Aug. 28—The Federal Brass Works has appointed L. P. Jones sales manager.

—

Hebner Joins Bearings Service Co.

DETROIT, MICH., Aug. 28 — A. K. Hebner, service supervisor of the Hyatt Roller Bearing Co., has resigned to become general manager of the Bearings Service Co.

Haynes Sold to N. Y. Syndicate?

$4,500,000 for Stockholders in Addition to Half Stock of Holding Company

INDIANAPOLIS, IND., Aug. 29—By a deal made last week the stock of the Haynes Automobile Co. of Indiana may be taken up by the Haynes Automobile Co. of New York, a holding corporation, a consideration of $4,500,000 being paid to the stockholders of the Indiana corporation, in addition to receiving half of the stock of the holding company. Plans already are under discussion for placing a cheaper car on the market, to be known as the Junior Haynes.

Horace C. Stilwell, a promoter of Anderson, Ind., who represents New York financiers, signed an agreement with the stockholders of the Haynes company on Aug. 23. The agreement provides that 90 days shall be given the New York group to consummate the deal. The holding company is to have 600,000 shares of stock. Each stockholder in the present Haynes company is to receive six shares of the holding company's stock for each share of the present stock. It is proposed to place the other half of the holding company's stock on the market. The agreement provides that the present stockholders are to elect half of the board of directors.

According to announcements coming from Kokomo, A. G. Sieberling, who has been manager of the company for the last 3 years, and his assistants will remain in charge should the deal be consummated.

—

Dodge Resigns from Houk

BUFFALO, N. Y., Aug. 28.—L. G. Dodge has resigned as general sales manager for the Houk Mfg. Co., this city, to take effect Sept. 1.

Lamp Standards Are Progressing

S. A. E. Experiments Approach Solution of Glare Problem—May Eliminate Focusing

NEW YORK CITY, Aug. 29—It is thought possible that the experimental work now being done by the electrical equipment division of the S. A. E. standards committee may result in a great reduction of glare in headlamps and also in the elimination of all focusing devices. A focusing device is only an adjustment to counteract the ill effects of inaccurate reflectors and lamp bulbs. Experiments made at Nela Park, Cleveland, by a committee of the division some months ago showed that certain types of bulb filament and certain types of reflector were less sensitive than others, that is to say, they found it possible with some bulbs and reflectors to alter the adjustment of the focusing device quite considerably without affecting the nature or quality of the light seriously.

Another meeting held at Cleveland last week discussed the results of the tests having full specifications of the best bulbs and reflectors before them, and ascertained that it is possible commercially so to make bulbs and reflectors that any pair will assemble correctly without individual focusing.

The essential with respect to the bulb is that the filament shall be truly central within fairly fine limits, and for the reflector the focal length must be close to 1¼ in. With a reflector accurate in form within the limits of normal manufacture and with a bulb just a little more accurate than the present average and the right shape of filament no focusing is necessary.

Size of Filament

The committee on lamps reported the results of their meetings to the whole electrical equipment division at a meeting here to-day and the following subcommittee report and suggestions were approved:

The vacuum bulb which was selected as most practical at the tests had a filament in the form of a helix 2.5 mm. in diameter and 4.2 mm. long. The gas-filled bulb which was selected had a V shape filament, the spread of the V being 3 mm. and the height 2.5 mm. Both of these were 2½ amp. bulbs.

The National Lamp Works is making both 1½-in. and 2-in. bulbs with filaments located the same in reference to the base. Filaments are located by eye in manufacture, and the variation is held within 1/16-in. plus or minus. If jigs are introduced to secure more accurate location, the expense will be greater and the manufacture slower.

It is possible to locate the centers of filaments within 1/64 in. of the true axis and within 1/32 in. of standard distance from the pins in the base. Figures will be furnished as to the approximate increase in cost per bulb if they make the necessary apparatus and perform the necessary operations to locate centers of filaments within these limits.

The subdivision tentatively recommends that for all headlamp bulbs the center of the filament be located in the axis of the bulb, 1¼ in. from the nearer or locating side of the locating pins of the base.

Vacuum bulbs are to have filaments in the form of a helix 4.2 mm. long and 2.5 mm. in diameter.

Gas-filled bulbs are to have filaments in the form of a V (each leg of the V being formed of a fine helix) 3 mm. wide at the base and 2.5 mm. in length. The plane of the filament is to be at 90 deg. from the plane of the locating pins.

These tentative recommendations are to be tested out under manufacturing conditions by the latter part of November, after which time the final report can be made.

Reflectors

The subdivision recommends that reflectors be made as near as possible to the outline of a true parabola of 1¼ in. focal length. The receptacle shall be located concentric to the reflector and so that at the central point of adjustment in the reflector the portion of the bayonet slot where the pin comes to rest shall be 1¼ in. from the focal point of the reflector.

Tail-Lamp Glasses

Investigation has shown that practically all makers of tail lamps are using glasses having a nominal diameter of 3 in. with tolerance of minus 1/64 and plus 1/32 in. It is recommended that these dimensions be made standard.

American Junior to Compete with Jinrikisha

INDIANAPOLIS, IND., Aug. 30—The American Junior, a little car carrying two passengers, is to be built here to compete with the jinrikisha in China and for juvenile trade. This car, with a 40-in. tread and a 70-in. wheelbase, will be built by the American Motor Vehicle Co., Lafayette, Ind., beginning Sept. 1.

The company will also manufacture motor chairs, which are driven by storage batteries. The directors are Jacob Weisenthal, Lafayette, president; Louis Marx, Chicago, vice-president; and W. M. Crockett, Lafayette, secretary. B. J. Mills, Chicago, is one of the principal stockholders. The capital is $25,000.

S. A. E. Session in Show Week

1-Day Professional Session with 2 Days for Committee Work—Dinner Thursday, Jan. 11

NEW YORK CITY, Aug. 28—According to the plans now under discussion, Tuesday, Wednesday and Thursday of New York show week in January are the days that S. A. E. members should bear in mind. They are the days of the annual mid-winter meeting. This year the New York automobile show is held a week later than formerly, so that the New Year's holidays are not molested as they have been for years past.

The show week begins Saturday, Jan. 6, and ends the following Saturday night, Jan. 13.

The annual S. A. E. dinner, the social feature of the week, will surely be held in Hotel Biltmore on Thursday evening, Jan. 11. The grand ball room with capacity for 750 guests has been selected because in connection with this hall are other large reception halls that have accommodation for that number.

As a climax to the dinner the Society through its 1916 Meetings Committee has secured the Midnight Frolics for that night, practically the entire seating space being reserved for S. A. E. members and guests.

Thursday will be the big day for professional papers, discussions, etc. The session will start at approximately 10 a. m., the official morning hour for New York show week and the work will be over at 4 p. m. At noon there will be a buffet luncheon. This session will be held in the large assembly room of the Engineering Societies Building.

Although Thursday will be the big Society day of the week, the work of the session will start Tuesday, when the many committee divisions of the Standards Committee will meet and add the finishing touches to their various reports.

Wednesday will be an important day. In the morning at 9.30 will be held the usual business session for various reports such as membership, treasurer, election tellers, the discussion of constitutional amendments and other work. After this short business session of an hour the various reports of the Standards subcommittees will be presented for final action by the Society. This will occupy the remainder of the forenoon.

Wednesday afternoon will largely be given over to a consideration of aviation matters. There will be at least two important papers on aeronautical topics, and these will be followed by three 15-minute discussions on important aviation subjects, to be announced later.

Illinois Farmers Want Tractors

Their Problem Is Quest for Best Size and Type—Too Many Models

BLOOMINGTON, ILL., Aug. 25—The Illinois farmer wbo visited the 5-day tractor demonstration held here tbis week is not concerned over whether he shall buy a tractor or not. He has already settled that question. He has made up his mind that he must have a tractor and he is going to buy one. The problem that is worrying him to-day is what tractor he will buy. His vexing problems are what size of machine, and what type of machine. Size and type confuse him immeasurably.

Tbe attendance was much larger than exhibitors had anticipated. The opinion was expressed very freely that although the numbers were not quite so great as at Fremont, the demonstration was quite as successful, from a business point of view. Perhaps the reduced attendance may partly be explained by the fact that Henry Ford and his new tractor were not present.

The attitude of the farmer toward tractors was well answered by the fact that at Wednesday's demonstration more than 5000 automobiles were on hand, a large percentage of these representing farmer machines.

Standards Needed

One of the most serious handicaps to the more rapid development of the tractor business is the very apparent uncertainty of tractor manufacturers as to the most suitable type of tractor. Frequently a farmer asking for information finds that he cannot get any convincing advice regarding the size of machine best suited to his requirements. The position is not improved by the attitude of more than one of the old implement manufacturers, as several of these concerns are making a needlessly wide range of machines. When one firm has six machines all quite different, the tendency is to put it up to the farmer to decide what he wants rather than to advise him to have one or another. When it is obvious that the manufacturer has not made up his mind as to which is the best type the farmer's confidence is naturally not very swift in coming.

The variation in type is certainly holding back the sale of tractors because the technical arguments placed before the farmer by different manufacturers are so antagonistic. For example, the champions of the very low-speed and the moderately high-speed engines are very bitter regarding each other, and the farmer cannot possibly reconcile the statements made by the two camps. It is the same with different systems of transmission. The tractor is nowhere near the stage of development reached by the automobile and the least discerning can readily perceive this. Consequently the more the tractor men get together and the more closely they agree from the broader features of design the easier will it be for tbe farmer to make up his mind and the greater the number will be sold.

Brown-Lipe Gear Buys Deere Plow Plant

SYRACUSE, N. Y., Aug. 25.—As a starter to practically doubling its output, the Brown-Lipe Gear Co. has purchased the Fayette Street plant of the John Deere Plow Co., this city. The new purchase gives this company an entire block of its present plant on Fayette Street.

Last week the executive offices were moved into what were the executive offices of the plow company, and as rapidly as the change can be made the grinding department, control set department, tool room, rough stock department and service department are being taken out of the old plant and moved into part of the new plant. The balance of the new plant is being equipped with new machinery and the entire new plant will be in full swing by the first of the year.

—

U. S. Truck Capital $1,000,000

CINCINNATI, OHIO, Aug. 24.—Increased from $300,000, the capital of the United States Motor Truck Co. is now $1,000,000. This increase was made at the annual meeting beld here recently. The new stock is both preferred and common, the preferred being 7 per cent cumulative and participating with tbe common up to 10 per cent. A part of the issue has been subscribed to by present stockholders and an additional block offered to the public.

Besides the regular 7 per cent dividend on the preferred the directors have placed an additional sum in surplus. The company was established 7 years ago and in 1914 was reorganized with R. C. Stewart as president.

—

Parker Collapsible Rim Corp. Formed with $5,000,000 Capital

DOVER, DEL., Aug. 24—A charter has been filed here by the Parker Collapsible Rim Corp. to manufacture and deal in and with rims and parts of automobiles and other vehicles. The capital is $5,000,000.

—

Perkins-Campbell Adds 10,000 Sq. Ft.

CINCINNATI, OHIO, Aug. 25—The Perkins-Campbell Co., this city, has added 10,000 sq. ft. to its factory. A second additional building with over 8500 sq. ft. is being rushed and will be added to the plant about Sept. 15.

Republic Truck Expands

Offers $750,000 of 7% Cumulative Preferred for Expansion of Business

NEW YORK CITY, Aug. 26—Conservative financing has been undertaken by the Republic Motor Truck Co., Alma, Mich., in offering $750,000 of 7-per cent cumulative preferred of $100 par, tbrough George H. Burr & Co. of New York.

Of an authorized capitalization of $1,000,000 preferred stock, $750,000 has been issued. None of the 62,500 shares of common which are authorized has been issued, nor has it any par value.

Financial Condition Sound

The exceedingly sound financial condition of the Republic company is indicated by the fact that it has no bonded indebtedness, nor can it have any except by consent of tbree-fourths of the outstanding preferred stock. Similar referendum is required in order to increase the preferred beyond that already authorized.

The company was established in July, 1913, with a paid-in capital of $8,000. Its capital and surplus, prior to the sale of this latest issue of preferred stock, was $852,219.98, $269,300 of which represented cash contributed from time to time. Dividends of $198,717 have been paid.

The entire proceeds of this issue of stock will go into the treasury of the company to care for the development of its business, the nature of which has been rumored, but not officially made public. According to an audit by Price, Waterhouse & Co., the balance sheet as of June 30, 1916, with the addition of the new capital, will show tangible assets of over 210 per cent and net quick assets of more than 169 per cent of the preferred issue. The certificate of incorporation requires that the net quick assets must be at least 100 per cent of the outstanding preferred.

Net earnings for the fiscal year ending June 30, 1916, according to Treasurer George W. Moore of the Republic company were $530,593.66, or ten times the requirements for preferred stock dividends.

The company has 407 agents, of whom 309 are exclusively devoted to the sale of Republic trucks. In tbe first 6 months of the concern's existence, from July 1, 1913, to Jan. 1, 1914, fifty-four trucks were sold. In the calendar year of 1914, 376 trucks were sold. In 1915, 1855. In the first 6 months of 1916, 2780. Since the beginning of the war, 4837 trucks have been sold, of which but 212 were on war orders.

ACCESSORIES In South America

No. II

Dealers Need Batteries, Jacks, Garage Tanks and Air Compressors—Oils and Greases Find Ready Market

By David Beecroft

IN addition to the spare parts, accessories and speedometers reading in kilometers wanted by the Ford dealer in Cordoba, Argentina, as mentioned in the first part of this article last week, he wants some form of constant lighting electric system for Fords, his request being only one of many similar ones received. Ford has been selling over 300 cars per month in Argentina, Chile and Uruguay. One month it rose to 470 cars; that was last February. With this output there is certainly a large demand for lighting as well as starting outfits. The people buying Fords have generally plenty of money. They are so pleased with the way the cars perform as compared with the impossibility of using the expensive European cars that they are glad to get anything additional that aids them.

Batteries Follow Cars

More U. S. A. starting and lighting batteries are needed. We must have them for nearly all of the 800 cars. Batteries are sure to give more or less trouble in Argentina. They gave us trouble in the U. S. A. the first year or so of electric starters, simply because our owners did not give them the attention they should have—generally distilled water when needed. That trouble is facing Argentina. Everywhere our batteries were conspicuous by their absence. We saw the Willard in several places, only one or two in a place; a few Vestas and a few Exides. There were more French batteries, and we were generally told of the superiority of the French types. It reminded us of the fact that we must look to our own interests in this work. Our battery people will have to fortify themselves in Argentina, Brazil, Chile, Uruguay and many other South American countries, as well as in the West Indies. In the fiscal year we shipped 4444 cars to Argentina alone. We shipped to all of South America 6725 cars. Those that were Fords have no batteries but are in the market for batteries, starters and lighting outfits. We shipped to the West Indies 4658 cars, making a total of 11,383 to Latin America. Spanish instructions on how to take care of batteries will be needed in all of this field excepting Brazil, where Portuguese is needed.

Metal running-board boxes are good sellers.

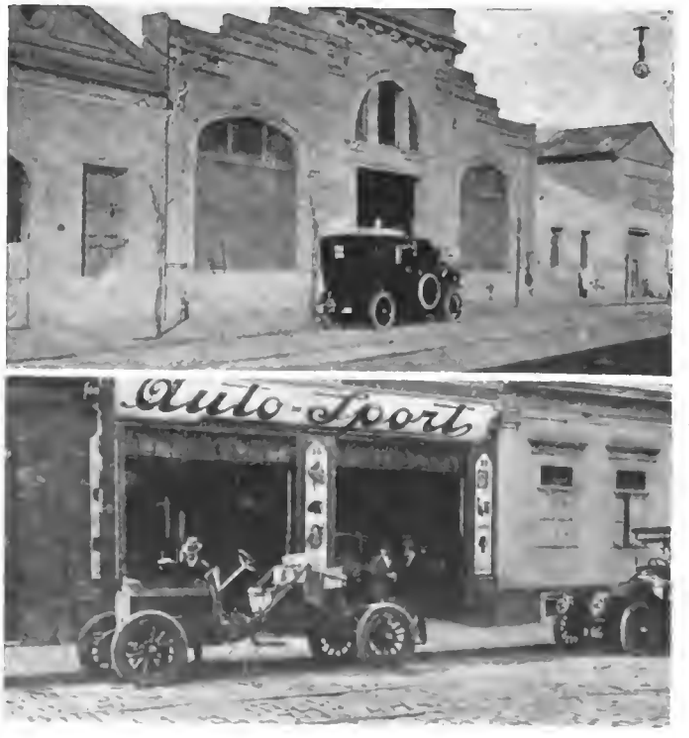
Market for Jacks

There is a good market for jacks in Argentina. You see French and English types and a few U. S. A. varieties. One English jack with a long handle for easy operation was selling well. A Paris jack was also much in demand. Two or three U. S. A. houses were well represented, but the field can be exploited much further.

We might go on indefinitely through the accessory field endeavoring to show different lines of possibilities for our accessory makers. We could add gaskets of all kinds and sizes; wrenches and screwdrivers and like tools, which have largely been supplied by France and Belgium; clocks, which are in demand; tire-removing tools, tire-repair kits, and a score of others. Space will not permit. Enough has been said to suggest the remainder.

Tank System for Garages

A word on garage equipment. Up to the present all of South America has bought gasoline in the square 5-gal. can, two cans being crated together. This is the English system.



Upper—Typical garage in Montevideo in which accessories are sold in large quantities. This is modern building constructed expressly for garage uses

Lower—Auto-Sport is one of the large accessory houses in the City of Sao Paulo, Brazil. It handles all lines of accessories and is much interested in U. S. A. lines. Our cars have been good sellers in the State of Sao Paulo and the accessory market should be proportionately good

Previous to the war England supplied practically all of the gasoline to South America, but now the U. S. A. supplies all and still supplies it in the 5-gal. cans. This is a costly and unhandy way, and the movement is gaining headway to sell in bulk, as is done in the U. S. A. The first curbside gasoline pump in Buenos Aires was started in May. It was proving popular. Argentines may be a little slow in installing new devices, but they are not slow in grasping their advantages. The "you-are-next" rule was in force before it was in place a week. Bowser has a good representation in Buenos Aires, and by this date perhaps several curbside ones are in place.

Not a garage in Buenos Aires in June had gasoline pumps and bulk systems, but they are all in the market for such. Here is a real field, not only in all of Argentina but in all of South America and the West Indies as well. You can add much of Australia. The garage people are a little afraid of the price but are convinced that tanks will have to go in, and we hope that in a year or so the gasoline curbside pump in front of the garage in Buenos Aires will be as common as in our own cities.

Garage Air Compressors

There is a good chance for manufacturers of air compressors for garages. I could not find a garage in any South American city that had a compressed-air system for tire inflation. You have to use the hand tire pump every place. Our makers should get busy with this market. The air system is needed just as much in South America as in the U. S. A. Perhaps smaller systems may be needed. Generally the garages can accommodate fifty to 100 cars. You rarely find larger ones. Our makers should bear this in mind.

Nearly all garages in South America are good centers for selling accessories. They are generally immaculate so far as cleanliness is concerned. They are lessons to us in the U. S. A. in this respect. The manager invariably has a clean business office, and you never see the chauffeurs hanging around. There is invariably a good show window for accessories and generally a very large glass showcase for them. The chauffeurs are in the habit of buying many accessories from the garage.

One bad thing about South American accessory business is that the chauffeurs invariably try to collect 10 per cent commission on all goods bought. They do it on tires as well as on supplies. Added to this is the fact that accessories are generally sold on 90 days. The garagemen and supply-house men would like to eliminate the chauffeur's commission but have not been able to get together in a satisfactory way to do it.

Oils and Greases Sell Well

U. S. A. oils and greases are generally good sellers in South America. One or two brands have good blue-and-white or yellow-and-white enamel signs that you see in most of the garages and supply houses. Generally oil and grease are handled by large concerns that have their own representatives in Argentina and Brazil. Previous to their establishing themselves there were many troubles, and still are. One of the commonest abuses was U. S. A. oil companies not sending the grade of oil ordered. We saw one shipment of oil that was entirely too thin. The shipment was not according to order. Apparently the oil man in New York thought he knew better than the Rio dealer. The result was that the dealer started buying from an oil company that would ship him the grade of oil he wanted. He ordered in $3,000 lots.

Another example was that of a grease shipment which did not come as per order. It was necessary to buy a supply of thicker grease and mix with the first order. On a successive order the price was raised on the Sao Paulo dealer. The result was that now he buys his grease in bulk from Europe—he is still able to get it—and he has made his own cans with his own labels and markets the grease under his own name. He has no objection to selling U. S. A. greases, but the prices must be lower.

Upper—This is one of the largest automobile accessory houses in Montevideo, a city of 375,000 population and the capital of Uruguay, which, although the smallest country in South America, and having a total population of 1,300,000, is a very active motor car country and has more miles of improved highways than any other country in South America, Brazil and Argentina included

Middle—This reproduction of the Overland agency in the City of Rosario, Argentina, shows how car dealers generally handle accessories and display them in the window. Inside there is invariably a good showcase well stocked with accessories

Lower—Casa Tonglet is one of the several large automobile accessory houses in the City of Sao Paulo, Brazil. This house handles U. S. tires for the State. It carries a varied line of accessories but is not so strong in U. S. A. accessories as it should be

Still another example of where our prices will have to be lowered was the case of carbide in Sao Paulo, Brazil. The dealer bought it through a New York exporting house, paying 36 milreis per unit in Santos, and on top of that he had to pay the freight from Santos to Sao Paulo. He was able to buy it from a German house in Sao Paulo for 34 milreis per unit, with no freight.

Bad Business Examples

In a trip visiting a score of supply houses you meet with many examples of bad business. Very frequently these supply houses buy through exporters who sell them goods that are not trade-marked and there is no possible way of telling where they were made. I saw one shipment of a dozen hand horns, and out of the dozen eight would not make a single note. There was no name on the horns and no way

of telling where they were manufactured. The dealer went back through the exporting house, but had not got any redress at the time I saw him.

Another example was an oil shipment in a camp town in Argentina. The oil was in 5-gal. cans with a New York label. The oil was so thin that it was useless. Trade records show no New York house of the name carried on the label. The job may have been put up by some house that was simply exploiting foreign trade. It was a bad advertisement for us.

All cases of this kind hurt U. S. A. goods. Their bad odor travels far and wide. It is no wonder U. S. A. accessories are not so much in demand in some places as they should be. We want our best men in South America to establish our trade there.

Co-operative Accessory Selling

Bad business of this nature suggests that some co-operative plan of introducing our accessories may be necessary in Buenos Aires and also in Rio de Janeiro. In these two cities we should have large supply houses well stocked with our goods. If the existing houses will not adequately stock our goods but prefer to favor European lines, then it is essential that we take active steps to establish ourselves. It would be wise to consider going so far as several of our accessory concerns not in conflicting lines combining to open one shop in each place for the sale of goods.

By establishing such a house those makers would be assured of proper representation. They could carry adequate stocks of parts, and could have one or more representatives selling the goods through the respective countries.

England has several large department stores in Buenos Aires, in Rio de Janeiro, in Sao Paulo, and other cities. Naturally, these stores push English goods. It is a wise foreign policy to establish such stores. To-day it looks feasible that it might be wise to open a large supply house in Rio and another in Buenos Aires for U. S. A. accessories. It is too expensive for many of our individual makers to open shops for their own line. That would prove impractical. But co-operation can solve the difficulty.

We found quite a few examples of where South American supply houses are buying direct from U. S. A. agents, and in not a single instance did we find any difficulties. The goods invariably came as ordered, they were properly packed, and prices were generally lower than where the goods were bought through a New York exporting house.

Get Close to Market

The main objection to so many of our large concerns selling through exporting houses is that the manufacturers do not get in as close business relationship with the South American retailer as they should. There are many abuses that never reach the ears of the manufacturer. He may note that the sale of his goods is dropping off, but he may never learn the exact reason. By establishing a Buenos Aires representative he will keep in close touch with his market and be in a much better condition to build up an export trade.

To-day a large percentage of the sales of our accessories there are not active sales, but rather orders filled by exporting houses in response to orders from South American houses. It would surprise you to see the line of goods manufactured by some of our largest houses and yet sold through exporting concerns. Such business is not permanent business, and such is not the correct way of building up a foreign business. The business is worth going after, and going after in a businesslike way. We should go after it to-day, otherwise our goods will gain a reputation for higher prices than European lines, due to the added percentages charged by exporting houses for their work. This can be saved by direct business. To-day we cannot afford to get a reputa-

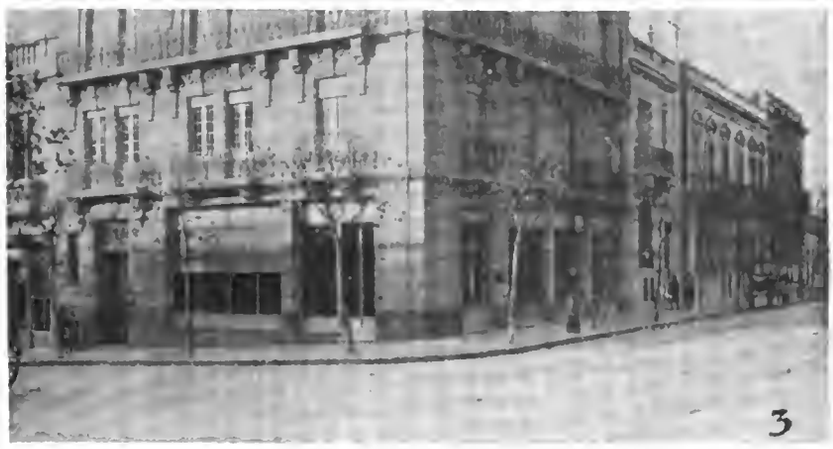
1—*This shows the salesroom of the Ford dealer in Montevideo. There is the usual salesroom with good display windows. Inside you find a very complete line of accessories and spare parts. From this house the whole of Uruguay is controlled*

2—*Here is a typical accessory store in a Brazilian city. The show window in front is well filled, and window dressing is about as well followed out as in U. S. A.*

3—*This is the egency of Cadillac and Chevrolet in Montevideo. It is typical of those large machinery houses that make motor cars a side line. The front windows are not used for car or accessory display. The accessories are generally handled on side shelves, resembling a hardware store*

1—*This is the Ford agency in the City of Sao Paulo, Brazil, from which over 800 Fords have been sold. This agency has a fine show room and in addition has a separate store for spare parts and accessories. Tires of several well known U. S. A. makers are also carried in Ford sizes*

2—*This is the display window of Antonio Prado in Sao Paulo, who carries a stock of accessories worth $50,000 U. S. gold. It is the largest accessory stock in Sao Paulo and a very complete one. Every line of European accessory is carried and many U. S. A. lines, but there are many U. S. A. lines found missing. Senor Prado has found it hard to do business with many U. S. A. firms, which accounts for too few of our goods*



3—*This is the Hudson dealer in Montevideo, Uruguay. It is a typical modern business place. Inside you find show cases filled with accessories. No more modern business place could be found. The store is as clean inside and out as one of our own. Cars are displayed in exactly the same way*

tion for high prices on our goods. Such reputations will live after we lower the prices, and will be sure to work us injury when Europe gets back in the market.

Need Spanish Stenographers

In carrying on business direct with the large supply houses in Buenos Aires, Rio de Janeiro, Sao Paulo, Santiago, Montevideo, and other cities, we must conduct business correspondence in the language of the country. For Brazil, use Portuguese, and for all of the other countries Spanish. You cannot satisfactorily carry on business correspondence in English. There is not any difficulty in securing competent Spanish stenographers in U. S. A., but you will have to pay them more than you pay the average stenographer.

You must get catalogs in Spanish and Portuguese. Do not send catalogues in English, as it only tends to give the impression that you are snatching a little easy business and that you do not intend to stay permanently in the field. You must go into the field for keeps, to stick. That is the greatest business advertisement you can use. South Americans like to see us go there to stay. They will trade much quicker with us when they see us sending our own men, opening adequate quarters, and building for the future.

Make your catalogs simple, much more simple than you would use for the U. S. A. The Latins of South America are not so mechanically inclined as are our people. They are more given to arts, music and sculpture. They like illustrations, and your catalogs should abound with them.

Keep Prices Out

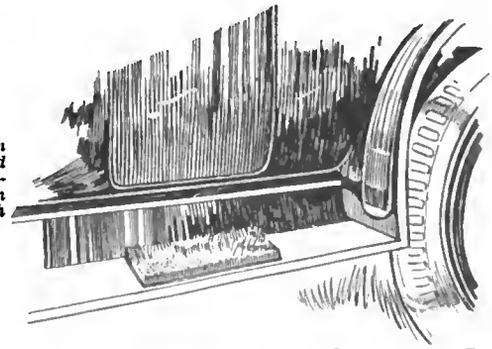
Do not put prices in the catalogs. There are several reasons for it. First, the South American dealer must pay the freight, he must pay the customs, and he must pay marine insurance, and, in these days, war insurance. His selling price must be based on all of these factors, and so, if any U. S. A. maker tries to add prices to his Spanish or Portuguese catalogs for South America or the West Indies, he is only clogging the wheels.

(To Be Continued)

Door-Mat for a Town Car

WHEN the interior of a closed car is fitted up with delicate trimmings and carpets like a lady's boudoir, and many cars are of this nature, it is an advantage to keep dust and mud off the floor, yet anyone stepping into the car from the street cannot help carrying a little dirt on his shoes.

To avoid this an idea which originated in Paris and ought to be popular in the big cities of America is worth mentioning. This is to have a small piece of stout door mat neatly cut and edged and strapped to the running board just below the door opening. The mat can be sewn to metal end pieces and screwed to the running board, or it can be fixed with screws and washers, the heads of the screws being well buried in the mat. As an accessory a device of this sort should sell well. It would need to be of a quality to suit high-grade cars, but need not cost a great deal.



Door mat on running board of finely upholstered town car to catch street dirt

Fascination in Tractor Design

Tractor Engineering 13 Years Behind Automobile—Concentrated Effort Will Overcome This Rapidly—Some Difficult Problems of Wide Scope and Many Minor Easy Ones

By A. Ludlow Clayden

AUTOMOBILE engineers are going to take up the tractor and men trained in the automobile industry are going to make possible 13 years of progress in 5 years or less. They are going to do this largely apart from any business reasons.

They are going to enter the tractor field as individuals because of the immense fascination of the machine. There are many passenger car engineers who have never been able to work up much enthusiasm over the motor truck, probably because the truck is rather like a passenger car shorn of many refinements, but the tractor has a different appeal. The effect of a first sight of a tractor demonstration is indescribable; one feels he is witnessing a manifestation of a new form of energy. It provokes much the same tingling of the blood as does the first sight of a speedway with a bunch of cars tearing past. Probably the explanation is that one sees and realizes in the deep-biting plows and the rapidly changing face of the landscape that same raw *power* which is the fascination of the speedway.

Whatever be the truth the fact remains that any man who took up automobile engineering for the love of the art has only to see a dozen tractors blazing their trail across acres of stubble in order to discover a new enthusiasm.

Development Will be Rapid

Even among tractor engineers it would be difficult to find a man who would contend that the gasoline tractor has reached more than an early stage in its development. To make a comparison with the automobile or motor truck is far from easy, the conditions of service and the requirements being so greatly different, but it is fairly close to the truth if we say that the gasoline tractor to-day is at about the same stage of its development as was the passenger automobile in 1903.

This does not mean that the tractor is going to need another 13 years to reach a stage equal in development to the 1916 automobile. Probably what took 12 years for the passenger car will be done in 5 or fewer for the tractor, general accumulated experience now being so much greater, but the amount which remains to be done will provide sufficient work to give the tractor engineers a very full 5 years.

An automobile engineer in approaching the problems of tractor design must first clear his mind completely of all prejudices. He must manfully resist the natural impulse to compare tractor features with, for instance, motor truck convention. In many ways it would be possible to draw a closer parallel to the motor boat than to any road vehicle. Really, though, the tractor is not comparable with any other self-moving machine. While it is more difficult a problem than the automobile in some ways it is easier in others, but is essentially different. A most successful truck engineer could easily make a very bad tractor if he took on the job with a light heart.

None the less, the automobile is going to benefit by reason of what will be learned in developing the tractor. To give an example, the kerosene carburetor is essential to the tractor, and already experience is being gained which will be valuable throughout the whole range of internal combustion engineering. Another thing which is as yet imperfect for tractors is the ignition system, and a curious little thing which comes to light in this respect is a growing demand from the tractor men for a smaller spark plug, the engineers quoting all the arguments recently advanced by aeroplane engine builders in favor of the metric size of plug shell.

Six Major Problems

Having said that the tractor is as yet only partially developed it may be well to mention the major problems that are yet not overcome:

First: Reliability is not good enough yet, not nearly good enough. This is partly due to poor engineering that can be recognized as such and partly to the peculiarly difficult conditions of a tractor's work.

Second: The efficiency of the machine as a whole can be improved very greatly; must be improved, in fact. At present the horsepower at the drawbar and the horsepower at the flywheel are too widely different.

Third: The weight is usually out of proportion to the horsepower. Weight is an essential in order to permit a sufficient drawbar pull, but it can be applied scientifically so that every ounce tells, or otherwise. Frequently the amount of waste weight is as great as the amount of useful weight.

Fourth: The question of drive is unsolved. We have one-wheel, two-wheel, three-wheel and four-wheel machines, all-caterpillar machines and machines which are combinations of the wheel and the caterpillar. They cannot possibly all be right, yet there is not enough experience today to enable any one system to be named as the best for all purposes.

Fifth: The trouble of rapid turning is important. There are some machines which can turn in their

own length, but to do it they require mechanical features regarded as revolutionary by the more conservative builders. The advantage of a square turn is very great and it must be decided whether this advantage can be given without any drawback.

Sixth: Then there is size. We have now every conceivable size and power from very little to very much. There are too many sizes. The biggest machines will always have a market, but a limited one. The very small machine will also have its uses, but it will have to be decided just what size the great big majority of farmers will find most efficient. This is best stated in terms of drawbar pull and the ideal size for general work is variously estimated at anywhere from 1500 up to 6000 lb. This is a matter for experience mainly, but study can help to solve the problem.

There is no need to itemize further; this will be done in a subsequent article when the different problems will be tackled one by one at greater length.

Torque and Ratio Determine Drawbar Pull

Fallacy of the Horsepower Rating Self-Evident When Its Variation With Speed Is Taken Into Consideration

THE belief is being rapidly accepted that the most logical method for rating tractors is by the drawbar pull rather than by the horsepower characteristics of the engine. If a rating of this nature is to be made it is necessary that some allowance be made for the nature of the soil through which the plow is to be pulled in order that the soil resistance factor may be taken into account.

To make such checking easy, the Hyatt Roller Bearing Co. has invented a hydrostatic instrument which can be placed between the tractor and the plow, and the gage mounted upon it registers the actual force of the pull which the tractor is exerting. In addition to the pressure gage there is a recording device which registers variations in the pull.

It has been pointed out that tractors working within a few yards of each other will show great differences in performance, although the horsepower ratings of the engines will be the same. One tractor may be pulling three plows and the other four and yet the ratings by horsepower will be equal. Of course, where the difference comes in is in the tractive speed. The actual work involves all the factors of pull, distance and time. It is impossible to get a performance figure unless all of these are included in the calculations.

With an instrument of the nature mentioned, the objectionable guess work rating is avoided. It is quite customary among farmers to make a rough guess at the performance rating of a tractor by stating that it is capable of pulling so many plows under average soil conditions. This is at the best only a rough approximation as the tractive pull necessary to carry a plow through different kinds of soil is subject to the widest possible variation. Even in the same kinds of soil the pull required will vary with conditions.

It must be remembered that the torque of the gasoline engine is fairly constant through a wide range of motor speeds. With the torque constant the horsepower output will naturally bear a practically constant ratio to the speed or r.p.m. Pulling ability is determined fully by engine torque and gear ratio. It does not require a mathematician to see that if the torque is constant, and the gear ratio is constant, the pulling power of the tractor is going to be constant also for a wide range of speeds. The horsepower curve will be going up as the speed increases, however, and thus the fallacy of a tractor rating by horsepower is self-evident.

Coming to a practical rating by pull alone, the question at once arises as to how to secure a standard condition in order to make a rating. It is for a purpose of this kind that the hydrostatic instrument should be available. It has been suggested that the tests be carried out on a hard, dragged dirt road, and this really seems a practical manner of getting at the much-mooted question.

Power of Martin Engine

LEE N. GRIFFITH, the engineer responsible for the Martin-Griffith aviation engine described in THE AUTOMOBILE for Aug. 10, has written stating that the maximum power of the engine does not occur at 1326 r.p.m. but at about 2000 r.p.m. The official tests made at Washington was performed with a propeller and not a dynamometer.

Hyatt hydrostatic instrument for measuring pull mounted on a tractor under actual service conditions

Welfare Department a Factory Necessity

Sociological Work Is Not a Matter of Philanthropy But Results in Pure Gain to both Employer and Employee—Examples in Cadillac Plant in which their Work Is Under Well-Defined Jurisdiction

WORKMEN, performing their labor under advantageous conditions of heaolth and mental well-being, give a better return for their wages than those who work under the opposite conditions. In a nutshell, this gives the entire selfish side of the factory welfare question. Taken as a matter of dollars and cents, of return for a given investment, a happy workman, and that means a healthy one, is a better paying proposition than one who is under the disadvantage of mental strain or ill health.

Sunshine, open air, sanitary conditions and freedom from accidents are the basic necessities for a high health rate among the employees of a factory. Men who are paying frequent visits to the hospital, or who are staying home on sick leave are a loss to themselves and the concerns which employ them. They are not happy, their thoughts are distracted by their own personalities and instead of the mind being on their work it is upon their own physical condition. In each individual workman in which this condition exists, there lies a loss for the concern that employs him. More important still from the human standpoint, there is a man who is not happy in his work and is therefore incapable of doing himself justice, no matter how he may try.

Output Versus Outlay

The automobile industry, in its mushroom-like growth has been compelled to expand in a very disadvantageous way, in a great many instances. More space to carry out greater production schedules has been demanded and the result is that there has often been no time to stop for the best possible layout of factory as regards the human welfare standpoint. Competition has been so keen that factories could not afford to lose time while adding more space and consequently the growth in the factory has led to results which compare with some of our older cities.

Where a city has been laid out new, in a new part of the country, the streets are broad and regular. They run parallel to one another and are intersected at right angles by other streets. The houses are spaced regularly, the streets are clear and the sunshine has a chance to filter through. Old cities which have grown so fast that they have been unable to follow any well laid-out plan of development have crooked, winding streets that follow the old Indian trails. They are compelled to stick to the old methods because they are unable to grow and to change at the same time. So it is also in the automobile factory—to keep up with the march of progress it has had to grow, to keep up with the new ideals in manufacturing welfare it ought likewise to change.

The automobile industry is only now beginning to find itself. There have been factories advantageously located that have been able to adopt the new methods while developing, there are a great many others that are adding space at the present time and in this new space they are taking care that the welfare angle is given all possible attention.

In the past few years, we have heard much about the sociological side of a manufacturing plant. It has shown itself in direct and indirect ways. An example of the direct way is where the manufacturer has declared profit-sharing or bonus schemes that put cash directly into the pockets of the workmen. In the indirect way, the money has been spent by the factory in supplying more sunshine, more air, better conditions and often better food. The hygienic side of the factory worker's life is being looked into. In many cases even his family life has been made the subject of study by a special part of the employers' organization that is fitted to take care of this delicate work in a way that is suitable to a democracy.

Not Philanthropy

It is not a question of philanthropy. If it were, the employee would be the only one to benefit. On the other hand, it is not wholly and purely economic, because the expert accountants cannot render even at the end of a stated period an exact statement as to the money saved or made through the establishment of the new methods. But it does represent a saving,—a saving to industry, a saving to the individual and also a saving to the family, in that it means fewer hours of unemployment due to illness or accident.

Taking the Cadillac company as an example of what has been accomplished, some very interesting things can be learned. It was in 1910 that this concern first established an organized welfare department. Before that time there were various unorganized schemes of assisting workmen who suffered from various combinations of adverse circumstances, but a close study of the question showed the officers of the concern that the men were not securing the maximum return even from the fitful efforts that were then made.

One of the lunch rooms in the Cadillac factory where pure food, well-cooked, is served

View of the lunch room at the main plant, showing menu board, coffee, pie, fruit and sandwich counters

All these different branches of activity naturally fell under the one head of sociology. It did not mean by any means that the Cadillac company was forced to philanthropical work among its employees, but it did mean that in order to see that the men and women in the employ of the company were getting the best possible nourishment and were kept in the best possible health that food supplied at actual cost, without loss to the company, well cooked, and above all clean, should be furnished.

If the number of factories having large bodies of workmen employed are considered it will readily be seen that few of them are surrounded by restaurants that supply good food at moderate prices.

The food question is not the only one which was taken up under the Cadillac organization. The prevention of accidents, prevention of fire, sanitation, accident relief, benefit society, legal aid and accident claim were also considered and made divisions of the department as well as that of lunch counter and restaurant.

A Safety Engineer in Charge

The way this is worked out is quite simple. A safety engineer is in charge of the accident division, who, with two assistants, is directly responsible for cutting down accidents about the factory. Not only does he investigate existing safeguards, but designs others which are placed upon the apparatus about the plant. Failure on the part of workmen to observe the rules of this official and his staff will bring dismissal and there is no appeal.

A fire marshal who is an experienced man, being a retired captain of the city fire department, is in charge of fire prevention. His duties are quite similar to those of the safety engineer, except that he is in direct charge of all means of preventing conflagrations. He is the court of final appeal in all fire matters as the safety engineer is the court of last appeal in accident-prevention matters.

Saves $9,500,000 in Eyes

There is an emergency hospital always ready and always fully equipped. A chief surgeon is in constant charge of the hospital. His assistants form the remainder of a committee which looks after the medical and surgical end of factory matters in the same way as the accident and the fire committees look after theirs. Eye operations, etc., can readily be taken care of. In a single year there were 37,757 dispensary cases handled here, 4300 cases of grippe in one winter, 6250 cases of headache, 800 cases of toothache and 437 cases of injury in which disability of more than one day was caused. Over 40,000 abrasions of a small nature were taken care of and more than 9000 cases of foreign bodies in eyes. Under the Workmen's Compensation Act, these eyes have a valuation alone of from $3,500,000 to $9,500,000. The men are encouraged to take all their ills to the doctor's office, no matter how small they may be.

$35,000 in Sick Benefits

The Mutual Aid or Benefit Society paid in the first 3 years of its existence $35,000 in sick accident and death benefits. A payment of 10 cents per week is exacted from each workman to take care of this fund. In the restaurant and kitchen work, a steward is in general charge. It started with stew being served at 6 cents a cup to the men. This proved to be so popular that a universal restaurant service was demanded with the result that an employee of the company can purchase an ordinarily 5-cent article of food for 3 4/7 cents. Milk is sold at the same figure per pint, and during a single year 456,000 pints of milk were distributed among the employees. The gross business of the restaurant division of the welfare committee is about $50,000 a year and the cost to the company is practically nil. It is self-supporting and yet of untold value to the mental and physical condition of the men—and must bear its reflection in the quality of the work of the individual.

Constant Pressure Efficiency 25 Per Cent Lower

Cannot Compare in Theoretical Efficiency with Constant Volume or Otto Cycle According to Napier—Mathematical Comparison of the Two Working Cycles

THE efficiency of the constant pressure cycle may be all the way from 25 to 60 per cent less than that of the constant volume or Otto cycle according to James Langmuir Napier who has just published in *The Automobile Engineer* a criticism of the paper on the constant pressure cycle read by Messrs. A. B. Brown and Herbert Chase before the summer meeting of the Society of Automobile Engineers.

In his criticism Mr. Napier makes a particular point of the fact that the authors, Messrs. Brown and Chase, state that they have purposely avoided the use of formulas having to do with the thermo-dynamics of the constant pressure cycle. He goes on to say:

"Neglect of elementary principles is always unsafe, and in this case peculiarly disastrous for the reason that the author's enthusiastic advocacy of the constant pressure cycle is confessedly founded upon a quasi-scientific statement, attributed to one R. M. Neilson, and promulgated by Henry D. Suplee, to the effect that with a compression pressure of only 30 lb. absolute (approximately 15 lb. gage) a constant pressure engine has an ideal efficiency of 84 per cent.

"This statement is so far from being true that it appears desirable to set forth exactly the results which might be anticipated from a constant pressure engine under 'ideal' conditions, understanding, of course, that while such conditions are impossible they constitute an easy but rough ground of comparison between engines in which combustion takes place at constant volume and constant pressure respectively.

"The basic diagram in respect of a constant pressure engine is indicated in Fig. 1. At the point C the gas is assumed to occupy n volumes at atmospheric temperature and pressure, both expressed in absolute units. Compression reduces the gas to one volume at the point A, and heat is added at constant pressure between A and B, which latter point is here assumed to be the end of the stroke. The equation to the curves BD and ACE is $PV^{1.4} = \text{Const.}$, and these curves are supposed to extend infinitely. Under these conditions the heat added during the cycle is represented graphically in PV units by the area $ABDEC$, and the work done during the stroke by the area ABC. The principal pressures and temperatures are:

Pressure at $C = 14.7 = p$
" " $A = pn^{1.4} = P$
Temperature at $C = T = 290°$ abs. Cent.
" " $A = Tn^{.4}$
" " $B = Tn^{1.4}$

These quantities are calculated in Table I. for values of n up to 10.

TABLE I

n	$pn^{1.4}$	$Tn^{.4}$	$Tn^{1.4}$
2	38.79	383	765
3	68.42	450	1,350
4	102.30	505	2,019
5	139.90	552	2,761
6	180.60	580	3,482
7	224.10	632	4,421
8	270.20	666	5,330
9	318.50	698	6,285
10	369.30	728	7,285

In Fig. 1, area $ABDEC$

$$= P(n-1) + 2.5\,Pn - 2.5\,P$$
$$= 3.5\,P(n-1) \quad \ldots \quad (1)$$

And area $ABC = P(n-1)$

$$- 2.5\,P\left(1 - \frac{1}{n^{.4}}\right) \ldots \quad (2)$$

Therefore, when combustion at constant pressure is continued to the end of the stroke, the thermal efficiency of the cycle is represented by:

$$\frac{P(n-1) - 2.5\,P\left(1 - \frac{1}{n^{.4}}\right)}{3.5\,P(n-1)}$$
$$= \frac{1}{3.5} - \frac{\left(1 - \frac{1}{n^{.4}}\right)}{1.4\,(n-1)} \quad \ldots \quad \ldots \quad (3)$$

"Values of this quantity are given in Table II., where they are compared with values of $\left(1 - \frac{1}{n^{.4}}\right)$, which represents for any value of n the thermal efficiency of the cycle, which includes combustion at constant volume. In the meanwhile it may be noted that the quantity (3) has a maximum value, for when n is infinite its limit is $\frac{1}{3.5} = .2857$, and therefore, under the assumed conditions, the ideal efficiency of the constant pressure cycle cannot exceed 28.57 per cent.

Following the analogy of the steam engine, improved economy may be looked for in an early cut off, as indicated in Fig. 2, where the point B, at which addition of heat ceases, is located so that the gas has expanded only to m volumes, m being some quantity less than n. Then, the pressures at A and C being equal to those of Fig. 1, we have:

Temperature at $C = T = 290°$ abs. Cent.
" " $A = Tn^{.4}$
" " $B = Tmn^{.4}$

Also:

Area $ABDEFC$
$$= P(m-1) + 2.5\,Pm - 2.5\,P$$
$$= 3.5\,P(m-1)$$

And area $ABDC = P(m-1)$

$$+ 2.5\,Pm\left(1 - \left(\frac{m}{n}\right)^{.4}\right) - 2.5\left(1 - \frac{1}{n^{.4}}\right)$$

Therefore:

Efficiency =

$$\frac{(m-1) + 2.5\,m\left(1 - \left(\frac{m}{n}\right)^{.4}\right) - 2.5\left(1 - \frac{1}{n^{.4}}\right)}{3.5\,(m-1)}$$
$$\ldots \quad \ldots \quad \ldots \quad (4)$$

$$= \frac{1}{3.5} + \frac{m\left(1 - \left(\frac{m}{n}\right)^{.4}\right) - \left(1 - \frac{1}{n^{.4}}\right)}{1.4\,(m-1)}$$
$$\ldots \quad \ldots \quad \ldots \quad (5)$$

"Here m has two limits, 1 and n, and obviously when

$m = n$ the value of the expression (5) is the same as that of (3). If we assume the other limit and put $m = 1$ in Eq. (4). we arrive at the indeterminate fraction $\frac{0}{0}$, which may be evaluated in the ordinary way by differentiating both numerator and denominator and again substituting 1 for m.

Collecting the terms containing m in Eq. (4), we have

$$\frac{3.5\ m - \frac{2.5\ m^{1.4}}{n^{.4}}}{3.5\ m}$$

differentiating:

$$\frac{3.5 - \frac{3.5\ m^{.4}}{n^{.4}}}{3.5}$$

and, putting 1 for m,

$$\text{Efficiency} = \left(1 - \frac{1}{n^{.4}}\right)$$

which, as might have been anticipated, is the efficiency at constant volume combustion. The efficiency of a constant pressure engine under the conditions of Fig. 2 is therefore improved by early cutoff, but only attains (for equal values of n) the efficiency of a constant volume engine when the power evolved falls to zero. For purposes of comparison the theoretical efficiencies are calculated for a constant pressure engine, assuming that addition of heat ceases at half-stroke; that is, when $m = \frac{n+1}{2}$, or $m - 1 = \frac{n-1}{2}$ These figures are embodied in Table II., which exhibits, therefore, the relative efficiencies at different values of n of (a) constant volume combustion, and (b) constant pressure combustion under the conditions shown by Figs. 1 and 2, the addition of heat ceasing at half-stroke in the latter case.

TABLE II

	Thermal Efficiencies Per Cent		
		Constant Pressure Engine	
n	Constant Volume Engine	Heat to End of Stroke	Heat to Half-stroke
2	24.22	11.27	17.26
3	35.55	15.87	24.55
4	42.56	18.44	28.70
5	47.47	20.09	31.41
6	51.17	21.26	33.34
7	54.08	22.13	34.78
8	56.47	22.81	35.94
9	58.47	23.35	36.83
10	60.19	23.79	37.57

"These are not the ultimate ideal efficiencies for either cycle, but before proceeding further in search of Mr. Neilson's 84 per cent it will be well to pay some attention to conditions of temperature, in which connection the first obvious consideration is the mode of addition of heat, a matter which is not taken into account in the diagrams Figs. 1 and 2.

"Since we are dealing with ideal conditions we may imagine that in a constant pressure engine heat is added from a source of varying temperature, so that the temperature of the charge increases in proportion to the volume, and under these conditions the mean temperature in the cylinder during addition of heat will be the mean of $Tn^{.4}$ and $Tn^{1.4}$, or the mean of $Tn^{.4}$ and $Tmn^{.4}$, according as the conditions are those of Fig. 1 or Fig. 2. Addition of heat in this manner can, however, scarcely be considered practicable, since each particle of

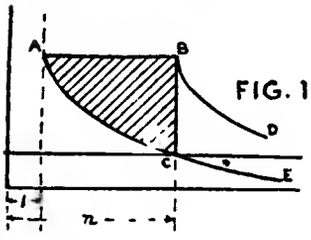

FIG. 1

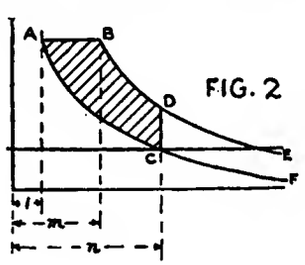

FIG. 2

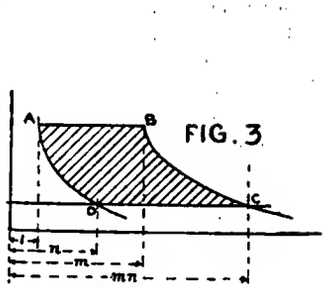

FIG. 3

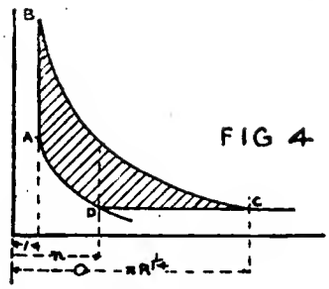

FIG 4

charge entering the cylinder is assumed to carry with it its own supply of combustible, and we must, therefore, consider alternatively that the temperature in the cylinder during addition of heat is constant, and is $Tn^{1.4}$ or $Tmn^{.4}$, as above. This condition is described in Tables III. and IV. as 'practical'; that is, relatively practical as compared with the 'ideal' assumption of a source of heat of varying temperature.

"In comparing the mean temperatures during the working stroke in constant volume and constant pressure engines, it may be found under certain circumstances that for the same consumption the mean temperature of the constant volume engine is the higher. But its power for the same consumption will also be higher, and I have therefore introduced in Tables III. and IV. a column showing the mean temperature at constant volume combustion when the powers are equal. This necessitates the assumption of a lower temperature of explosion at equal powers than at equal consumption, and this assumption is made throughout these two tables, the heating value of the charge being taken as proportional to the value of n. It will be understood, of course, that the tables are merely illustrative.

"In adiabatic expansion the mean temperature during expansion to n volume is:

$$\frac{\int_n^1 CV^{-.4}dV}{V-1} = \frac{C(n^{.4}-1)}{.6(n-1)} \qquad \ldots \quad (6)$$

which expression is used in calculating the mean temperature during expansion in the constant volume engine, and also in the latter half of the stroke in the constant pressure engine illustrated by Fig. 2; noting in the latter case that the n of Eq. (6) becomes $\frac{n}{m}$, the expansion ratio, and C becomes Cm.

In Fig. 1 the increase of temperature between A and B is $Tn^{.4}\ (n-1)$, therefore on combustion of the same charge at constant volume the increase of temperature would be $1.4\ Tn^{.4}\ (n-1)$, and the temperature of explosion would be $Tn^{.4}\ (1.4\ n - .4)$. The temperature of explosion in the case of equal powers is, therefore,

$$Tn^{.4}\left\{1.4\ (n-1)\left(\frac{\text{efficiency at const. press.}}{\text{efficiency at const. vol.}}\right) + 1\right\}$$

a similar calculation being made in the case of Fig. 2.

TABLE III

Mean temperatures during working stroke, when heat is added in constant pressure engine throughout stroke.

	Constant Volume		Constant Pressure	
n	Equal Consumption	Equal Powers	Ideal	Practical
2	890	544	574	765
3	1,330	787	900	1,350
4	1,892	1,027	1,262	2,019
5	2,452	1,203	1,656	2,761

TABLE IV

Mean temperatures—addition of heat ceasing at half stroke.

	Constant Volume		Constant Pressure	
n	Equal Consumption	Equal Powers	Ideal	Practical
2	559	493	503	551
3	840	688	751	864
4	1,128	880	1,012	1,202
5	1,422	1,022	1,294	1,570

The comparison between the constant pressure engine and one operating on the Otto cycle should properly cease at this

point, but our authors claim additional economy by the process of expanding the products of combustion down to atmospheric pressure. This operation is by no means wholly impossible, and has, in point of fact, been carried out in a modified form by Atkinson and a few others, and precisely with the additional economy which might have been anticipated. The system in its complete form involves the use of cylinders much too large for automobile work, but it is theoretically interesting, and it is here, if anywhere, that a sanguine investigator might hope to re-discover Mr. Neilson's marvel.

"Fig. 3 represents the final possibilities of the constant pressure engine. The volume of the charge is n, which as before, becomes one volume at A, and has then a temperature of $Tn^{.4}$ and a pressure of $pn^{1.4}$. By addition of heat this volume becomes m volumes at the point B, the value of m being such that $m = \frac{C}{Tn^{.4}} + 1$, where C is a constant representing the heating value of the mixture. For present purposes I assume $m = 1{,}428$, which represents a mixture capable of adding 2,000 deg. C. on explosion at constant volume. This value is adhered to throughout what follows.

From B the products of combustion are assumed to expand to atmospheric pressure at the point C, where they have the volume mn. The atmospheric line completes the power diagram.

In this diagram the area $ABCD$ is equal to:

$$P\ (m-1) + 2.5\ Pm\left(1 - \frac{1}{n^{.4}}\right) - 2.5\ P\left(1 - \frac{1}{n^{.4}}\right) - \frac{P}{n^{.4}}\ (m-1) = 3.5\ P\ (m-1)\left(1 - \frac{1}{n^{.4}}\right)$$

and, since the heat added is, as shown in connection with Fig. 2, $3.5\ P\ (m-1)$, we have

$$\text{Efficiency} = \frac{3.5\ P\ (m-1)\left(1 - \frac{1}{n^{.4}}\right)}{3.5\ P\ (m-1)} = \left(1 - \frac{1}{n^{.4}}\right)$$

which is precisely the efficiency of the ordinary Otto cycle with expansion only to n volumes, as given in the first column of Table II.

"Table V. exhibits some of the principal figures relating to Fig. 3, and includes for comparison the mean temperature during the working stroke of an engine on the Otto cycle expanding to n volumes only.

"As already indicated, it cannot be admitted that the constant pressure engine has any monopoly in the matter of expansion to atmospheric pressure. The arrangement is equally practicable, or equally impracticable, as you choose to consider it, in the case of the engine where combustion takes place at constant volume. Fig. 4 relates to such an engine using a mixture of the same heating value as that of Fig. 3, and, in this case, if we put $\left(\frac{2{,}000}{Tn^{.4}} + 1\right) = R$, the expansion curve coincides with the atmospheric line at $nR^{\frac{1}{1.4}}$ volumes.

TABLE V

Constant pressure engine—expanding to atmosphere

n	m	Volume Swept by Piston	Maximum Pressure	Maximum Temperature	Mean Temperature	Mean Temp. Otto to n Vols.	Efficiency
2	4.73	8.46	38.79	1,811	1,669	2,049	24.22%
3	4.17	11.51	68.42	1,878	1,575	1,905	35.55%
4	3.83	14.32	102.30	1,933	1,502	1,807	42.56%
5	3.59	16.95	139.90	1,980	1,439	1,729	47.47%

"The efficiency of such an engine is represented by the fraction:

$$\frac{2.5\ PR\left(1 - \frac{1}{n^{.4}R_{\frac{1}{n}}}\right) - 2.5\ P\left(1 - \frac{1}{n^{.4}}\right) - pn\ (R^{\frac{1}{1.4}} - 1)}{2.5\ P\ (R-1)}$$

$$= \frac{R\left(1 - \frac{1}{n^{.4}R_{\frac{1}{n}}}\right) - \left(1 - \frac{1}{n^{.4}}\right) - \frac{.4}{n^{.4}}\left(R^{\frac{1}{1.4}} - 1\right)}{(R-1)}$$

$$= 1 - \frac{1.4\ (R^{\frac{1}{1.4}} - 1)}{n^{.4}\ (R-1)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

"Temperature are calculated by the methods already used. Results similar to those of Table V. are embodied in the following table:

TABLE VI

Otto cycle—with additional expansion to atmosphere

n	R	Volume Swept by Piston	Maximum Pressure	Maximum Temperature	Mean Temperature	Efficiency
2	6.222	6.38	241.3	2,383	1,442	45.34%
3	5.444	9.07	372.5	2,450	1,349	52.22%
4	4.960	11.49	507.4	2,505	1.295	56.65%
5	4.623	13.92	646.9	2,552	1,241	59.70%

"For further convenience of comparison these figures are arranged in Table VII. so as to indicate more conveniently the relative temperatures, pressures, and cylinder dimensions in (a) the ordinary Otto cycle with expansion to n volumes, (b) the Otto cycle with additional expansion to $nR^{\frac{1}{1.4}}$ volumes, and (c) the constant pressure cycle with expansion to mn volumes. The value of n is taken at the convenient figure of 4 in each case, and as a mixture of the same heating value is assumed in each case, the powers will be directly proportional to the efficiencies. It will, I think, be admitted that the figures do not support the somewhat peculiarly sanguine conclusion of Messrs. Browne and Chase.

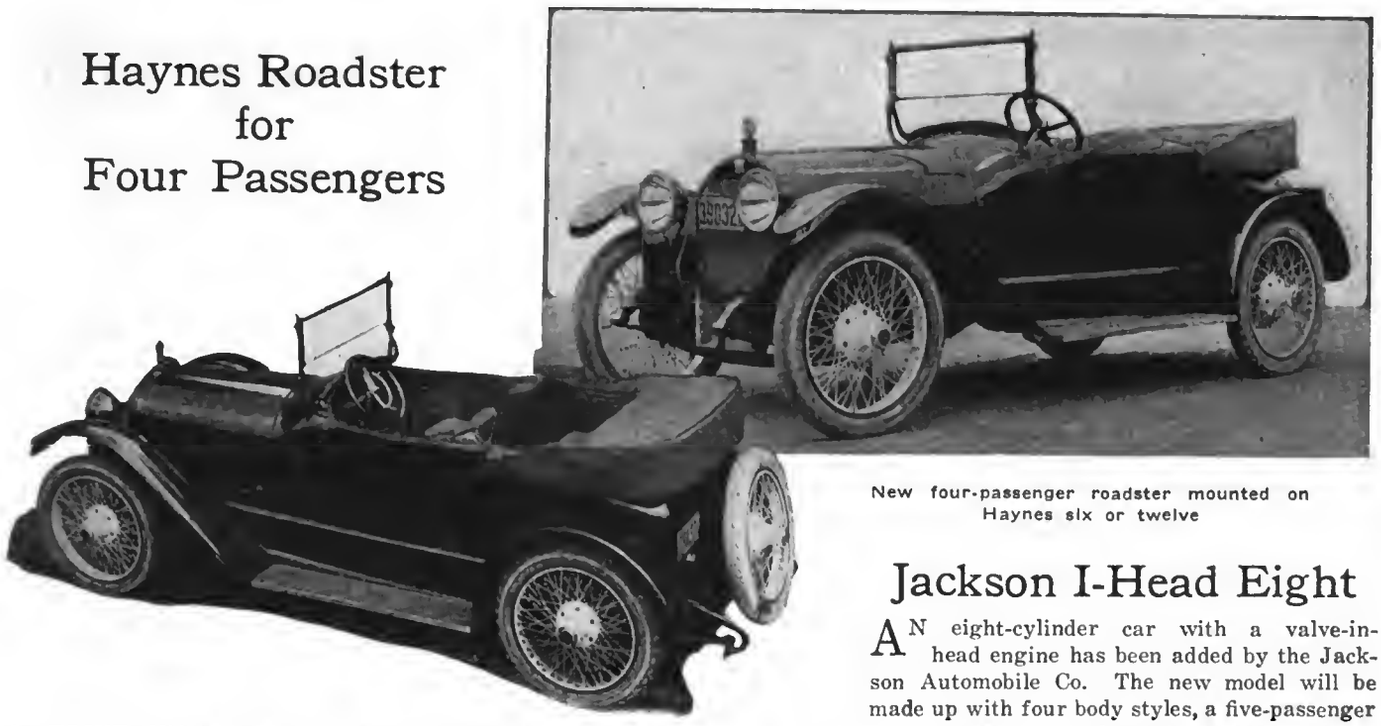
TABLE VII

	(a) Ordinary Otto	(b) Expanded Otto	(c) Constant Pressure
Volume swept by piston	3.00	11.49	14.32
Maximum temperature	2,505	2,505	1,933
Mean temperature	1,807	1,295	1,502
Maximum pressure	507.40	507.40	102.30
Efficiency, per cent	42.56	56.65	42.56

"The first point obvious here is the enormous cylinders required by the constant pressure engine. Without any gain in power or economy over the ordinary Otto cycle engine the volume would have to be increased from 3000 c.c. to 14,320 c.c. This appears prohibitive, but even if large cylinders were admissable for the sake of economy the choice would certainly lie with the expanded Otto, which, with a volume of 11,490 c.c., would, on the same consumption, give power in the proportion of 56.65 to 42.56 provided by the constant pressure engine, and with a lower mean temperature.

"The constant pressure engine apparently scores in the matter of maximum pressure, but the advantage is to a large extent merely apparent, for it is unlikely that two cylinders of 3.00 and 14.32 volumes respectively would be designed with the same bore. It will also be noted that the vaunted flexibility of the constant pressure engine exists only in the imagination of its advocates; the methods available for altering its power output are simply those used in a constant volume engine with a fixed spark; that is, altering the quantity and the quality of the mixture."

Haynes Roadster for Four Passengers



New four-passenger roadster mounted on Haynes six or twelve

DELIVERIES have been going on since early in August on a new four-passenger Haynes roadster which is mounted on either the twelve or six chassis. The new car is a successor to the Haynes three-passenger So-Sha-Belle model, and although it has a greater capacity, it resembles the former model to a great extent in body lines.

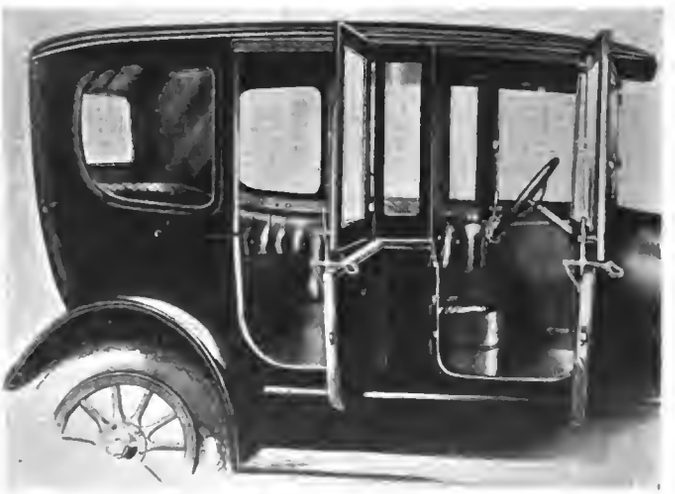
The front seats of the four-passenger roadster are divided and the aisleway between them affords easy passage to the tonneau. The rear seat is wide enough for two passengers, and, when circumstances require, it will accommodate three persons. The rear passengers are given an extra amount of leg room by sloping the backs of the front seats downward toward the brake and clutch pedals. The seats and the sides of the tonneau are upholstered in hand-buffed leather which in turn is covered by gray water-proof seat covers of soft cloth. The body is low and the running boards have a ground clearance of 10 in.

Special attention has been given the comfort of the driver in that the pedal pads may be brought to the desired position and the seat moved forward or backward. By grouping all the cowl instruments on a compact board the controls are moved up within easy reach. The 18-in. steering wheel is heavily notched and highly polished, so that it has an easy grip and good leverage. The accelerator pedal requires a minimum amount of effort, as it moves in a vertical direction and no vibration is transmitted to the arms of the driver since the steering column is mounted in the cowl apron.

Jackson I-Head Eight

AN eight-cylinder car with a valve-in-head engine has been added by the Jackson Automobile Co. The new model will be made up with four body styles, a five-passenger touring and a two-passenger roadster at $1,295, a four-passenger body with divided front seats and sloping rear deck at $1,395 and a seven-passenger touring at $1,370. The two eights and the four, which are now on the market, will be continued without change.

The only difference between this car and other Jacksons is in the power plant as the specifications of the new model include all the features of the others, such as full elliptic springs front and rear. It is stated that the new engine will develop 48 hp. It has a bore of 3 and a stroke of 3½ in. and is fitted with a Zenith duplex carbureter, Stewart vacuum feed, Auto-Lite starting and lighting, Remy ignition, 34 by 4 in. tires and has a 118-in. wheelbase. One of the bodies mounted on the new model is illustrated below.



Body suitable for town or country use mounted on the eight-cylinder, valve-in-head Jackson just added to the line. The two eights and the four previously manufactured will be continued

Hackett Body Is of Striking Design

Straight-Line Effect Characterizes New Four-Cylinder Touring Car—3¾ by 4¼-In. Engine—A Three-Passenger Roadster, a Cabriolet and a Demountable Top

A FOUR-CYLINDER, five-passenger car at $888, with distinctive straight-line body and low, comfortable seats, is the initial offering of the new Hackett Motor Car Co., Jackson, Mich., formerly the Argo Motor Co.

The body design is original, a straight line running from the top corners of the radiator all the way back. The effect is accentuated by the use of a narrow deck extending all around the rim of the body, and also forming the double cowl on the back of the front seat. The straight-line idea is still further emphasized by the fact that the seats are low. The windshield is tilted and there are large louvres in the hood at the same angle.

A Three-Passenger Roadster

In addition there will be a runabout, at the same price, seating three, with the driver's seat slightly ahead of the other two, a cabriolet for about $1,000 and a winter top for the five-passenger at $110 additional.

The chassis is standard with a unit power plant consisting of a 37-hp. engine, G. B. & S. clutch, Grant-Lees gearbox and Walker-Weiss axles.

Detachable Cylinder Head

The engine is a detachable L-head design with cylinders in block and crankcase in two pieces, the lower part being made of pressed steel and acting as an oil pan. Bore and stroke are 3¾ by 4¼ in., giving a formula rating of 22.5, and a piston displacement of 188.2 cu. in. It gives this rating at a piston speed of 935 ft. per min., instead of 1000, and produces its maximum of 36.9 hp. at 2000 r.p.m.

The crankshaft is 35 to 45 point carbon steel, drop-forged and heat-treated, and has three main bearings. The front bearing is 1½ by 3⅞ in., the center, 1⅝ by 2¼ in., and the rear, 1½ by 2 in. Connecting-rod bearings are 1½ by 2 in. Bearings are babbitt, reinforced with perforated steel shells.

Force Feed and Splash Oiling

Lubrication is by combined force feed and splash. Oil is drawn from the reservoir by a plunger pump which is operated by No. 4 exhaust cam, passes through a sight feed on the cowl and from thence to the three main bearings. The overflow from the bearings makes its way to the splash troughs into which the connecting-rods dip. The oiling system is extremely accessible, as the pump and all the piping are on the exterior of the engine.

Valve Adjustments on Stems

The valves are unusual in that the adjusting nuts are on the stems instead of the push rods, and consequently act as spring retainers. The end of the stem is threaded and on it is placed a thimble nut which is held solid by a lock nut. The valves consist of cast iron heads welded on ⅝-in. carbon steel stems. The lift is 7/32 and the clear opening 1⅝ in. The valve stem guides are bushed with 3 3/16 cast iron sleeves.

Camshaft and Disco motor-generator drive are by silent chains, adjustment of the latter chain being accomplished by rocking the bracket on which the unit is carried.

Ignition is furnished by a Remy coil and distributer, mounted at the front and driven off the camshaft.

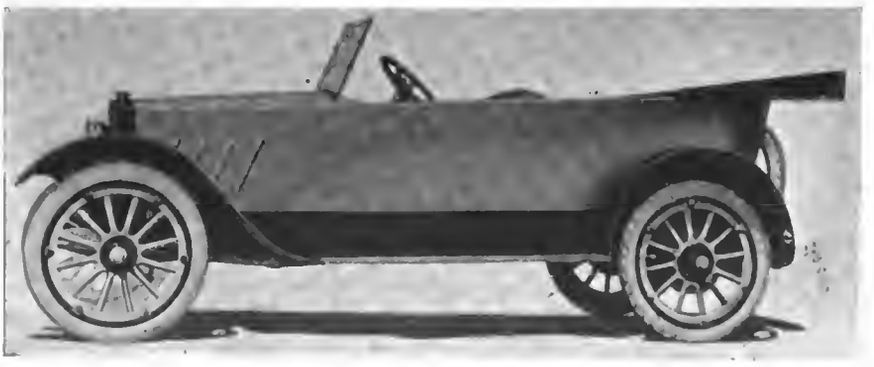
Stewart Vacuum Fuel Feed

The fuel system consists of a tank at the rear from which gasoline is drawn by a Stewart vacuum system to the carbureter, which is a Justrite, a single jet design in which the correct proportion of air and gasoline is obtained by varying the size of the venturi passage.

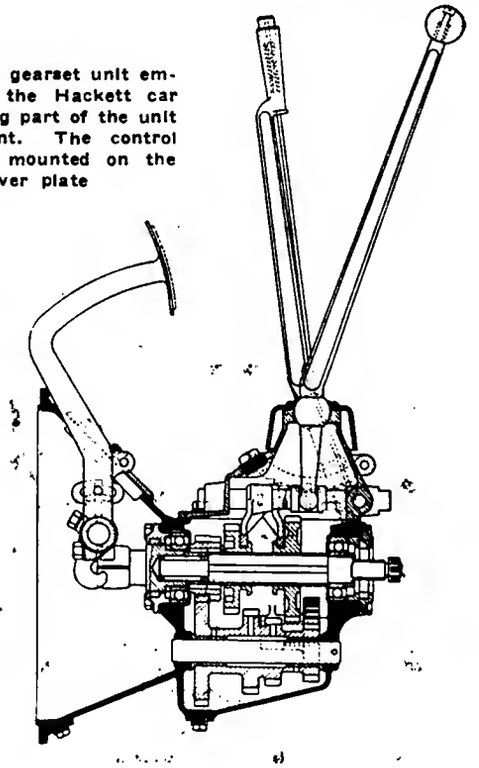
Cooling is by thermo-syphon, a cellular radiator and a four-blade fan being used with it.

Clutch Runs in Oil

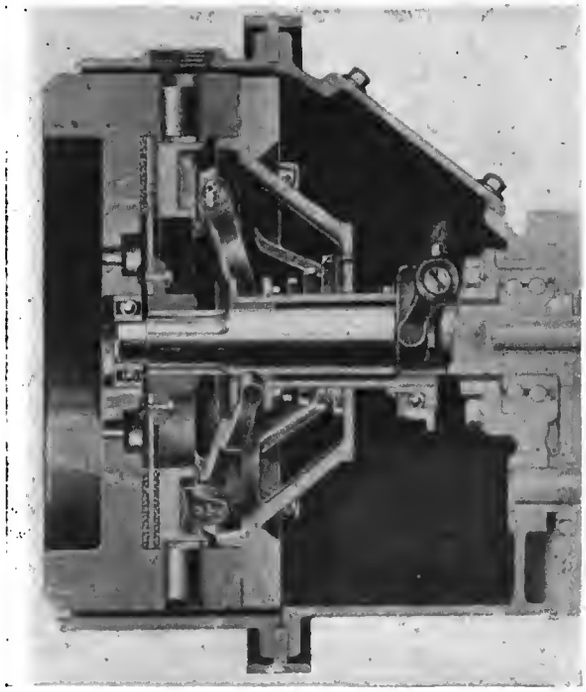
The G. B. & S. clutch is housed in the flywheel and has a single driven disk of steel. A ring of wire-woven asbestos



Straight-line car manufactured by the Hackett Motor Car Co., Jackson, Mich., selling for $888. This is fitted with a winter top for $110 additional. This car and the three-passenger roadster are mounted on a 112-in. wheelbase chassis



Grant-Lees gearset unit employed on the Hackett car and forming part of the unit power plant. The control levers are mounted on the cover plate



Section through the clutch unit on the Hackett car, showing yoke and spring mounting

fabric bears against either face. Smooth action and reduced wear are obtained by running the clutch in oil. It is so designed that no adjustment is required.

The gearbox gives three speeds forward. The gears are 3½ per cent nickel steel. The main shaft is carried on annular ball bearings and the countershaft gears are in one piece, are bushed and are free to rotate on the stationary shaft.

The clutch and gearset are accessible and may be removed quickly and easily without disturbing the engine, which is supported at the rear by arms attached to the flywheel housing. The gearbox bolts to the bell housing.

Semi-Floating Axle

The rear axle is a semi-floating Walker-Weiss with chrome-nickel driving shafts, open hearth ring gear and 3½ per cent nickel pinion. There are two sets of brakes operating on the one set of drums. The front axle is an I-beam design, and steering is by worm and gear. Half-elliptic springs are used in front, 36 by 1¾ and three-quarter elliptic in the rear, 48 by 1¾ in. Wheelbase is 112 in., and the Ajax tires are 32 by 3½, with demountable rims.

The car will be finished in Packard blue with ivory white wheels, and the upholstery will be French pleated.

Control pedals and levers are conveniently placed and the steering wheel is 17 in. in diameter. Cowlboard equipment is complete, including speedometer, oil gage, gasoline choke lever, lighting switches, ammeter and instrument light with metal trimmings heavily nickeled.

Landau-Farr Lubricating Bolt Now on the Market

DAVID LANDAU and H. G. Farr, well known in the automobile trade as spring engineer and chief engineer of the Knox company respectively, have combined their experience in the production of an automatic lubricating bolt. This is to be marketed by the Brown company, Syracuse, N. Y., which has taken an exclusive license.

While this bolt is new to the trade, it has really been in existence for about 3 years and was first shown on a car at the 1913 Madison Square Garden show. It is intended for a spring shackle bolt but can be used in principle in other mechanisms requiring a continuous feed of fluid oil for internal lubrication.

Felt Wick for Oiling

The lubricating features consist of a main reservoir with a felt wick that is positively attached to a threaded cap plug and one or more feed or filter wicks. The reservoir felt when in position in the hollow shackle bolt is under a slight amount of compression, forcing all the surfaces of the felt against the interior of the bolt. The feed and filter wicks rest against the main reservoir wick and carry the oil to the bearing by capillary attraction. The reservoir wick fits tightly into the hollow bolt and thus forms an efficient oil pump when filling the reservoir. The cap plug forms a handle for operating the wick which can be pulled back in the same way as a plunger.

Operation of the Bolt

In operating the bolt the reservoir plug is removed and the oil put in with an oil gun or squirt can. The wick is then inserted and worked back and forth like a pump plunger and enough pressure can be generated to force the oil through the cross wicks which can be seen in the illustration and out through the ends of the spring bearings. The wick in this manner becomes saturated with oil and when the wick plug is screwed in place against the bolt head the reservoir wick is put under compression and automatic lubrication starts and continues until the main wick is exhausted.

The manufacturers state that about 1200 of this type of bolt were fitted to a series of heavy cars weighing 5100 lb. empty, in 1913. After running from 28,000 to 52,000 miles thirty of these bolts were removed and the wear from them was found to be 0.009 in. as a maximum and 0.002 as a minimum. Sample bolts have already been placed in 1917 cars.

Concealing the Spare Tire

EXPERIENCED motorists who have plenty of mechanical knowledge but no active engineering work to their credit, are constantly expressing surprise that no means has yet been discovered for inclosing the spare tire and rim or spare wheel except on runabout designs with rear decks. They point out that the usual spare tire mounting is a disfigurement to the fine body lines now the rule, and they say they cannot see the difficulty in providing a compartment somewhere at the back of the body, where the spare could be stowed.

Probably nearly every designer has had a good long look at the problem and been unable to discover a way out, but it may be doubted if the matter has ever been studied as carefully as it might have been. To look at a few dimensions, the average back seat cushion is well over 40 in. wide, and few tires exceed an actual 36 in. diameter. The rounded back is coming into favor; in fact, there will be some cars at the 1917 shows with rear ends to the bodies almost hemispherical. Studying these new styles there seems no obvious answer to the question "Why is the spare tire never inclosed?"

Dixie Flyer Battery Mounting Sole Change

Current Source Removed from Motor Vibration — Line Comprises Five-Passenger Touring and Four-Passenger Roadster with Lycoming Engined Chassis

VERY little change has been made in the four-cylinder 1917 Dixie Flyer cars which are now going through production. All the alterations are only detail refinements, with the exception of battery location. In the 1916 chassis the battery occupied the conventional location under the floorboards close to the motor supporting arm. For 1917 it is placed on the left side of the main frame well forward. The reason for this change is that considerable disadvantage was found resulting from the vibration of the engine, and the heat. In the present position the battery is free from heat and vibration and is now so arranged that raising the hood exposes every connection to the eye and allows of considerably shorter lead wires to the starting motor.

Lycoming Power Plant

The power plant consists of a Lycoming engine. This has not been changed and is a four-cylinder 3¼ by 5, L-head design with an S. A. E. rating of 16.9 and, according to the manufacturers, develops 29 hp. at 1900 r.p.m. The cylinders are cast in a block and are of gray iron with the water inlet at the bottom of the casting on the opposite side from the valves. A feature of the motor block is the reinforcement of the attaching flanges where it is bolted to the crankcase, giving maximum rigidity with a minimum of vibration. The head is cast separately allowing space for large valves and also permitting of machining of the cylinders and giving access to the cylinders and valves. The head is also reinforced with ribs preventing warping during machining and permitting a perfect joint between the head and cylinders. Tightness is secured by a copper-asbestos gasket.

The pistons are close-grained iron centered from the inside to secure even thickness of wall. Three piston rings are used, these being eccentric and ground on three sides. The piston pin is hollow of case-hardened steel with a scleroscope test for hardness. The pin is held tight in the piston with the upper end of the connecting-rod forming the bearing through a bronze bushing.

Drop-forged I-beam connecting-rods of 40 carbon steel are used with split type lower ends having a diameter of 1¾ in. and a length of 2⅝ in. on the bearing. The cap is retained by two nickel-steel bolts.

A drop forging is also used for the crankshaft. It is 40-50 carbon steel supported on two bearings. The front is 1¾ in. diameter by 3¼ in. long and the rear 1¾ in. diameter by 3 15/16 long. The flywheel is bolted to a flange on the rear end of the crankshaft, this flange being forged integral and the whole assembly placed in running balance. The bearings are split die cast white metal, adjustable by removing brass shims.

Carbon Steel Camshaft

Low carbon steel is used for the camshaft which is 1 in. in diameter and supported on three bearings. Dimensions of these from front to rear are 1¼ in. diameter by 2 15/16 in. length, 1 55/64 by ⅝ in. and 1 in. by 2 9/16 diameter and length respectively. Scleroscope tests for hardness are used on the cams and each is tested on a special jig for eccentricity.

Helical timing gears are employed to drive the camshaft and other auxiliaries. The camshaft gear is of cast-iron meshing with the steel crankshaft gear. The gears are marked for mesh so that after taking down the engine, retiming is simple. The remainder of the valve action is through flat head pushrods also case-hardened and the valves themselves have gray iron heads fused on steel stems. They are 1⅜ in. in diameter and located on the right side of the engine, so that the steering column does not interfere with valve adjustments.

Lubrication is worked out along the lines of the conventional combination pressure and splash system. The oil is contained in the bottom half of the crankcase which has a capacity of 5 qt. A plunger pump circulates the oil, this being driven by an eccentric on a camshaft. The oil is carried to leads which supply the crankshaft and also the troughs beneath each connecting-rod throw. There is an oil scoop on the bottom of each of the rods, which, due to the design of the oil pan, dips an equal depth regardless of grade and road conditions.

Cooling is by a thermo-syphon system which has several distinctive features. It will be noted from the illustrations that the radiator is on the frame instead of between the frame members, thus placing the lowest level of the cooling water in the radiator above the cylinder jackets, allowing circulation to commence as soon as the engine is started. The inlet and outlet pipes are both extra large, with the radiator being connected to the engine by 2¼ in. hose. Additional efficiency in cooling is secured by having each cylinder barrel independent from its neighbor, thus permitting the free circulation of water all around and between the cylinder walls. Extra large waterways are also provided around the valves.

Stewart Vacuum Feed

The gasoline system comprises a cylindrical gasoline tank, hung at the rear of the chassis, a Stewart vacuum feed and a Carter carbureter, with special adjustment on the instrument board. There is an arrangement for holding a reserve of 1 to 3 gal. in the supply tank and for automatically notifying the driver when the reserve is reached. A 2-in. section of the gas supply pipe works perpendicularly through a specially packed sleeve in the connection at the top of the tank. A stop is provided on the lower section of the pipe inside the tank to limit its travel upward. When the supply pipe is drawn up to the top the vacuum feed draws gas from a point 2 in. above the bottom of the tank. Should the car at some out-of-the-way place run out of fuel, it is only necessary to push down the feed pipe to secure additional feed.

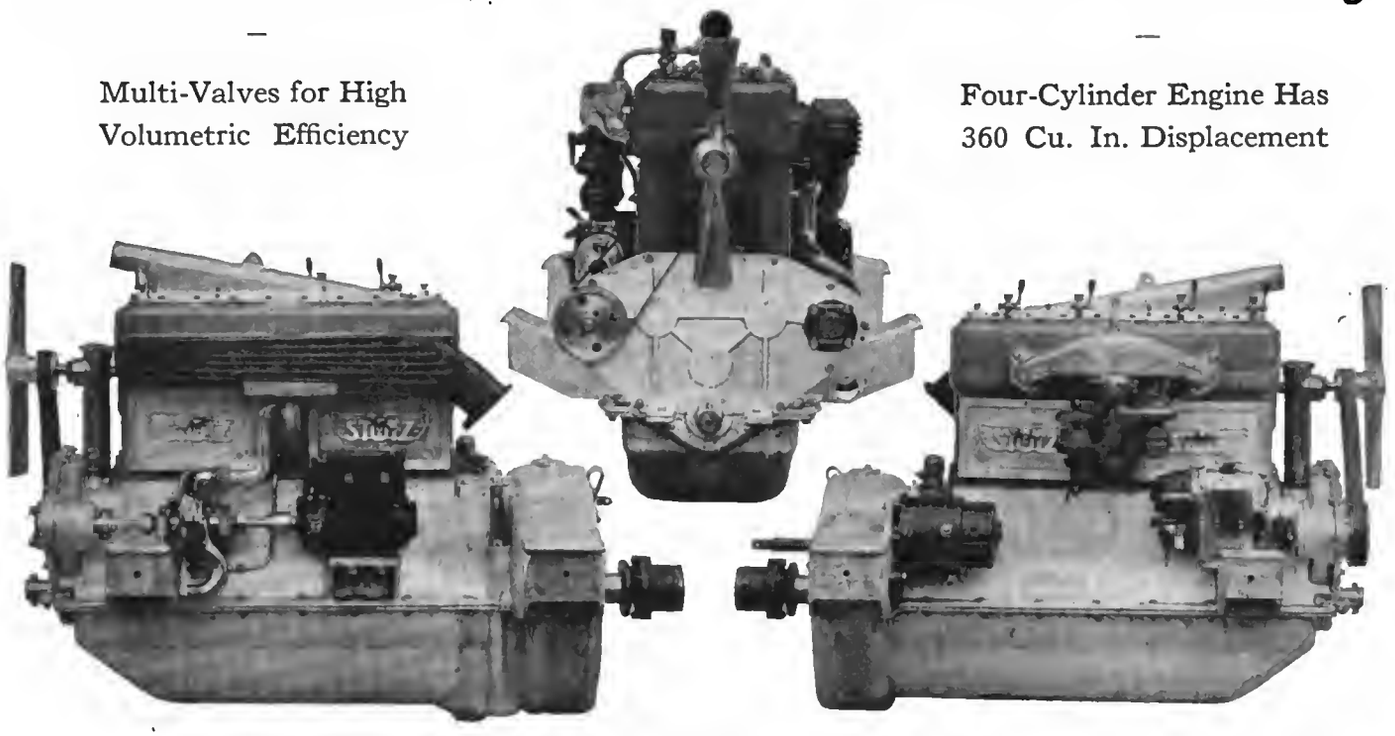
The clutch is a cone of pressed steel with leather facing and with six compensating spring plungers under the leather to secure easy engagement. A straight line drive is secured by underslinging the rear springs and inclining the motor in the chassis, so that when the car is underloaded the drive does not deviate greatly from the straight line. From the clutch the drive is taken through a Grant-Lees standard gearbox with a semi-steel case having a strength of 28,000 lb. per sq. in. tensile. The main shaft has four splines and is of 90,000 lb. steel with a 75 to 80 scleroscope test. It is carried

(*Concluded on page* 363)

Sixteen-Valve Stutz Roadster Ready

Multi-Valves for High Volumetric Efficiency

Four-Cylinder Engine Has 360 Cu. In. Displacement



FOR some time it has been predicted that the tendency observed in racing toward multi-valve cylinders would find its reflection in vehicles intended for ordinary use. The Stutz company bears out this prediction in announcing a sixteen-valve four-cylinder motor placed in a roadster intended for high speed work.

High volumetric efficiency is naturally the object in the greater number of valves per cylinder and the gain is not noticeable except when the ratio of piston speed to displacement becomes such as to require exceptionally high gas speeds. Therefore, in order for an engine of this type to be of use to the average individual who does not expect to travel over the highways at 90 m.p.h., we would expect a powerplant with large cylinders. This is the case in this new Stutz job which has a displacement of 360.8 cu. in. with its bore of 4⅝ and stroke of 6. This gives a formula rating of 30.63 hp. based on the 1000 ft. per minute piston speed. As the engine is intended for high speed work this rating is exceeded to a very large extent. The cylinders are cast in a single block which is a departure from usual Stutz practice. In spite of the compactness of the casting extra large water spaces surround each cylinder and the exhaust ports are all separated, having eight separate entrances into the manifold.

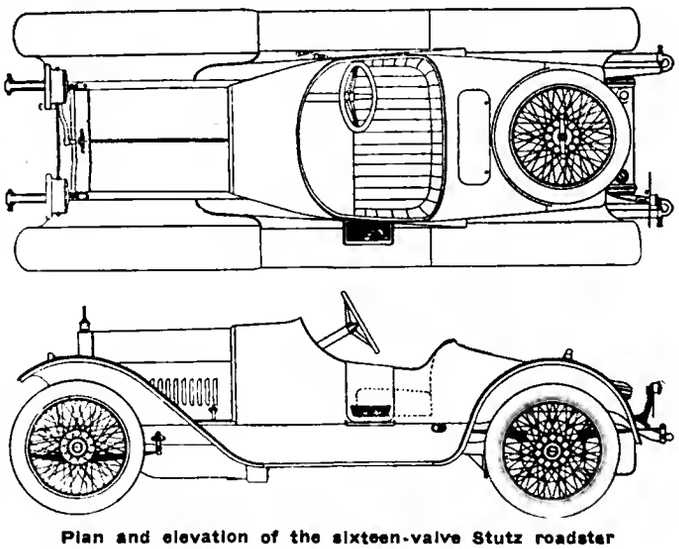
Aluminum alloy is used for the crankcase and this casting is arranged so that the front leg incorporates the breather. This feature has been so arranged to prevent the accumulation of oil vapor over the exterior of the engine, thereby cutting down the collection of dust. The bolts holding the main bearings in place are through bolts with a collar countersunk into the crankcase. They also hold the cylinders in place.

Nickel steel is used for the crankshaft which is supported on three extra long main bearings. In mounting these, the bearing seats as well as the bearings themselves are carefully scraped in so that a solid backing is given the shaft supports. The valves are all operated by roller lifts from the camshaft.

Lubrication is by pressure feed through a hollow crankshaft. Oil is pumped from the reservoir in the crankcase through a main duct cast integral with the crankcase to independent ducts leading to each crankshaft bearing. The stream of oil then passes through the hollow shaft to the lower rod bearings which are fed by a constant flow. The pistons are lubricated from the main and rod bearings, the oil filler is incorporated with the fan bracket and a gage is provided on the side of the crankcase showing the amount of oil in the reservoir.

The fan is a two-blade aeroplane type of an aluminum alloy mounted on an annular ball bearing with an eccentric bearing for adjusting the tension of the fan belt. The intake manifold which is water jacketed is so designed that the carbureter is very close to the cylinder ports and very accessible. Hot air is taken directly from the exhaust manifold by a hot air tube extending between the middle two cylinders.

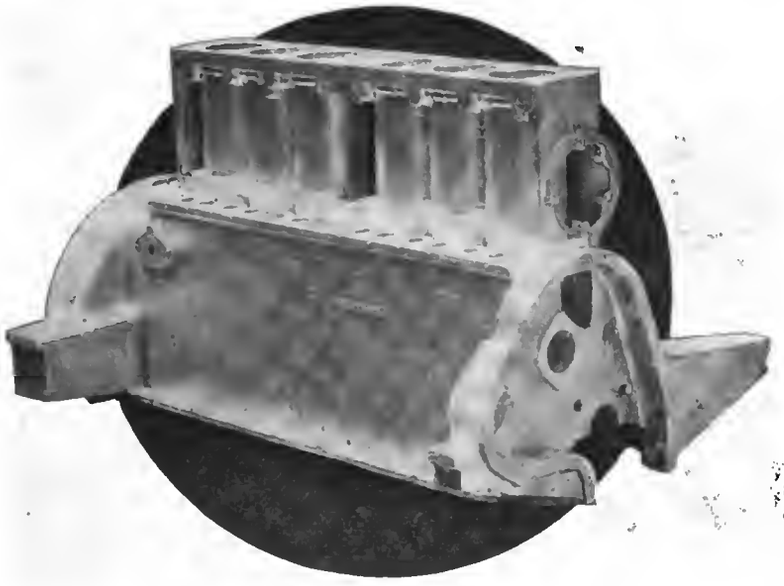
This engine has been in a car for some time and driven several thousand miles. The particular car in which it was installed for trial was a four-passenger job which the makers state has been driven up to 75 m.p.h. fully equipped with the top and windshield up and carrying four passengers. On the same adjustment good fuel economy was secured.



Plan and elevation of the sixteen-valve Stutz roadster

Aluminum Block Engine in New Premier

Two Body Models for the Present — Cutler-Hammer Electric Gearshift Standard



The Premier aluminum engine block

WHEN the Premier Motor Corp. announced this spring that the product of its new factory would be a six-cylinder car with an aluminum engine and magnetic gearshift considerable interest was felt throughout the trade. Now that the full description of the car is available it is seen that the general layout is in every way as modern as the early announcements showed to be the case in these particular details. The new Premier is an entirely separate organization from the old Premier, with a new engineering, production and sales staff and a new factory with new machinery.

A glance at the exterior will show this to be an entirely new car and while unlike anything now on the market it is in many respects a composite of the low-resistance lines of the up-to-date car. From the V-radiator to the rounded stern the entire body gives a suggestion of small resistance and yet roominess. The latter quality is secured to a large extent by the fact that the underhood space that is generally lost to the fan has been utilized for the engine by placing the fan well up in the V-shaped radiator, thus securing so much more room for driver and passengers.

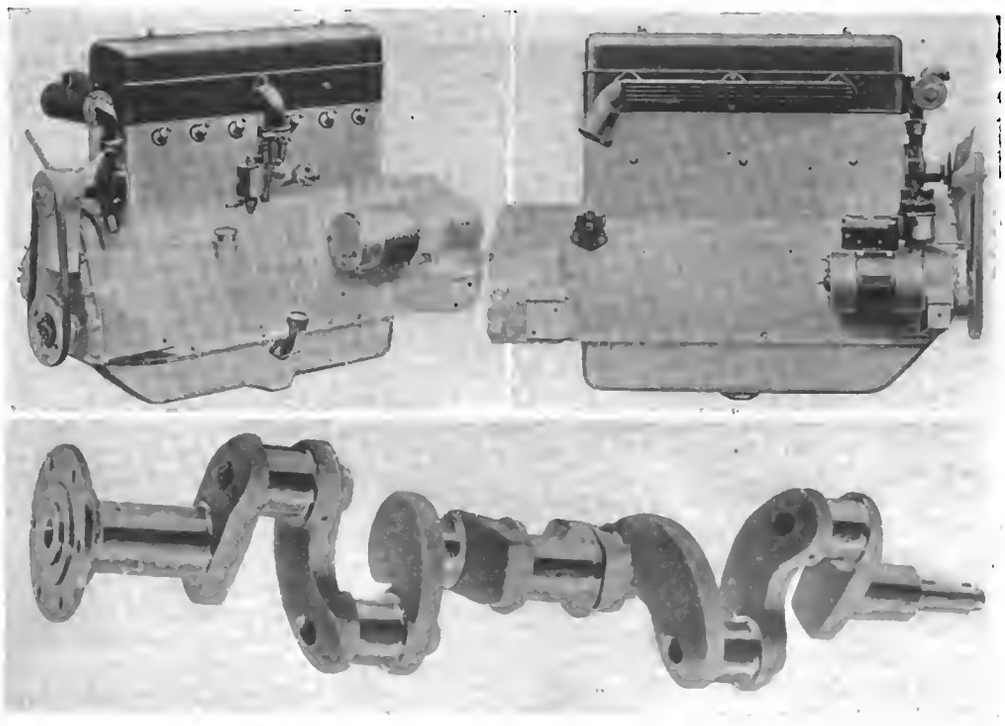
According to present plans between 500 and 1000 of the new cars will be produced during the latter part of this fall. The factory is ample for 20,000 per year production, having an area of 327,000 sq. ft. of floorspace, a complete overhead conveyor system and a plant which is noticeable for its lighting. The buildings and grounds, which cover an area of 40 acres, are in every way suited for the installation of chain or other modern production systems.

Two Bodies at Present

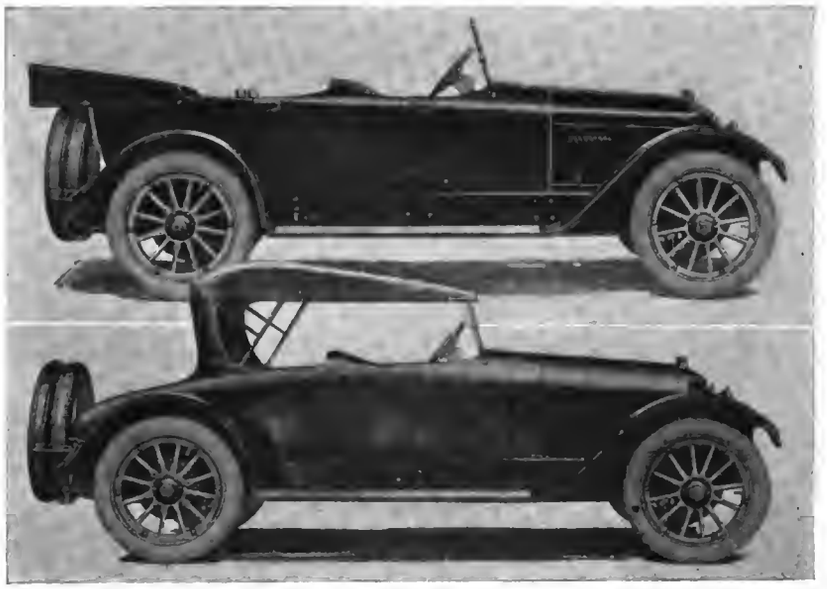
For the present, the line will comprise a seven-passenger touring and a four-passenger roadster selling for $1,685. The principal specifications include the 3⅜ by 5½-in. aluminum motor, single plate clutch, three-speed gearbox, Timken floating axle and a wheelbase of 125 in. with 35 by 4½ tires.

Although incorporating an aluminum block the engine follows standard practice to the extent of being made up in a unit power plant including clutch and gearbox. The power plant is hung at four points, giving a rigid connection to the frame. The six-cylinder aluminum block incorporates the crankcase as a unit. The cylinder head is removable and is of cast iron. With this arrangement valves can be ground and carbon removed directly by simply removing the holding-down studs. The overhead valves are covered by pressed steel cases fitting over the tops of the cylinders. The cylinders are lined with cast iron sleeves which are pressed in the aluminum casting while the aluminum is in an expanded condition due to exposure to super-heated steam. Since the aluminum expands more rapidly than the cast iron the sleeves are held tightly in place on the shrinkage of the cylinder block. When the cast iron sleeve is worn it can be removed by heating the aluminum in the same manner and driving out the sleeve.

Lynite pistons are employed having three rings above the wristpin. The length of the piston is 5⅛ in. which is sufficient to hold to a minimum any tendency toward slap. In the skirt below the piston pin there are two rows of oil holes



Two sides of the Premier aluminum engine with cast iron head and pressed steel valve cover and the counterbalanced curved cheek crankshaft



Illustrating the Premier projectile type touring and four-passenger roadster bodies, which now comprise the line

which will prevent flooding of the combustion chamber. Standard practice is followed in regard to the connection of the piston to the connecting-rod. The pin bearing is ⅞ in. in diameter and has a length of 1 5/16 in. The rod is an I-beam 11 in. long drop-forged from carbon steel. The bearing at the lower end of the rod is 2¼ in. diameter by 1¾ in. in length. The crankshaft is 2¼ in. at the main bearings and is a drop forging from 0.40 carbon steel. The curved-cheek shaft is carried on three main bearings and is counterbalanced on the Wyman & Gordon system. The dimensions of the main bearing are from front to rear 2 3/16 by 3, 2¼ by 2⅞ and 2 5/16 by 3⅝ in.

Fabroil in Timing Gears

Helical gears are used for the camshaft which is carried in the crankcase. The material of the timing gearset is Fabroil, which is the compressed cotton manufactured under General Electric patents. The generator drive is taken off the camshaft which is carried upon three bearings bushed with bronze in the front and die cast in the center and rear. The diameter of the shaft is 1¼ in. It carries the cams integral and these are so shaped as to give the valves a lift of 7/16 in. The diameter of the valve is 1½ in. in the clear, with spring pressures of 40-60 lb. The actual lift of the cam is only 7/32 in. but this is multiplied by 2 in the rocker to give the 7/16 total.

Adjusting the Valves

In making adjustments on the valves there is a nut on the top of the lifter rod. With valves of this size and the overhead arrangement it is expected that the peak of the power curve will be well toward 2800 r.p.m. although no horsepower curves have as yet been submitted. In fact, the engineering department has made a point of good torque at low motor speeds rather than a showy horsepower curve which to the actual owner means little and does not indicate performance at practical speeds.

Combined Pressure and Splash

Lubrication is by a combined pressure and splash system. The oil is forced to the main and connecting-rod bearings and splashed to all the other bearing surfaces. The reservoir is in the lower half of the crankcase and from here the lubricant is taken by a gear pump driven by spiral gears off the camshaft. The pressure is regulated by a by-pass to the timing gears and owing to the fact that the crank cheeks are curved in carrying out the balancing system, oil pipes are placed across the curvature in the cheeks. The spray off the connecting-rod bearings gives all the oil that is considered necessary. The oil capacity of the crankcase is about 8 qt.

A feature of the oiling system which is somewhat different and is the idea of Earl Gunn, who is chief engineer, is in the knurling of the piston skirt. Diagonal lines about 1/32 in. apart are carried across the piston skirt. The lines run at about right angles to each other and provide space for a small amount of oil to work its way along the surface of the piston. It also gives room for the metal on the raised portion to spread out should there be any tendency to stick in case the oil level becomes low. While maintaining the oil film this groove forms an oil trap which tends to make each unit of oil do its work before it is again allowed to drain back to the crankcase. The oil filler and oil level gages are on the left side of the engine while the oil pressure is registered on the dash.

In working out the cooling system the water pump is mounted on the front of the cylinder block, the impeller shaft for the pump and the fan shaft being common and driven by a V-belt off the crankshaft. The reduction between crankshaft and the impeller-fan pulley is 1 to 1½. Another feature of the cooling system which is of interest is the use of a thermostat for maintaining the correct water temperature. With this system the water does not flow from the cylinder jackets until the temperature in these jackets becomes high enough for efficient combustion. The thermostat then permits the circulation. In the meantime the pump simply circulates the water through the radiator. This unit is a honeycomb with a capacity of about 6 gal. including the volume occupied by the waterjackets. The by-pass for the thermostat is located over the water pump at the high water level. There is an opening on the camshaft side of the waterjacket casting which considerably simplifies the foundry work on this casting. Over this opening a cover is bolted on, inclosing the push rods. The fan is really the only exposed moving part. This is a four-bladed aluminum casting 14 in. in diameter and the belt which drives it is mounted in front of the fan in order to take up as little underhood room as possible and to secure full benefit of the V radiator.

Two-Unit Electric System

Electrically, the Premier car is Delco equipped, as this takes care of starting, lighting and ignition. It is a two-unit system in which the generator carries the ignition coil and distributer. This unit is driven from the timing gears while the cranking motor engages through a Bendix gear to the teeth on the flywheel. The battery is 100 amp.-hr. Willard mounted between the engine and frame under the hood, an accessible position, and yet the battery is out of sight. The spark plugs are set into the side of the bolck casting at an angle.

On the rear of the crankshaft there is a flange to which is bolted the 15-in. 60-lb. flywheel. This incorporates the Borg & Beck single-plate clutch. The teeth are cut directly on the wheel and give a ratio of 120 to 13 to the starting pinion.

Gearshifting is accomplished by the use of the Cutler-Hammer magnetic shifter and is now in its improved form. Basically, however, the principle is the same as has been described several times, with the power supplied through solenoid coils operating the selector and shifting units. In installing the shifting arrangement care has been taken in the clutch move-

ment to allow the driver to declutch the engine without shifting gears, the shift being made only on a full depression of the pedal. Aluminum is used for the gearset housing with a sheet steel coverplate.

An S. A. E. bell housing is used but on account of the arrangement of the Bendix gear the holes are differently spaced than the S. A. E. specifications. All through the car, however, S. A. E. standards have been used as closely as possible, especially as regards material.

Frame Is Strong

There are two universals on the propeller shaft and the rear axle is a Timken spiral bevel unit with a ratio of 4 5/11 to 1. This is the standard floating unit. The frame construction is extraordinarily sturdy, having a channel section 8 in. deep with a 2¼ in. flange of ⅛-in. stock. The flange, of course, tapers in different parts of the chassis. The channel section is so arranged that the web forms the splash apron and the stay bolts for the hangers pass directly through the flanges. The springs are semi-elliptic, 58 in. long and 3¼ in. wide. They are a product of the Perfection Spring Co. and take the drive as well as the torque. The steering gear incorporates a worm and full wheel.

Suspended from the rear of the frame is a 24-gal. gasoline tank fitted with a long gooseneck filler opening making filling possible from the side of the curb without using a funnel or clashing with the spare tires. The tank is also so hung that the frame protects it from rear collision. From the tank the fuel is carried to the carbureter by a Stewart vacuum system.

Premier designers have been particularly fortunate in securing a very pleasing combination of body lines. From the radiator, which is a very decided V, the impression is one of a smooth, round, slightly tapered cylinder. The top of the hood is a straight line from radiator to windshield and the sides have the incurve at the top which merges into a cowl behind the front seats. The Premier people call it a projectile type of body and the name seems a particular happy one as applied to the four-passenger roadster. A tilted windshield adds to the effect.

Body room, particularly in the seven-passenger car, is unexpectedly great. An additional 6 in. is obtained so that there is more passenger capacity than ordinarily would be regarded as possible on a wheelbase of 125 in. One feature which will be appreciated by tonneau passengers is the fact that those in spare seats have as much room as those in the tonneau seat proper. This is obtained by cutting deeply into the back of the front seats foot and leg space which is covered up when the spare seats fold in. Front seat passengers are equally well cared for and exit and entrance from the driver's side is made easy by a tilting steering wheel and the abolition of the gearshift lever. The tonneau seats measure 44 in. from upholstering to upholstering. The latter is of the straight, vertical pleat pattern.

Wide doors and comfortable auxiliary seats in seven-passenger touring

The dash instruments are easily seen—note position of electric gearshift control on steering column

The four-passenger roadster is supplied with doors both front and rear and is not so close coupled.

—

Dixie Flyer Battery Mounting Changed

(*Continued from page* 359)

on a double row of S. K. F. self-aligning ball bearings. Between the stem gear and the main spline shaft a roller bearing is used. The material in all gears is 3 per cent nickel steel testing up to 120,000 lb. sq. in. and allowing of quite narrow gears and a short case.

The rear axle is floating with chrome nickel-steel shafts and gears. The final drive is spiral bevel mounted on high duty roller bearings with end thrust bearings on either side. A feature of the rear axle is that all gears and bearings are adjustable, thus permitting a continuity of good mesh and a reduction of noise due to wear.

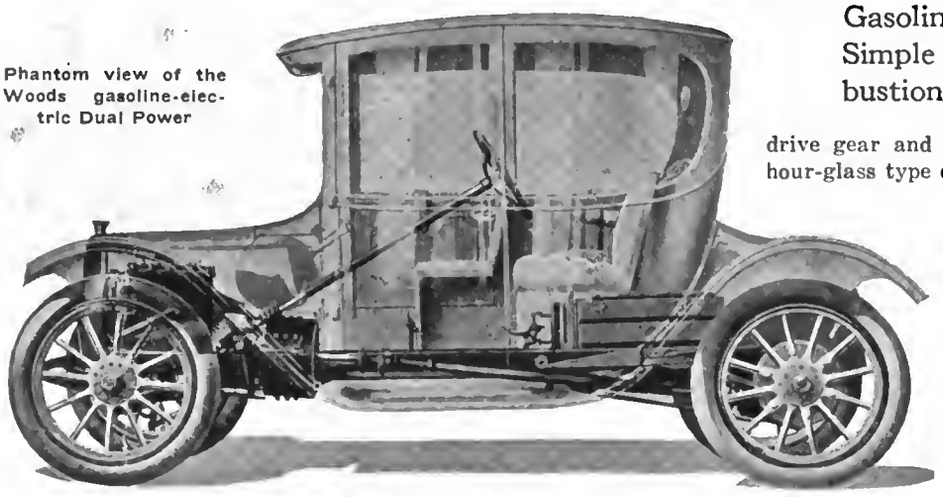
Electrically, the Dyneto two-unit system is used for starting and lighting and the Connecticut system for ignition. The battery is a Willard. Bendix drive connects the starting motor with the engine through the flywheel ring gear. A wiring diagram is placed on the dash of each car and the individual circuits are marked in different colors so that non-technical owners may have a clear picture of the electrical connections. Each individual circuit such as headlights, tail and cowl lights, ignition and horn is equipped with a separate fuse and the block carrying the fuses is on the dash beneath the hood. The generator cuts in at 10 m.p.h.

Structurally, the frame is a straight pressed steel channel with four cross members and a noticeable absence of castings. Where these are used they are of steel in place of the malleable metal. Drop forgings are used wherever possible to secure strength with minimum weight. The wheelbase is 112 in. Steering is irreversible and the wheels are artillery, using 32 by 3½ tires on demountable rims.

The line comprises two separate bodies. There is a five-passenger touring and a four-passenger roadster, the latter having the cloverleaf seating arrangement. The touring car is a straight line design from the radiator to the cowl with a slight curve in the side rail line. Standard finish is Brewster green with highly crowned fenders in black enamel. The roadster follows about the same lines as the touring car and has a sloping windshield. Individual seats are used in the forward compartment with the rear seat wide enough to accommodate two persons. The top is a one-person design with quick-detachable side curtains and the price of $795 includes complete equipment.

Simple Control in Woods Dual Power

Gasoline Electric Incorporates Simple Linkage of Internal Combustion and Electrical Units



Phantom view of the Woods gasoline-electric Dual Power

AN electric car, a gasoline car or a vehicle in which both powers may be utilized at once, with the elimination of the greatest inconvenience in electric cars, namely dependence on charging stations, is the Woods Dual Power car.

In the mechanism of the car there are really but three units, irrespective of the driveshaft and rear axle. The gasoline engine is under the hood and directly behind it is the electric motor, a unit is the same drive line. Located under the front seat is the storage battery set. The connecting unit between the gasoline and electric motors is in the form of a magnetic clutch which is simplicity itself. When the gasoline control lever is raised about an inch from full retard the flywheel of the gasoline motor becomes magnetized. The magnetic force pulls a copper disk against the face of the flywheel and the electric motor and the gasoline engine are connected.

Four-Cylinder Block Engine

The gasoline engine is a block cast four-cylinder, with 2½-in. bore and 3½-in. stroke. Because of its small cylinder sizes and its high speed operation the engine is very smooth running, being nearly as quiet as the electric motor. Lubrication is effected by a gear pump which lifts the oil from a lower chamber to a compartment around the valve tappets, whence it flows by gravity to the various bearings. Ignition is Atwater Kent, with automatic spark advance. Cooling is thermo-syphon through a honeycomb radiator.

A one-piece gasoline tank with a capacity of 9 gal. is under the cowl. The Exide battery is specially constructed for this car and has twenty-four cells with eleven plates each, considerably smaller than the batteries required for driving all-electric cars.

Much of the smooth riding qualities of electrics has been attributed to the heavy batteries suspended low in the rear or center-rear of the car. With a much lighter battery the Woods car is equally as easy riding as the former all-electrics produced by this same company. This, the makers say, is due to the use of liberal-sized cantilevers on the rear. The front is half-elliptic suspended.

The rear axle is semi-floating with the wheels mounted on driving shafts which ride on Bock roller bearings. The axle tubes are of steel tubing, swaged to shape and bolted through the flange to the axle housing which surrounds the drive gear and differential unit containing the Baush hour-glass type of worm gear.

The body is an attractive combination of characteristic gasoline and electric car types. It is aluminum-panel construction and the coupé is the only model offered. The doors are wide and contain windows which may be lowered. The front and rear windows may also be opened. The car will comfortably seat four passengers, the driver's seat being staggered ahead of a spacious seat which will take care of two and in front of which is an auxiliary seat which folds out of the way against the dash.

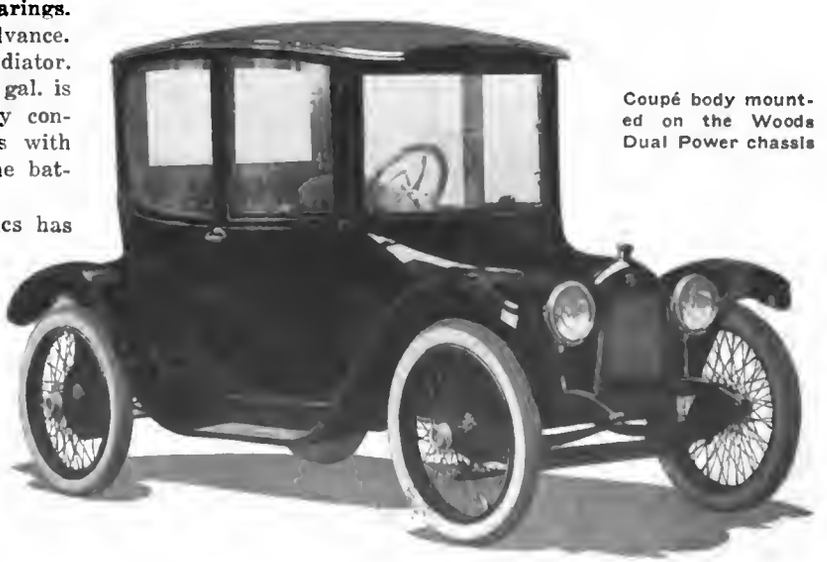
On the instrument board is an ampere-hour meter and ammeter combined and a Stewart-Warner speedometer. There is a three-gang switch for lighting.

The oscillating movement of the pedal is for the purpose of opening and closing the switch of the electric motor. Of course this same operation can be performed with the hand control lever. With the hand lever set at an operating position and the pedal pad oscillated forward there is no current passing to the motor. A movement of the foot and the switch engages and the car starts.

Reverse by Electric Motor

The gasoline engine drives one way only, there being no gearset, and so the electric motor must be called on to run the car backwards. Oscillate the pedal pad forward, place your heel on the small lever against the heel board under the driver's seat, oscillate the pedal backward, the action of the electric motor is reversed, and the car starts backward.

The price of $2,650 includes a power-air pump, mounted on the right side of the gasoline motor; and a motor-driven warning signal. Wire wheels are listed at $25 additional and the same figure will equip the car with slip covers. Cars in special color effects to suit the individual tastes of owners



Coupé body mounted on the Woods Dual Power chassis

will be produced for $100 additional. Deliveries of the new car are already under way.

The controls are simply arranged so that none of the easiness of drive that makes the electric car so popular with women drivers is lost. The absence of complication is marked and a large part of the actual mechanical control is automatic. As in gasoline cars, practically all the driving is done through pedals with very little manipulation to cut into the effectiveness of the hands in steering. There are no gears to shift and all the hill work is simplified by the action of the electric units which take up the work where the gasoline leaves off.

Three-quarter rear view, showing neat lines of the Woods Dual Power

Tourabout Body on Empire Six Chassis

THE latest of the four-passenger body designs is the new Empire tourabout which is fitted on the six-cylinder chassis. The new body was designed to provide a snappy type of vehicle of larger seating capacity than the roadster. In exterior line the body carries out very well the suggestion of a speedy yet roomy vehicle. From the high roll cowl there is a gradual downward taper to the rear deck to curved sides without a break or corner at any point.

It is really a four-passenger car in that there is an abundance of room for four persons to be seated in comfort. The front seats are individual with a wide aisleway which gives easy access to the rear seats.

A roomy rear back department is supplied for luggage and access to it may be had by dropping down the back of the rear seat which forms the door to the compartment. It is large enough to accommodate two suit cases and other touring accessories.

Even with the ample room between front and rear seats, the close coupled advantage of all passengers riding between the axles produces easy riding. The color scheme consists of green for the body proper with black hood, fenders and running gear.

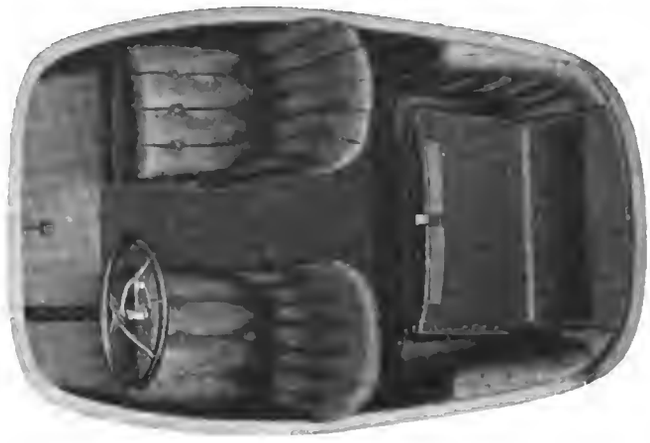
The Empire six chassis has been described before, so it will be enough to say that it comprises a six-cylinder engine 3¼ by 4½ in., 120-in. wheelbase and 34 by 4 tires.

—

Benzol and Alcohol as Fuel

For several years the Paris General Omnibus Co. ran all its De Dion Bouton and Schneider buses on alcohol carbureted with 50 per cent benzol. Later, and until immediately before the war it used benzol only. The disadvantages of the mixture were difficulty in starting and the necessity of cleaning out the combustion chamber more often than with the use of gasoline. The bus company found that their fuel consumption was at the rate of 0.176 gal. per mile with benzol only; 0.180 gal. with gasoline, and 0.2 gal. for alcohol and benzol. In all the annual French army truck trials held prior to the war, one-third of the total distance had to be accomplished on an alcohol-benzol mixture, one-third on benzol, and one-third on gasoline. Except for the difficulty in starting from cold the alcohol-benzol mixture was as satisfactory as the other two fuels.

Since the outbreak of the war there has been no use of benzol and alcohol in the motor services of the Allied armies, these two fuels being monopolized for the making of explosives.



Above—Seating arrangement of the Empire four-passenger roadster, showing passage between front seats and relative capacity of rear seat. Note fold-down back on rear seat and also amount of leg space in rear

Left—The new Empire four-passenger roadster, showing the low lines which maintain the roadster form and yet give the car the capacity of a small touring body. Note torpedo stern and manner in which top covers rear seat

Ammeter Not Advisable on Cole 4-40

EDITOR THE AUTOMOBILE:—I have a 1913 model Cole 4-40 touring car that is equipped with a Delco lighting and starting and ignition system and desire to install an ammeter on same. Please give instructions in installing it and what should be the graduations of the ammeter.

I use a 12-cell type SD-3 Exide battery and desire to charge the batteries without taking them off the car. Using a 6-volt direct-current circuit, could I not disconnect the wires from the generator and connect source to them and charge them that way?

Which are the generator terminals and at what amperage should the battery be charged? Please give diagrams of the above.

Senath, Mo. L. A. C.

—It is not recommended that such an installation be made on this particular system because of the fact that on the 6-24 volt system the meter would have to register the cranking current as well as the charge and discharge rates when connected to show the net charging current. The installation would, therefore, fall for an ammeter having about 50 amp. as a maximum on each side, and in view of this fact, it is not believed that the meter would do any good, particularly as the ampere ammeter on this system enables one to get a fair idea of whether or not the battery is being properly charged.

In regard to the charging of the batteries, this is a perfectly feasible thing to do from a 6-volt source by connecting the positive terminal and negative terminals in parallel and then connecting the 6-volt source as shown in Fig. 1.

All terminals of the generator are used when the machine is generating current. Referring again to the diagram, these terminals are numbered 1, 2, 3 and 4. The No. 3 terminal is the negative one which is connected to the negative terminal at the battery through the wire and connections in the controller switch and the No. 4 terminal is also connected through the wiring and connections to the positive terminal of the battery. The No. 4 terminal, however, is one end of the reverse series winding. The 1 and 2 terminals are the positive shunt field terminal and the positive brush lead and when connected to the meter contacts permit the generator to charge the battery. If there are no connections between the Nos. 1 and 2 terminals the generator will not charge in the proper direction.

Olds 1907 Loses Power on High

Editor THE AUTOMOBILE:—I have an Oldsmobile model A roadster, No. 61047 which runs all right on reverse, low and intermediate, but when I shift into high the car comes to a bucking stop, and then if shifted into intermediate it will act the same way. Will you kindly explain as to what causes this trouble and, if possible, publish a sketch of both gearbox and differential?

Pittsburgh, Pa. F. J.

—In a similar case to the one you mention, the balking was found to be due to worn out pistons and cylinders; in other words, the engine had no power, and as soon as it was thrown into high speed it stuck. As this car is a 1907 model, it is very probable that after 9 years of service the pistons and cylinders as well as the valve will be in bad shape.

Efficiency of Final Drive

Editor THE AUTOMOBILE:—Which mechanism delivers the most power to the rear wheels of an automobile, viz., chain drive, carried through jackshaft to sprocket and chain to rear wheels, or direct drive from transmission to the bevel gears in rear axle then delivered to wheels through semi or full floating axle?

Seattle, Wash. W. A. W.

—The entire matter of friction loss depends on the amount of bearing surface as well as in the manner of drive. A table giving the transmission efficiency of different types of mechanism has been worked out by Worby Beaumont and is considered quite reliable. This table is as follows:

Source of Loss of Power	Amount of Loss Per Cent	Efficiency Per Cent 100
When driving direct:		
One chain	3.0	....
One and one-half pairs of bearings	7.5	89.5
With epicylic speed gear in operation, add	15.0	74.5
When driving direct:		
One set of gears	5.0	....
Two pairs of bearings	10.0	....
Partially active bearings	3.0	82.0
With change-speed reduction gear in operation, add	12.0	70.0
One set of gears	5.0	....
Three pairs of bearings	15.0	....
Equivalent of two chains	6.0	74.0
Two sets of gears	10.0	....
Four pairs of bearings	20.0	70.0
Two sets of gears	10.0	....
Five pairs of bearings	25.0	....
Equivalent of one chain	3.0	62.0
Equivalent of three sets of gears	15.0	....
Five pairs of bearings	25.0	60.0

Cannot Change Buick 25 Ratio

Editor THE AUTOMOBILE:—I have a 1914 model B-25 Buick touring car which is geared 13½ on low, 6 on second and 4 on high, which is a little too high a gear for this rough country. I wish to change the gear so I will have a 16 to 1 on low, 8 or 8½ on second and about 5 or 5½ on high. What would be necessary to make the desired change and where could the necessary parts be obtained? Also, about what would the total cost be?

Newcastle, Wyo. L. R. K.

—The Buick company cannot supply special gear ratios for these cars, owing to the fact that there is just room in the differential housing to take care of the present ring gear and there would be great difficulty in fastening a smaller pinion to the shaft.

Eight Cylinders Placed in Line

Editor THE AUTOMOBILE:—What would the crankshaft for an ordinary eight-cylinder engine look like in case all the

cylinders were put in line? Is there any angle other than 180 deg. between the different crankpins?

Milwaukee, Wis. W. F. O.

—The simplest way would be to have all the cranks in the same plane just like two four-cylinder crankshafts both together. An arrangement with cranks at 90 deg. would, however, be possible.

The easiest way to explain it is to say that with eight cylinders in line you have the equivalent of two four-cylinder engines coupled and you can regard the first four-cylinder as one engine and the second four as the other or you can regard cylinders 1, 3, 5 and 7 as one four-cylinder engine and 2, 4, 6 and 8 as the other.

Packard Uses Double Distributer

Editor THE AUTOMOBILE:—Does the Packard company use a separate coil and time for each half of its twin six? Kindly explain how same is timed.

2—Who makes the engines used on Paige, Jeffery, Mitchell, Kissel, H-A-L, Studebaker and Reo cars?

3—What ignition is used on the H-A-L twelve?

Mount Hope, N. Y. T. K.

—No. There is a double distributer, however, and the timing is exactly the same as for two independent six-cylinder engines, each half of the distributer taking care of a set of six cylinders.

2—Paige, Rutenber, small six, and Continental, large six; Jeffery, Buda on the six and own on the four; Mitchell, own engine; Kissel, own; Studebaker, own; Reo, own; and H-A-L, Weidely.

3—Remy ignition.

Rebuilding Haynes for High Speed

Editor THE AUTOMOBILE:—Am rebuilding a Haynes model Y for speed. Have cut wheels down to 32 in. and changed ratio to 2½ to 1. Am cutting aluminum pistons with head slightly crowned.

In your opinion would I gain anything by changing timing of valves, and if so what timing would you advise?

Galion, Ohio. R. W.

—Possibly some speed would be gained by pushing the timing of the exhaust valves ahead about one tooth in the camshaft drive. This would probably affect the low speed running but may increase the power of high speed. The inlet valve timing should be changed to open around 10 deg. late and close from 45 deg. to 48 deg. after bottom center. This being a rather old model, built in 1910, the valve sizes are not sufficiently large to make for high speed and there is a possibility that very little, if anything, will be gained.

It must be remembered that between the years of 1910 and the present time engines have undergone a distinct change in design. One of the factors in this is the falling off in the quality of fuel. The engines of that time cannot burn the present grade of low-grade fuel to the same advantage as the engines of to-day which are designed to have the incoming vapor preheated to some extent.

Making a Racer Out of a Ford

Editor THE AUTOMOBILE:—I want to cut a Ford down to racer type. Do not care for speed of more than 50 miles, but as Pittsburgh is very hilly, must have power enough to climb hills on high. I realize by cutting the machine down it will cut the wind resistance and I figure on changing the gear ratio on high to 3 to 1.

Would the regular Ford engine give me power enough to take stiff hills on high with the gear ratio changed to 3 to 1, or would I have to install aluminum pistons to get additional power?

Pittsburgh, Pa. W. J. G.

—No doubt you would get more satisfactory results if you are looking for high speed with lighter pistons. As far as taking hills on high gear is concerned, it is doubtful if the lighter pistons will make any difference, as the effects of light pistons do not come in until the speeds are quite high. With a 3 to 1 gear ratio and a very light chassis, the Ford engine has a great amount of hill-climbing power.

Installing a Battery for Headlights

Editor THE AUTOMOBILE:—I want to make a change on the lighting system of my Ford car. At present I have a Prest-O-Lite, but my lamps are about shaken to pieces and I have a good pair of electric reflectors, a motor-driven signal and batteries are expensive and not very strong either unless I get about six of them. Taking everything into consideration, I think it would be better if I would trade for a storage battery. I can get a 120-amp. battery charged here for $1.25 and would like to know how many hours this capacity battery would burn three lamps, all consuming 6 amp. I have a house-lighting system handy, of 110 volts, alternating current (Keokuk), and I would like to know about what the cost would be to arrange it to charge my battery, also the instruments needed. My ideas are to have a light, one that is dust and mud-proof and handy.

Would it be necessary to install fuses and the method of placing on the lines, etc., for two headlights and tail lamps, also trouble lamp off and on socket to wire direct from battery, so as not to use all lights when using trouble lamps?

Please sketch a diagram of wiring and where to place fuses, if needed. Would it be a safe place to put the fuses behind the foot or heel board next to the gasoline tank and the switch directly in front—that is, on the front side?

Vandalia, Mo. J. R.

—Probably the best way to take care of your lighting and warning signal would be to install the battery as you suggest. A 120-amp. battery would only support three lamps which consume 6 amp. for a period of 6 2/3 hr., but there is no reason why you should use such large lamps as this. A 6-amp. lamp with a Tungstun filament would give about 36 candlelight power lights and you will find that these are ample and besides will only require about 1 amp. each in current. In fact, the tail light can be smaller than this.

It will not be necessary for you to install fuses, but simply to wire the lamps directly to the battery and switch. The same applies to installing the trouble lamp.

To secure an outfit that will enable you to charge your storage battery from 110-volt alternating current system, would be quite an expense, as it would be necessary to get a rectifier and also to fit up a large complicated switchboard. It would be better to get the small lamps and battery and to have the battery charged whenever it is exhausted.

If you are doing a very large amount of night driving you will probably secure greater satisfaction from the gas lamps, but for a small or medium amount of night driving the electric lights will be very convenient.

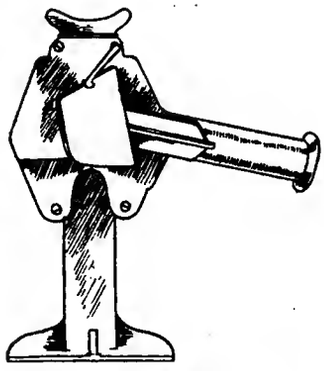
ACCESSORIES

U. S. Jacks

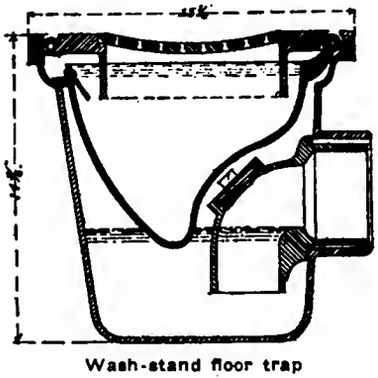
THERE are three styles of U. S. jacks. One is a tire-saver, made in two sizes, the smaller having an adjustment of 11 to 18½ in. for pleasure cars and the larger with an adjustment of 12 to 20 in. for heavy passenger cars or trucks. The lever is so arranged that when the jack is raised it is automatically locked. The unique No. 2 jack is a malleable iron design for heavy passenger cars, and has an adjustment of from 9½ to 17 in. It requires about 30 lb. pressure on the end of the handle to lift a heavy car. No rivets are used in its construction, and screw holes are provided so that it may be mounted on a large block of wood for stability. The unique No. 1 jack is similar in design to the tire-saver, and is recommended for cars weighing up to 2500 lb. It has an adjustment of from 9½ to 17 in.—U. S. Mfg. Co., Mansfield, Ohio.



United States jack

Wash-stand Floor Trap

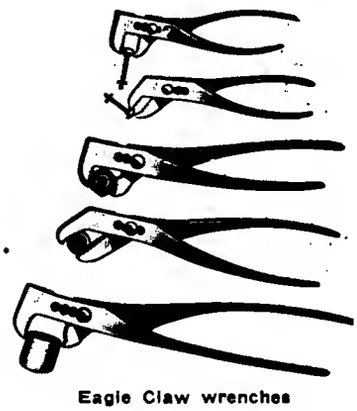
With the ordinary type of trap the sediment washed from the cars is certain to settle in it and gradually fill it up. In the Lynn trap this difficulty is overcome by providng a sediment cup into which the water drains directly from the floor. Most of the dirt remains in this cup and comparatively clean water overflows into the bottom of the trap and thence to the sewer. The cup, like the floor grating above it, is hinged, so that it is but a moment's work to empty the contents of the cup. No. 1 size has 3-in. outlet, No. 2 is similar but with polished brass top grate, No. 3 has twice the capacity of No. 1 and No. 4 is the same as No. 3 but with polished brass top grate and frame. Prices: No. 1, $15; No. 2, $50; No. 3, $30, and No. 4, $70.—Lynn Stall Co., Lynn, Mass.



Wash-stand floor trap

Combination Gasoline Lock

The device is operated from the dash or cowl board and consists of three disks revolving in a chamber and engage with each other in the same manner as the disks of a combination lock. Each disk is pierced by a hole. When the lock is open the holes of all three disks are in alignment and the gasoline flows through unobstructed. The disks are controlled by the numbered dials, but a single turn on the dial throws these holes in the disk out of alignment and positively locks the flow of gasoline. A great variety of numbers may be used, making combinations of either two or three figures, and the owner can set his lock to any desired combination in case of discharging a chauffeur. The combination lock may be opened in the dark by feeling the notches. Inside the device is a strainer and filter cup which prevents dirt from clogging the needle valve seat. The cup also serves in removing water from the gasoline and the impure grease may be periodically removed by unscrewing the cap at the bottom. The price is $3.50 for cars with cowl boards and $3 for straight dashboard equipment.—Turner Brass Works, Sycamore, Ill.



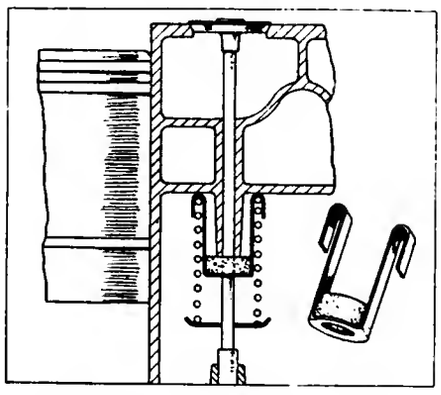
Eagle Claw wrenches

Eagle Claw Wrench

Several styles of Eagle Claw wrenches are made and are designed to handle all sizes and shapes of work. The different sizes are adjustable from zero to 2 in. Prices: 7 in., $7.20 per dozen; up to 13 in., $15 per dozen.—Mechanical Specialties Co., People's Gas Building, Chicago, Ill.

Apco Valve Packing

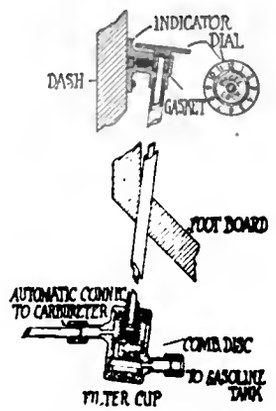
This is a simple device for Fords designed to prevent leakage through worn valve stem guides. It consists of a thick felt washer, which goes around the stem and is pressed closely to the guide by a fitting which is attached to the top of the valve spring. New felt washers should be put in every time the valves are ground. Price, 50 cents; felt washers, 12 cents per dozen.—Auto Parts Co., Providence, R. I.



Apco valve guide packing for Fords

Westinghouse Charging Outfit

This rectifier outfit consists of a transformer-reactance and Cooper-Hewitt rectifier bulb mounted on a cast-iron frame. The transformer is so arranged as to deliver, without the use of extra resistance or reactance coils, the gradually decreasing current best suited for battery charging. Terminals are provided for connecting the alternating-current lines and the battery circuits to the outfit. Fuses for overload protection are placed in both the alternating and direct-current circuits. A simple starting switch, the two link connectors, by means of which transformer connections are changed to suit any particular battery and line voltage within the limits of the outfit, are additional features. This outfit has been designed pri-



Combination gasoline lock

Icy-Hot motor restaurant

marily for the car owner who is not an electrical expert.—Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

Icy-Hot Motor Restaurant

A motor restaurant at a more reasonable price than the wicker baskets used by many owners. The new models, made for parties of four or six, have cases of basswood, a material that shows very little tendency to warp. The box is 12 in. high, 15½ in. wide and 9½ in. deep. The color of the case is black, with a finish like patent leather, and impervious to water. The lining is in Bakst style.

It contains plates, knives, forks, napkins, cups, spoons and jelly jar and a large lunch box. The lower half has three divisions, two for vacuum bottles or jars and the other for fruit, crackers, cake, etc. There is a division above for an Icy-Hot jar or bottle, so that three vacuum containers can be carried. —Icy-Hot Bottle Co., Cincinnati, Ohio.

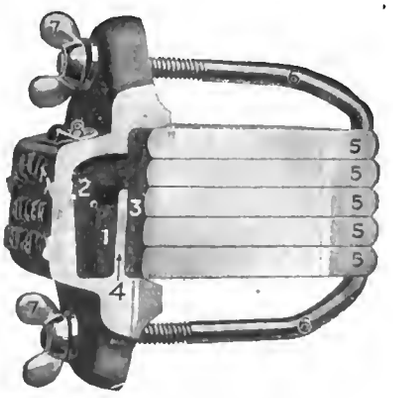
Babbitt Spring Oiler

This is a spring lubricator consisting of a felt whip housed in a metal casing and clamped to the side of the spring. Oil is supplied once a week. Price, $4.50 to $12 per set.—Babbitt Spring Oiler Co., Penn Building, Cleveland, Ohio.

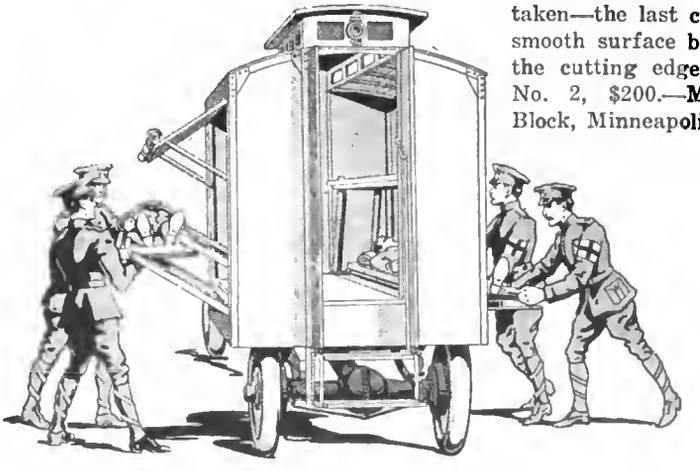
Blackmore Convertible Ambulance

This convertible ambulance body, with side loading feature, is adaptable to any chassis. The sides of the body swing out on pivots and cause trays that are built in combination with the sides to project beyond the body, and upon them stretchers are placed, after which the trays and stretchers are lifted in a horizontal position inside the ambulance. One stretcher may be placed slightly higher than the floor and another above it on the same side, while opposite them another tray may be utilized as a bench or other stretchers may be loaded, as the first two stretchers. These bodies are suitable for military use, hospitals and city police work.—Charles C. Blackmore, Dayton, Ohio.

Westinghouse charging outfit which consists of a transformer-reactance coil and a Cooper-Hewitt rectifier both mounted on a cast iron frame



Babbitt spring oiler



Left—Blackmore convertible ambulance body with side loading feature. It is adaptable to any chassis and is suitable for military, hospital and police work

Instant Back Curtain Light

This accessory consists of a frame designed to fit the back curtains of 70 per cent of all cars. The frame has flexible edges, to which the removable celluloid light is attached by snap fasteners. Price, $2.50. Auto Patent Equipment Co., 216 Post Square, Cincinnati, Ohio.

Universal Night Signal

This night signaling device consists of a blown flesh-colored celluloid hand which fits over a tubular flashlight equipped with a special reflector for the lamp. The Universal signal allows the same well-known method of signaling to be used at night as during the day. The hand may be detached and the flashlight used as a trouble lamp in the garage or on the road. It sells for $2.50. —Yankee Mfg. Co., Milwaukee, Wis.

Steer-Adius for Fords

The Steer-adius is a combination of two devices, one for preventing rattle in the front ball joint and the other for making steering easier. The former is a central radius rod running from ball joint to axle and is adjustable, while the latter consists of two heavy coiled springs fastened to this central rod and with connecting rods running to the tie rod extremities. The device may be attached in a few minutes. It lists at $2.50.—Modern Specialty Co., Racine, Wis.

Perma-Tite Tire Patch

This is a tube and tire patching outfit for all sizes of repairs. The patch is applied cold, a thin coat of the cement being applied and the patch put in place. Permanent vulcanization is said to take place, due to the heat and air pressure of the moving tire. Price, $1.75.—Motor Supplies Mfg. Co., 21 Fifth Street, N. E., Minneapolis, Minn.

Cylinder Reboring Tool

This is a simple, compact tool designed especially for reboring cylinders. It is belt-driven and is provided with three cutting heads, so that three cuts can be taken—the last cut is said to produce a smooth surface because of the width of the cutting edge. Price, No. 1, $175; No. 2, $200.—Machinery Co., Boston Block, Minneapolis, Minn.
